come. The situation might be reminiscent of the Cambodian experience of recent years, where a ruthless and irresponsible leadership evacuated the cities and forced an entire country into an unnecessary disaster. Imagine that situation in your community, among your friends—perhaps worldwide!

However, even in the worst of disasters, there will be some survivors. If not us, then our friends or relatives. Perhaps our children or grandchildren will be among those fortunate survivors. There also will be some amateur radio operators. Perhaps the best thing that we can do for these people faced with a completely unknown and hostile environment is to ensure that they have every possible assistance available to help them through the crisis.

In communications, that assistance means that in a world where the established public system is no longer available, the technical preparations of amateur radio operators may make the difference between life and death for countless hundreds of thousands. It could be the final foothold in their struggle for survival. After all, assistance during disasters is one of our key elements, and a justification for an Amateur Radio Service. Only amateur radio operators can supply an organized communication system from almost every community in this country. Only amateur radio operators can supply this system with a substantial portion of the surviving equipment easily made operational after the shock of a nuclear explosion. Citizens Band equipment for the most part would be rendered totally useless by its unprotected reliance on semiconductors and its tendency for

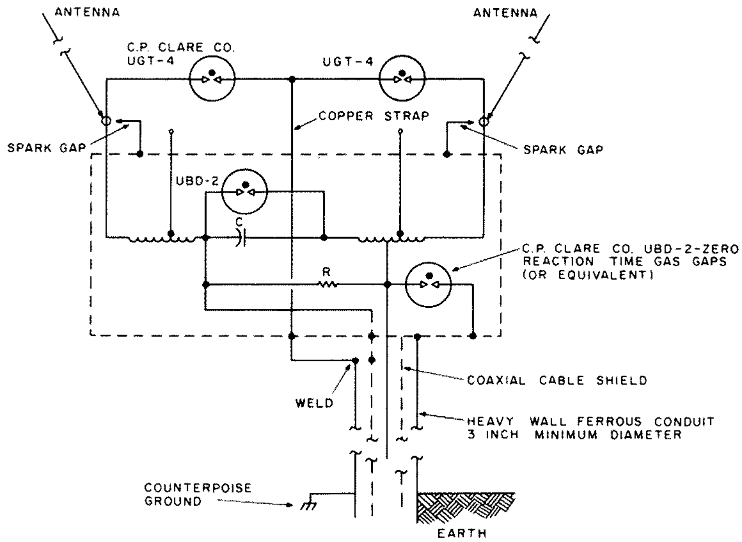

Fig. 2. Suggested use of gas gaps in an antenna balun. Note that this approach uses a thick-wall conduit around the coax.

total disorganization even in times when there is no crisis.

The job of amateur radio equipment protection is easy once we realize that it does not need to be difficult or complex. Most any technical or non-technical operator can accomplish *some* EMP protection on short notice, with a very small outlay of money. The objective is to safely bypass your equipment and any incoming connections when they are presented with an EMP signal composed of 40 to 50 kV and current in the order of 1,000 Amperes.

It is interesting to note that much of the EMP protective equipment available today has been designed since our country stopped testing nuclear weapons. As a result, none of it has received the only true test of reliability—on-the-job testing—although EMP simulators are used.

Because of the lack of widespread testing capabilities, the only really proven method of protection is also the simplest. Under this approach, all equipment to be protected should be disconnected from all external wires and

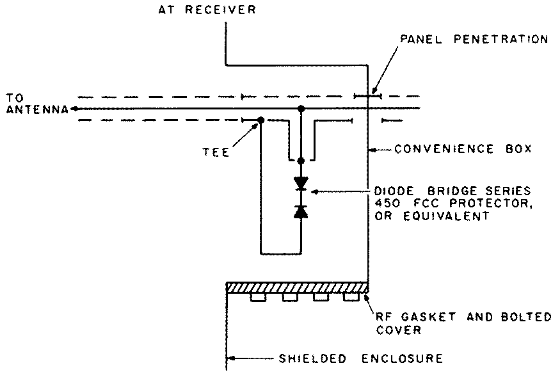

Fig. 3. Coaxial tee protectors used in a receiver circuit.

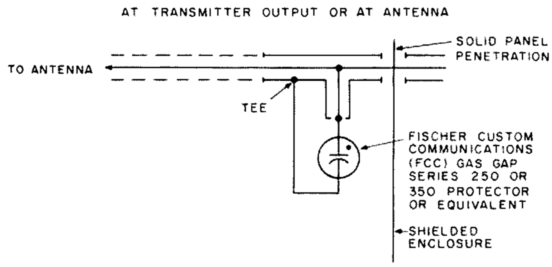

Fig. 4. Coaxial tee protectors shown in a transmitter circuit.

stored in a thoroughly sealed and shielded box. The box should have no holes where any kind of energy can get in and should have a skin made of 18- to 26-gauge metal to provide magnetic shielding for the equipment inside.

Since the civil-defense planners expect to have Americans moved to a safe location 30 to 200 miles from their community, depending on the nature of threat to that community, the equipment should likewise be moved to a location 30 to 200 miles from the community.

Keep in mind when storing your equipment that power supplies also should be shielded and stored with

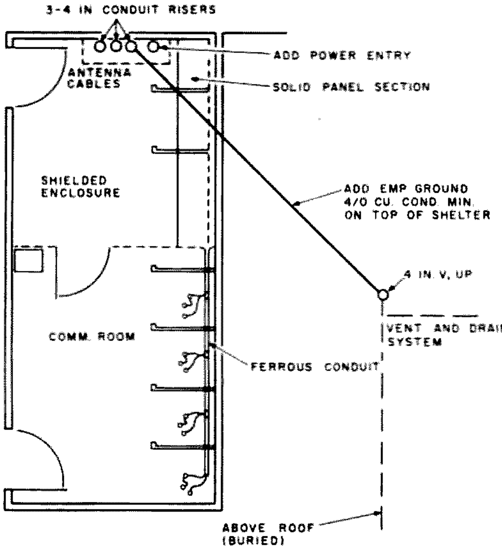

Fig. 5. Suggested layout for communications room with remote operation of equipment.

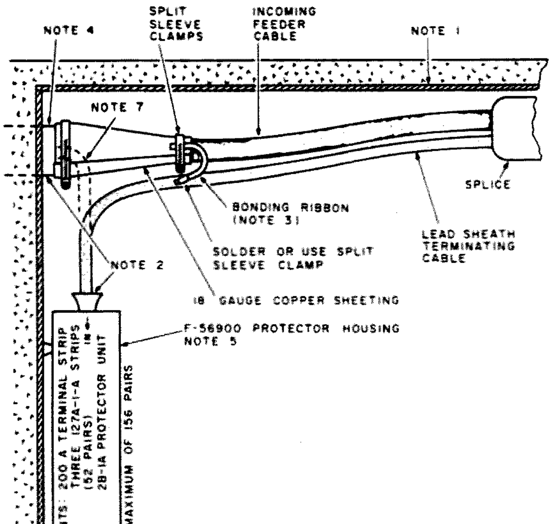

Fig. 6. This is one recommended method of protecting a telephone cable system against EMP transients. Note the heavy emphasis on shielding. The numbered notes refer to detailed construction specifications.

your equipment because they are just as susceptible to an EMP transient signal as is your sensitive transmitting and receiving equipment. A publicly-released 1970 Department of Defense publication suggests that if equipment must be used during a threat of nuclear attack, at least one set of equipment (and likely more) should be held in reserve in the event of any equipment failure. In the ideal case, ham operators should have a reserve available due to equipment failure caused by every succeeding attack.

Good grounds are very important to EMP protection, and antennas should be well grounded. But a smart operator would keep a longwire and tuner stored as if to be used for Field Day for, in any emergency, the antennas can be expected to take the brunt of the effects and may need to be replaced in the fastest time possible.

The Department of Defense publication *EMP Protective Systems* suggests several approaches which should be used if you're going to shut down for a while in anticipation of an attack. First, you should open the master power switch at your service entrance. Second, all circuit breakers should be opened and all critical equipment should be turned off or disconnected.

When the equipment and power are to be restored, all circuits should be checked for arc-overs or damage before power is restored. Be sure to disconnect telephone and cable television connections, because the advice indicates that there

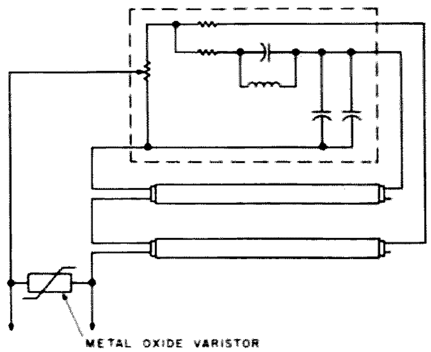

Fig. 7. This is a typical varistor installation applied to a fluorescent lighting circuit.

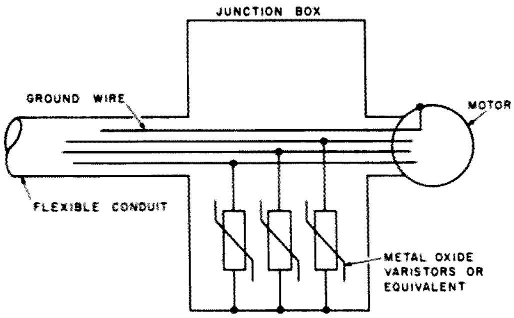

Fig. 8. This is a suggested circuit for EMP protection of a 3-phase, 4-wire motor using metal-oxide varistors (MOVs) connected between each hot wire and ground.

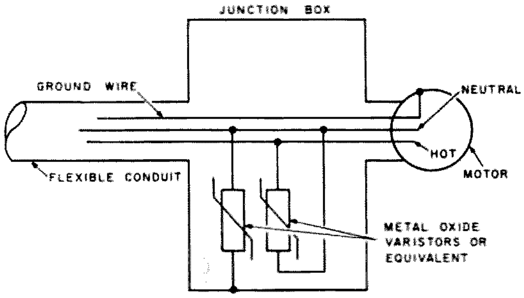

Fig. 9. Single-phase motor protection using MOVs between hot wires and ground.

could be a problem with *any* wire coming into your home. Since the EMP energy in long overhead wires can be extremely hazardous, be sure people stay away from these wires during a time of possible attack.

If you must have some radio equipment operating, dig out your old tube-type equipment and use it. Tubes are much less sensitive to high-voltage shocks and are more likely to recover. It is felt that less protective shielding is necessary for broadcast receivers with loopstick antennas or receivers with short antennas, including two-meter equipment. Again, however, because there are so many unknowns, a wise operator would most likely consider any equipment in full use to be vulnerable.

More advanced EMP protective measures which allow more operating versatility also have been published under the name of the Defense Civil Preparedness Agency and may be obtained from the Federal Emergency Management Agency in Washington, DC (ask for publication TR-61-B). These approaches to the problem center around the use of gas-gap arrestors, metal-oxide varistors (MOVs), coaxial tee protectors for antenna cables, and improved grounding. Some of their suggestions are described here, so you can start on your protection right away. The approach requires some expense and would be used if you would anticipate operating during a nuclear threat.

Improved grounding of a tower is extremely important for supplying a low-impedance path to ground for EMP current. The suggested way to accomplish this is shown in Fig. 1. The tower should be connected to the ground rods using 4/0 wire.

An alternative is to install 20 radials about 12 to 18 inches below the surface, using ½-inch copper tubing. The approach could get very expensive at today's copper prices but would provide an undisputably super ground for your vertical. Be sure to connect the outside of your antenna feed cable shields to the ground. Any control cables going up the tower should be shielded in threaded conduit so there is a perfect conductive shield all along the line.

A particularly sensitive part of an antenna circuit is a balun at the antenna feedpoint. The best way to protect a balun is to provide "zero reaction time" gas-gap arrestors in parallel with all balun capacitors and inductors. Be sure to have the breakdown voltage of the gas gap higher than that which you would expect under normal operations, even under unusually high swr conditions. Gaps can have breakdown voltages ranging from 220 volts to 30 kV and have current ratings ranging from 3,000 Amps on up.

The amount of time that any one gap arcs over is a factor to be considered when selecting the gap. Almost any gap can sustain a large number of low-current arc-overs, but only a few very-large-current arc-overs during its life. The specifications for each gap should be consulted if it is also to handle lightning-arresting chores in addition to EMP protection. Also, most gaps capable of EMP protection are labeled as such.

The characteristic capacitance of each gap is of

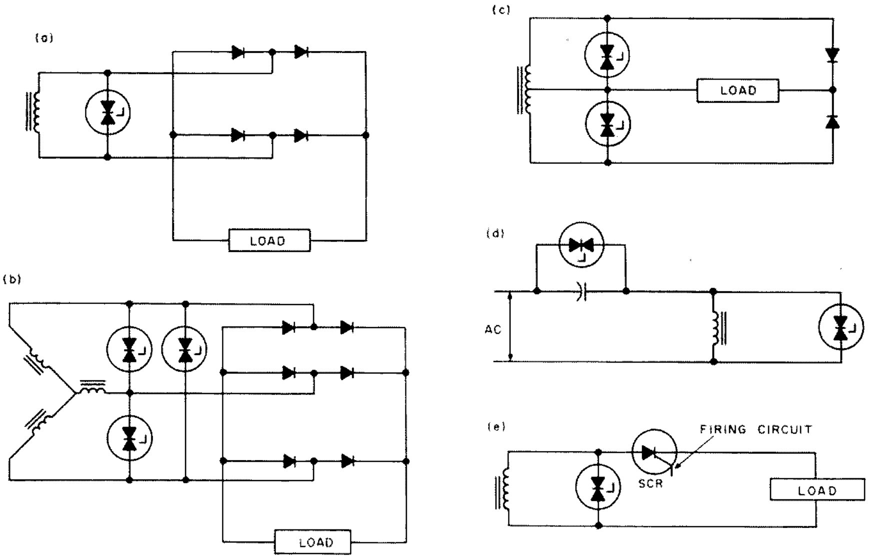

Fig. 10. Various EMP protective circuits for several typical circuits.

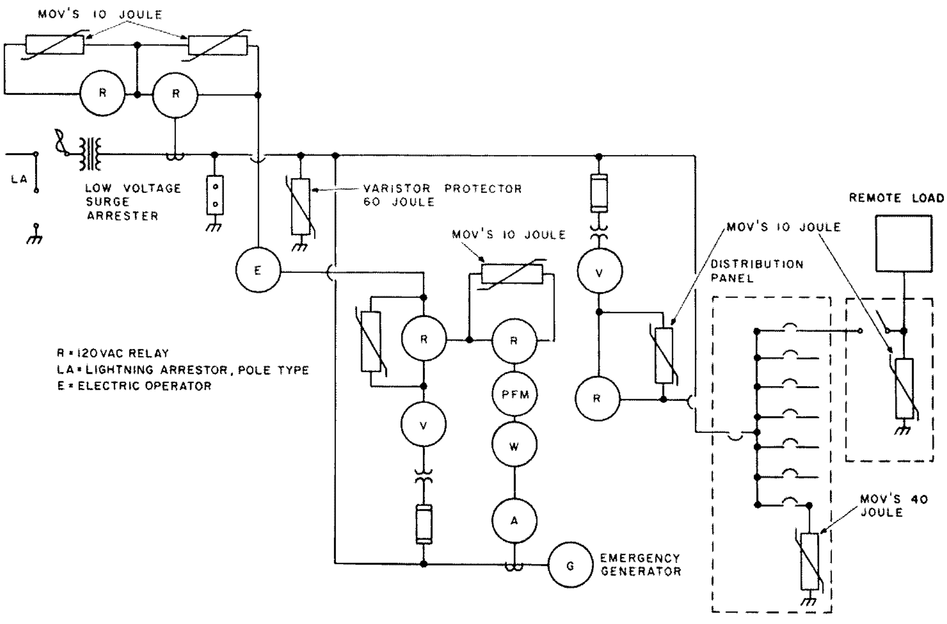

Fig. 11. Full-blown EMP protection for supplying power to communications equipment.

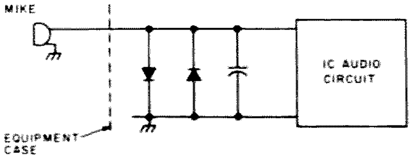

Fig. 12. Switching diodes may be used to protect very short wires. Use 1N3653s and a 0.1-μF, 500-volt capacitor.

considerable importance in rf circuits since the interelectrode capacitance between gap electrodes can cause additional capacitance to be put into the circuit along with the gas gap. This capacitance can be on the order of 2 to 15 pF or more, depending on the type of gap. The capacitance can be reduced by connecting two gaps in series. If you use that approach, be sure to put a 1-megohm or higher resistor (about 1 Watt) across each gap to equalize the voltage between gaps. Keep in mind, too, that connecting two gaps in series roughly doubles their breakdown voltage. An example of the use of gas gaps in an antenna balun is shown in Fig. 2.

At the transmitter or receiver, you may use a gas gap or tee protector as shown in Fig. 3. The diode shown here is a silicon type. While this diode has a fast reaction time, it may not be able to sustain the needed current, and should be preceded by a gas gap at a point closer to the antenna. Fig. 4 shows a gas gap connected in a transmitter circuit.

If you want to go first class and prepare the entire shack (Fig. 5), you could be in for a very expensive project, which may not be necessary if you can shut down your equipment as discussed above. However, if you wish to take that step, the FEMA recommends that the shack should be *completely encased* in 18- to 26-gauge galvanized sheet metal! To provide complete protection, the treatment includes the door and ventilation facilities. The sheet metal should be folded at the seams and soldered, with a strip of tinned-metal tape covering the seam.

Telephone landlines should be brought into the shack via 50 to 300 feet of conductive conduit which is welded to the enclosure at the point of entry. The lines should be terminated in gas gaps, metal-oxide varistors, or both. Fig. 6 shows an example. Even your lighting system should have MOV protection as shown in Fig. 7.

Ac power supply lines should have MOVs at all critical points. FEMA recommends that MOV ratings should exceed the stored inductive energy of the preceding transformer and also should exceed the no-load transformer current. Typical varistors have ratings of 40 joules (some are in the range of 10 to 200 joules) and should be installed at 40 joules per phase of the ac line. Four 10-joule varistors connected in parallel will provide the needed 40-joule protection. Electrical distribution boxes and control boxes, of course, should be thoroughly shielded. FEMA recommends that doors and openings should be fitted with rf-shielding gaskets and conductive epoxy.

Don't forget the ventilation system, where all motor wires and switches should be thoroughly shielded and protected with MOVs. Some additional circuit protection approaches may be seen in Figs. 8 through 12.

Of particular importance is the emergency generator to be used. All important wiring should have MOV protection. Shielded conductors should be used for best results and the shields should be grounded. ■

EMP Protection Equipment Sources

Some EMP protective devices are not easily obtained. I have found that even a local distributor cannot always obtain information about them. Following is an updated list of sources. Those with asterisks (*) have expressed their interest in selling the equipment by sending me information when I specifically requested information about EMP protection.

A Split Personality for the KDK FM2015R

A simple modification to your KDK FM2015R will give you the capability to receive on one frequency stored in memory and transmit on another. This modification gives you the newer FM2016's capability to operate with nonstandard offsets without an additional crystal. It requires two diodes, a piece of wire, no holes, and less than half an hour. The rig may easily be returned to original configuration whenever desired.

A different form of this mod was described in some Amateur-Wholesale Electronics notes concerning MARS-CAP modification, so I can't take credit for the original idea. I'll first describe how the modification functions, then go through a step-by-step modification procedure.

The resulting front-panel performance is as follows: Select Mode A. With the memory-select switch at OFF, you have simplex operation on the dialed-in and displayed frequency. Selecting memory position 2 will allow you to receive on the frequency stored there, which is displayed as usual. When you transmit, however, the memory internally shifts to the frequency stored in channel 1. This frequency is displayed while transmitting, and the display shifts back to your channel 2 receive frequency when the mic button is released.

Channels 3 and 4 work the same, with channel 4 functioning as the receive channel, switching automatically to the frequency stored in channel 3 on transmit. If either channel 1 or 3 is selected, simplex operation on those channels is the result. All that for only two diodes!

Here's how it works: On transmit in the unmodified rig, a transmit oscillator is diode-switched on by +9 volts from the front panel MODE switch. We locate the wire which runs to the "A" oscillator position (which has no crystal installed) and run switching diodes from there to two places.

The first diode goes to the simplex crystal position, activating it on transmit. The second diode goes to one of the two memory-select lines (A0 and A1) which select the memory channel. In an unmodified rig, the same memory frequency is used on both receive and transmit. If you trace out the schematic,

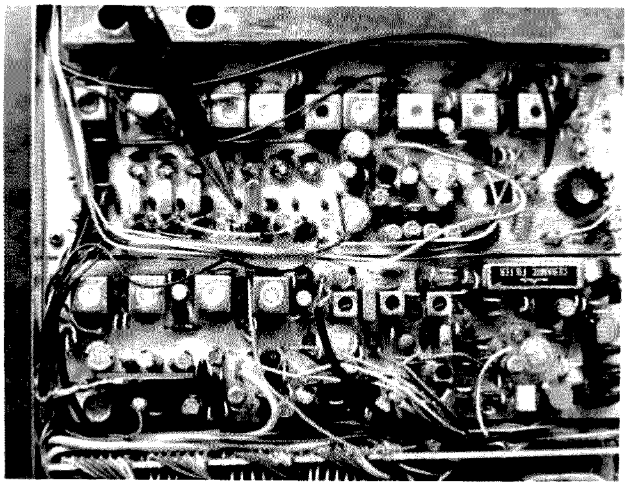

Photo A.

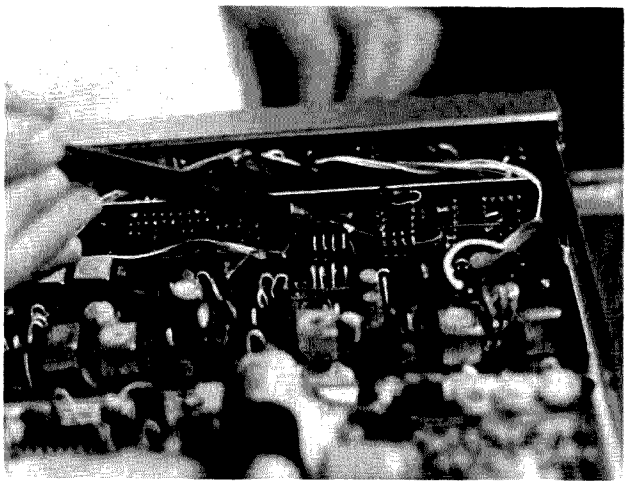

Photo B.

you will see that in the original configuration when memory position 2 is front-panel selected, +9 volts is routed through this memory switch to memory-select line A1. Or, if memory position 3 is selected, AØ is taken high. Memory position 1 requires both AØ and A1 to be high, and position 4 requires neither to be high. If we modify things to make AØ high on transmit only, then memory position 4 on receive becomes 3 on transmit, and 2 becomes 1 on transmit. This switching is done with diodes to avoid interfering with other functions.

To perform this mod, remove both top and bottom covers from the rig. With the rig right side up, locate the three crystals on the transmitter board. (See Photo A and ignore the fourth crystal which I installed for another offset.) A terminal post corresponds to each crystal position. A yellow wire is connected to the first unused crystal position, which is the fourth one in from the outside edge of the board. The pencil in the photo is touching this terminal.

Note that this wire is connected to the "A" MODE switch position and is switched to +9 volts on transmit. Remove the wire from this terminal post. You will run two diodes from this yellow wire, and you will need to mechanically secure this junction somehow. I slipped a piece of spaghetti over the terminal and tied the wire/diodes to it. However you do it, the first diode is soldered from the yellow wire to the first crystal position's terminal (the one with the brown wire). The diode points at the brown wire (cathode to brown wire) and will activate the simplex oscillator on transmit.

The second diode's anode is also soldered to the yellow wire. At this point, the yellow wire should form a "flying tie point" with the two diode anodes. Attach the cathode (point) of the second diode to a length of hookup wire. Route the free end of the wire toward the front of the radio to the control board and connect it to the AØ pad. This control board is accessible from the bottom of the radio and is located near the front panel. See Photo B. The pencil points to pad AØ. The wire attached to the pad is the one I added for this mod.

The AØ and A1 pads are designated as such on the component side of the board and have white/brown (AØ) and white/black (A1) wires attached to them on the component side. This completes the modification.

Verify that the rig will operate now as described earlier. This mod is totally "safe" in that the rig can't be harmed by incorrect front-panel switch settings. MODE switch positions B and C are still available for nonstandard offset crystals if desired. The rig's operation in all other respects is unaffected.

The only problem I encountered was that the simplex transmit oscillator didn't function until the yellow wire and diodes were isolated from the fourth oscillator terminal as I have described. If you feel like experimenting, leave the yellow wire connected and solder the diodes directly to the terminal. If it works (if the transmitter puts out power), then you win. If not, then isolate the wire/diodes as I described. Please send an SASE if you have any questions.■

Building for Beginners

—happiness is a hot soldering iron

Paul M. Danzer N1II
2 Dawn Road
Norwalk CT 06851

I have authored several short construction articles in the past year or two and each time their publication was followed by a flurry of letters asking for help in selecting parts and building the circuit. This mail suggests that a number of hams without very much electronic construction experience would still like to home-brew their own.

For this reason, I have put together a set of suggestions and hints which answer the most commonly asked questions. The next time you see a circuit or gadget described in *73* or elsewhere, don't be shy—go ahead and build it! You'll be delighted with the results.

Where Can I Get the Parts?

The most critical part of building anything these days is obtaining the parts. Years ago, the corner radio store carried almost anything you wanted, and if you lived in a metropolitan area you could always go down to "radio row" where there was a cluster of such stores. Today, your best bet is either the mail-order ads in the back of this magazine or the Radio Shack chain of stores. Radio Shack carries a line of the most commonly used parts and has stores scattered throughout the country.

The mail-order advertisers in the back of this magazine usually list common parts and prices for immediate order. Most of them offer catalogs, either free or for the postage, and are geared up to ship your order within a day or two after receipt. They have been advertising for many years, and the acceptance of their ads by *73* on a continuing basis shows that they deal fairly with their customers.

Try to take advantage of the "two-for" offers. Even if you have no immediate use for the extra parts, keep them around and you will probably find a use for them in some future construction project.

Resistors and Capacitors

Unless the magazine article states otherwise, use half-Watt resistors. They are most commonly available, and if a higher wattage is needed, the article will say so. If you are squeezed for space, quarter-Watt units can be used—again, as long as the article says nothing to the contrary.

Don't worry about the seemingly oddball values specified. Resistors generally come with 20%, 10%, and 5% tolerances. Using 10k Ohms as an example, Fig. 1 shows the relationship between the standard values and these tolerances. Today, most people use 10% values primarily because they are the most commonly available. If the

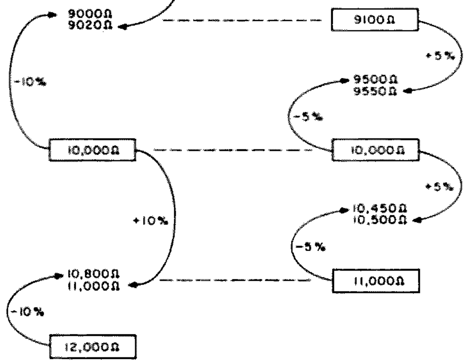

Fig. 1. Standard resistor values. Those in boxes are standard commercially-available resistors.

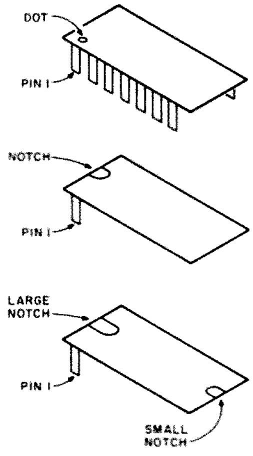

Fig. 2. IC pin locations.

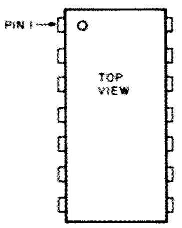
article does not say anything else, you might stick to 10%. You can always use a resistor with a better tolerance (10% instead of 20%, or 5% instead of 10%). If you need 5% and can find only 10%, buy a handful of 10% resistors and check them with an ohmmeter to select one that falls within ±5% of the value required.

Capacitors have both a value and a voltage rating. You can always use a cap that has a voltage rating higher than the amount needed. For most capacitors, you must stick to the value needed but you can always use the larger-than-specified electrolytic cap when it is used for bypassing or filtering a power supply voltage. Just be careful to wire it in with the polarity shown in the schematic.

Transistors and FETs

Generally, you will have to stick to the type specified in the article. Substitutes can be used and you can pick a substitute by looking at the substitution guide printed by a number of suppliers and distributors. Radio Shack, GE, and Motorola all have hobby lines of transistors and substitution guides where you can look up the device you want; the guide will give you their substitute number. When you do substitute, be careful of the connections. Often a substitute will be very close to the original part electrically but will have a different mechanical package and/or lead arrangement.



Integrated Circuits

Let's assume that the circuit you are building uses a very common amplifier known as the 741. There are perhaps twenty versions of this amplifier, with twenty different part numbers. Each of the part numbers includes the digits 741, with the rest of the digits telling you the temperature range and mechanical package. For most uses we don't have to be concerned about the temperature range, but the pin numbers for connecting to the amplifier are very much of interest. Compare the pin numbers of the amplifier as shown in the schematic with the pin numbers of the actual part you buy.

Occasionally, the article will specify an amplifier such as the 741 and show it as a single amplifier in an 8-pin package. You might be able to obtain only a dual 741 or two 741 amplifiers in a 14-pin package. This is perfectly OK; just ignore the second amplifier.

Integrated circuits are available most commonly in "in-line" packages having 8, 14, or 16 pins. A round dot usually marks pin 1. Sometimes a notch tells you where pin 1 is, and occasionally you have to cope with a dot and two notches. As Fig. 2 shows, the dot takes precedence over the notch, and if there is a notch at both ends of the package, the larger notch tells you where pin 1 is.

Unlike tubes or transistors, the manufacturer's data sheets usually picture integrated circuits from the top. Therefore, when you are wiring them from the underside, remember that pin 1 is now on the other side of the package as seen from the bottom of the circuit board (Fig. 3).

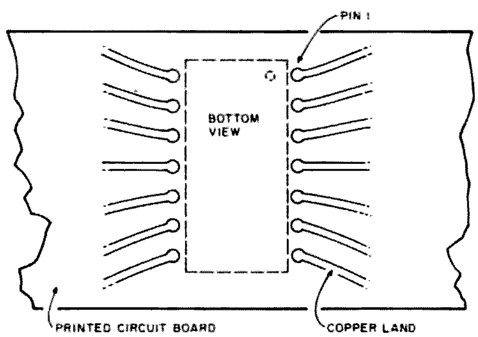


Fig. 3. Pin 1 transposition.

Diodes

Power-supply-type diodes have both a current rating and a voltage rating. You can substitute any diode which has a rating equal to or greater than the original numbers. Small signal diodes used as switches usually can be substituted for at will. Most ham circuits use a maximum of 12 volts (sometimes labeled 13.6 volts if the equipment is for mobile use). Therefore, if the circuit calls for a small signal silicon diode, almost any other silicon diode will do. Fig. 4 shows the most common markings of the diode package.

Zener diodes, used in voltage regulators, have both a voltage rating and a power rating. You must use the voltage rating called for, but you can always use a higher-power-rated diode.

Power Supply Connections

Fig. 5 shows a simple 2-transistor amplifier. With today's solid-state circuits, usually only one power-supply voltage is used and, as shown in the figure, you simply tie the identically-marked points together and connect them to the voltage required. If the schematic does not show differently, the power-supply return lead (in this case the minus 9-volt lead) is tied back to all of the ground terminals.

Jacks

Here you can substitute at will. Just remember that the most commonly used jacks have one side exposed and will connect to the chassis (ground) if they are not insulated by wash-

Fig. 6. Wire sizes.

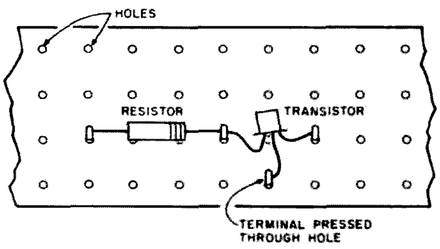

Fig. 7. Use of perfboard.

ers. If you need a two-conductor jack, and one lead is not supposed to be grounded, you will either have to mechanically insulate the outside of the jack from ground or get a three-conductor jack where you use the two inner conductors and ignore the third (grounded) lead.

Cable

If the circuit you are building is not used at VHF and a piece of coax is called for with a length of 12 inches or less, the coax is being used mainly for its shielding capability. You can safely ignore the impedance and pick a piece of coax on the basis of being able to fit it into your box mechanically.

Wire

Unless used for high-current leads, most solid-state circuits use just a few milliamperes per stage. Therefore, there is no reason to use wire sizes larger than number 22 or 24. As shown in Fig. 6, the lower the number the larger the wire diameter. Pick wire which is mechanically convenient. Soft plastic insulation strips very easily and conveniently, but if you have to solder a number of them in close proximity, the plastic tends to melt and burn, generally making a rather unsightly mess.

Printed Circuit Boards and Breadboards

Some construction articles provide either a PC-board layout or a commercial source for purchasing the board. If a layout is given, you can use the PC-board kits sold by several suppliers to make your own. However, if no board is suggested, you always can use a breadboard-type construction to build the circuit. Most hams have one or more breadboard circuits, neatly enclosed in a box, which have been operating in their breadboard form for many years. Even if your construction does not come out very neat, the flaws will be hidden by the enclosure you put the circuit in.

One of the simplest construction techniques uses perforated board such as that sold by Radio Shack, Vector, and others. The circuit is laid out just as it appears on the schematic, and every time a connection must be made, a small metal terminal or clip is inserted in a hole and the leads soldered onto the terminal (Fig. 7.).

Alternatively, general-purpose PC boards also are commercially available. They are arranged in a fixed pattern and, as shown by the dotted rectangle, integrated circuits plug in adjacent rows of holes (Fig. 8). A bus-bar system of feeding ground and voltage is used, where one bus is connected to the supply voltage and jumpered to the IC pin where required. Transistors and other parts can be mounted where convenient. A second bus is used for ground.

Also commonly available are small carrier boards which will allow you to wire up one or two integrated circuits (Fig. 9). Other parts are jumpered from one terminal to wherever required.

Generally speaking, sockets or molex® pins are a good idea for mounting integrated circuits. If you do have a problem, you can now unplug the IC and test or substitute without a massive and messy unsoldering job.

Plan It Out and Then Build

Take a careful look at what parts are required and make sure you can obtain them. Plan the layout of parts and decide what you are going to enclose the circuit in and where the jacks, connectors, and controls will be located. Don't hesitate to call for help. Often an experienced ham in the area can offer an immediate solution to your unique problem. But if this does not solve the problem, you can drop the author of the article a note. Enclose an SASE, and help will probably be on its way quite quickly. ■

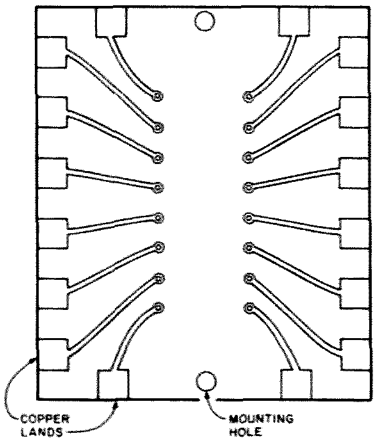

Fig. 9. Single-IC carrier board.

Glenn Jacobs KC7M
Poverty Flat AZ 85925

Coping with PC Boards

—it's not easy to be virtuous

"Admit it. You'd really rather build it. Any idiot can plunk down a charge card."

"Well, yeah . . ."

"Glenn, if you build it, it will give you pride and experience, and you'll know how to service it yourself."

"Yeah, but . . ."

"And it wouldn't cost nearly as much, and nobody would have one just exactly like yours."

So, I'm building. And my inner voice was right about everything it said. But there are a few things it *didn't* tell me. I found out the hard way, and I'm telling you so *you* don't have to "re-invent the wheel," like I had to.

I'm building. But so help me, when I see those full-page, full-color ads and a toll-free number and the sign of the yellow and orange overlapping circles, it's hard to keep at it. I could have any equipment I want for just a phone call and twenty "easy" payments. The path of virtue is harder.

Designing It

In the first place, I don't know much about vacuum-tube circuits and even less about solid state. Fortunately, I don't have to. The League[1] publishes *Solid State Design for the Radio Amateur.* It's a "cookbook." It shows three varieties of any circuit you could want—all pre-engineered and tested.

Redesigning It

Now, even with a cookbook, I can make mistakes. In fact, it's about even odds that I will make a mistake in a one-device gadget. It is far beyond me to put forty "stages" on a board as big as a *73* cover and have them all work. I decided to put each stage on a separate board and plug 'em all into edge connectors. That way if (when!) I make a mistake, I won't have to tear everything up.

I mailed off[2] for some PC board. It took three weeks to get here. They didn't send it until my check cleared.

Whittling It

PCB is funny stuff. I couldn't trace anything on it. I couldn't find any kind of carbon paper that would make a mark. Finally I rubbed yellow crayon on the copper and was able to trace faint lines. I cut on the lines and peeled up the unwanted foil in little-bitty strips with a point of a knife. It took half a day. But it worked. I got a nice little 40m CW receiver for my trouble.

Buying It

For my next project, I just sent off for ready-made custom boards.[3] They were nice, neat, correct, beautiful, and even had the parts placement marked. They worked perfectly. I made a mate for the last project. But I wanted to do these boards myself.

I sent off for ferric chloride.[4] This time I called up and told 'em my card number and they had the stuff delivered to my door in about three days.

Mixing It

The ferric chloride is a black, gritty powder. I mixed it with hot water in a plastic jug. The water got hotter. The powder that got on my hands turned into a brown goo all by itself and began to sting. I went and washed it off. When I came back, the grit I had spilt on the floor had turned into a nasty glop. That stuff absorbs water right out of the air! I wiped it up. The floor is now permanently stained several shades of brown, black, green, and gray.

Etching It

Anyway, now I was ready to begin. Or was I? I cut out a little piece of the high-priced board and drew a circuit on it in ink. I laid it in a plastic dish and poured some of the smelly brown juice over it. An hour later it looked gritty. Two hours later it was covered with a fine black sediment. I rinsed it in the sink and every bit of copper was gone. The thing might still make a banjo pick, but it would not make a circuit.

Resisting It

I cut out another piece. This time I drew my design with a felt marker. I baptized it for two hours in the ferric chloride soup and, behold!—a printed circuit. The remaining foil was rough and gritty—about half eaten up. But it would do. Now I knew for sure what to do. Very carefully I designed the first board. I felt-marked it and laid it away in the tobacco juice. In the morning there wasn't enough copper left on the

board to tell what it was supposed to have been.

Next I tried crayon. I suppose if crayon were the only resist in the world, we might make a go of it, but we wouldn't like it. It turned out rough and ugly. By now I wasn't trying to make any particular kind of board. I just wanted to see what would get me decent results.

Cursing It

Oh! I found a lump of etchant I had missed before. I stepped on it barefoot and stained my sole brown. I said some words that stained my soul deep purple. After I cleaned up the mess, I went to bed, disgusted.

Dreaming It

Suddenly I sat up. I had dozed off and dreamed I was painting a pattern with a tiny brush. That mimeograph correction fluid! I had a whole case of it! Mimeograph correction fluid corrects by drying into a plastic film. And it comes with a handy little brush built right into the bottle lid. I put on my pants and waddled out into the dark to my store.[5] There it was, cartons and cartons of it. I brought one in and annointed a little rectangle of copper with abstract designs and flooded it with the slop from the jug.

In the morning I rinsed it off and scrubbed it clean at the kitchen sink. Beautiful. My design was perfectly preserved in glittering copper.

Sharing It

Finally I have found *The Way* to do it. And I will share it with you. Just send a dollar and a double-stamped SASE to Glenn's Trading Post at Poverty Flat, Arizona 85925. I will send you a bottle of gen-u-ine Army surplus correction fluid complete with a nice little applicator brush built right into the lid. Guaranteed to delight you. Correct your stencils. Paint your nails purple. Make your own PC boards. (Who knows, it may even remove warts.) This is the best stuff since snake oil. You can even see your pencil lines on the foil through the fluid.

Drilling It

By 'n by I had the first board ready for parts. Nearly ready for parts. Gotta drill it. All my drills are too big. I went to a dozen hardware stores within a hundred miles. The smallest ordinary drill bit is a sixteenth of an inch. It's positively teensy. But the components just fell out of the holes. Even after I soldered them. The best I could do was bend the leads over hard after poking them through the holes. Then they would stay in place long enough to be soldered. But the holes were so large it left a quarter-moon gap around each lead. It didn't look neat. It didn't look professional. If I had wanted a ventilated board, I would have made a pattern of round holes on purpose.

"I need a smaller drill."

"No. You need smaller holes. Or, you need to be less picky."

"All I want is a drill half that size."

"There ain't any in eastern Arizona. You need something else."

"If it drills holes, ain't it a drill bit?"

"Not necessarily."

My wife broke a sewing-machine needle as I argued with the inner voice.

"Honey, get this broken needle out for me, will you, please?"

Grinding It

I did. A broken-off sewing-machine needle looks a lot like a little-bitty drill bit. I ground a bevel on the notched side of it with a whetstone and it looked a lot more like one. I chucked the shank into my hand drill and found it would go through PCB like a hot knife through butter. It made a neat round hole with the foil pushed up around the edge like the rim of a moon crater. And, the hole was too little for a resistor lead. But sewing-machine needles come in different sizes and for a buck at the friendly local notions counter, I had an assortment of drill blanks just the right sizes for component leads.

Concluding It

You can roll your own printed circuit boards without spending a fortune on special supplies and equipment.

You can draw your pattern right on the copper with an ordinary pencil and erase it until you get it right. You can paint directly on the board with mimeograph correction fluid. You can see your pencil lines right through the purple film. You can remove it with a fingernail. When you are satisfied with your pattern, a mixture of ferric chloride and water will etch it for you. Plain water will clean it up, with a little scrubbing.

If you can't get the size of drills you need, ready-made, you can make your own out of sewing-machine needles. ■

Footnoting It

1. American Radio Relay League, Newington, Connecticut 06111.

2. There are a lot of places. I got mine from Fair Radio Sales, Box 1105, Lima, Ohio 45802.

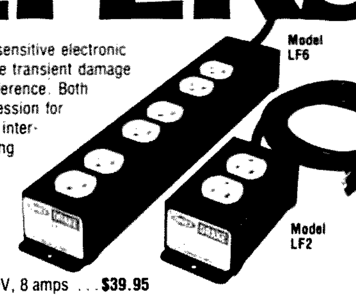
3. Again, there are several sources. Try Circuit Board Specialists, Box 969, Pueblo, Colorado 81002.

4. Meshna, Box 62, East Lynn, Massachusetts 01904. They may be out.

5. Glenn's Trading Post, Poverty Flat, Arizona 85925.

POWER•LINE FILTERS

These filters protect any sensitive electronic equipment from power line transient damage and radio frequency interference. Both models offer surge suppression for power line "spikes". RF interference is suppressed using both inductive and capacitive components. Ideal for computers, test equipment, or TV.



LF2—A duplex outlet, 120V, 8 amps . . . $39.95

LF6—Three separately filtered duplex outlets, 120V, total fused capacity 15 amps, power switch and indicator lamp $69.95

'Lite Receiver IV

—the second half

J. Richard Christian WA4CVP
600 Norton Drive
Satsuma AL 36572

S. F. (Mitch) Mitchell, Jr. WA4OSR
PO Box 973
Mobile AL 36601

This is the second part of a two-part article on the 'Lite Receiver IV™.* In the first installment (May, 1982, *73*), we described our philosophy for designing a home-brew receiver that can be easily duplicated. The 'Lite Receiver IV is the culmination of that design philosophy. The receiver completes the home-brew system which started with our low noise amplifier (February, 1982, *73*) and easy-to-build downconverter (March, 1982, *73*).

The first 'Lite Receiver IV installment covered the 70-MHz bandpass filter/i-f amplifier board and the video demodulator board. Also included was an interconnection diagram showing how all of the boards were connected together. In this installment, we describe the audio, automatic frequency control, and metering circuits. For ease of building, printed circuit board layouts and parts lists are provided. A source is provided for etched and drilled printed circuit boards for those not wishing to "roll their own."

Dual Audio Board

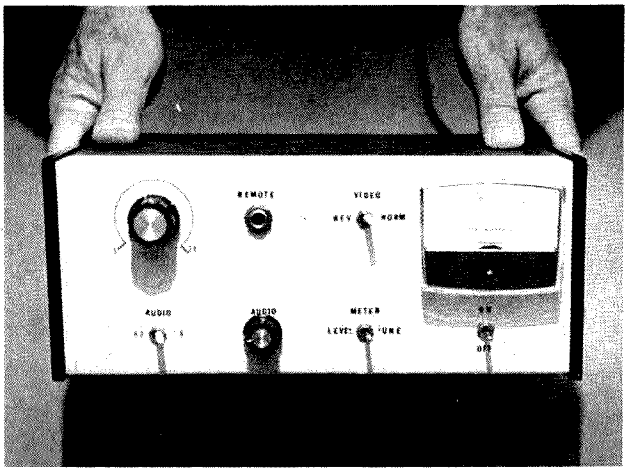
The audio circuit provides for switch selection of either 6.8-MHz or 6.2-MHz audio subcarriers from the satellites. The circuit shown in Fig. 1 is designed around Motorola MC1358 audio decoder ICs; however, RCA CA3065 or National LM3065 ICs can be used as direct replacements. The board can drive a small speaker and has a front-panel audio-level control if the speaker is used or the audio level from the MC1358s is sufficient to drive most rf modulators. Complete component cost, exclusive of the printed circuit board, should be around $15.00.

Construction

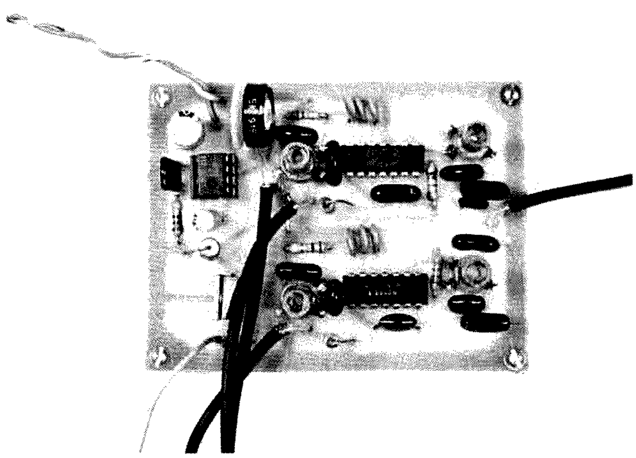
The printed circuit board and parts overlay, Fig. 2, make construction simple. We did not use sockets for the ICs; however, there is no reason not to use them with the relatively low rf frequencies involved. The coils are about $1.00 each from RCA distributors.

When building, you must decide on the options that

*'Lite Receiver IV is a trademark of Martcomm, Inc.



Front panel of the 'Lite Receiver IV.



Top view of the 'Lite Receiver's dual audio board.

you want. If you do not plan to use a speaker but need audio only to drive your rf modulator, then the LM386 and its associated components can be eliminated. In that case, the front-panel level control will not be needed, but be sure to install the two 50k-Ohm printed circuit board pots since they control the amount of audio available from the MC1358s. If the LM386 is not installed, the center pole of S1 is connected to a rear-panel jack for connection to your rf modulator. If the LM386 is installed, then the output of the LM386 is connected to the rear-panel jack for connection to a speaker or to your rf modulator. We use the complete circuit as shown so that a small speaker can be used when we carry the receiver out to the antenna to make adjustments.

If you decide that you want the speaker drive capability, replace the two 50k-Ohm PC board pots with 10k-Ohm, quarter-Watt resistors. The 10k-Ohm resistors provide fixed attenuation of the audio level from the MC1358s. The front-panel control is then used for audio level for both the LM386 and your rf modulator.

Note that picofarad-size capacitors are silver mica, with all other capacitors ceramic or electrolytic.

Tune-Up Procedure

For tune-up, it is necessary to have a signal generator or use a signal off the air. If your signal generator has modulation capability, enable the modulation and tune the output of the generator for 6.2 MHz. Tune L1 for maximum audio level and L2 for best audio (which probably won't be very good because most signal-generator modulation is AM). If the signal generator is CW only, then tune both L1 and L2 for maximum quieting. If the LM386 was omitted, adjust the 50k-Ohm pot for correct modulation level for your rf modulator.

To tune the 6.8-MHz circuit, simply repeat the above procedure with the signal generator set for 6.8 MHz and tune L3 and L4 as described.

Off-the-air tune-up can be performed using the same procedure as above. However, video will have to be detected by the video demodulator board since the audio is a subcarrier riding on the video signal. If the signal-generator tune-up method is used, it still will be necessary to fine-tune once you have a signal off the air. Simply adjust for best audio quality.

If the LM386 and a speaker are used all the time, be sure to heat-sink the voltage regulator and the LM386. This completes the audio section of the receiver.

Afc/Metering Board

The afc/metering board gives afc control for the mix-

PRINTED CIRCUIT BOARDS

Printed circuit boards are available from Martcomm, Inc., PO Box 74, Mobile AL 36601. The dual audio board is $12.00 and the afc/metering board is $15.00. Add $1.75 per order for first class postage.

DUAL AUDIO BOARD
Parts List

2 MC1358 ICs. See text.
1 LM386 IC
1 7812 voltage regulator
2 50k-Ohm PC board mount pots. See text.
1 10k-Ohm pot, panel mount. See text.
1 10-Ohm, ¼-Watt
2 220-Ohm, ¼-Watt
2 10k-Ohm, ¼-Watt. See text.
2 4-pF silver mica
2 12-pF silver mica
2 27-pF silver mica
2 33-pF silver mica
7 .01-uF disc ceramic
4 .047- or .05-uF disc ceramic
1 .05-uF disc ceramic
3 1-uF electrolytic
1 10-uF electrolytic
1 100-uF electrolytic
1 SPDT switch, panel mount
2 coils, L1 and L3, transformer-sound/i-f, stock number 130120, from RCA PM200 sound board.
2 coils, L2 and L4, coil-discriminator, stock number 130121, from RCA PM200 sound board.
1 printed circuit board, single-sided, G-10, available from Martcomm, Inc., PO Box 74, Mobile AL 36601.

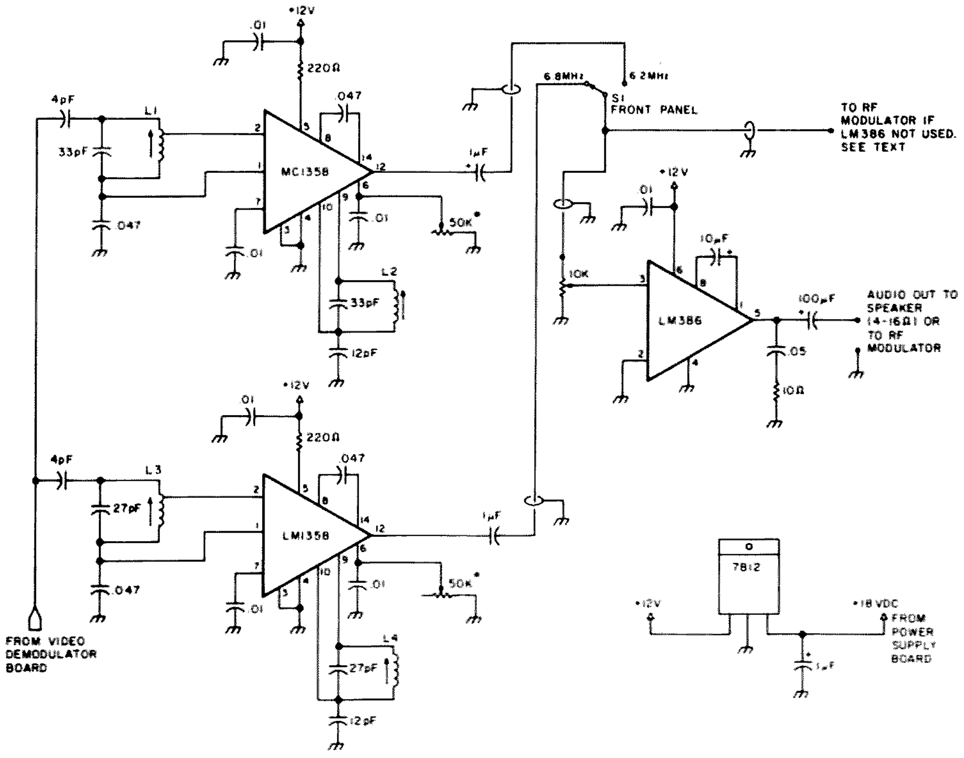


*Fig. 1. Dual frequency audio demodulator and amplifier schematic. *See text. All pF capacitors are silver mica. All others are disc ceramic or electrolytic.*

AFC/METERING BOARD
Parts List

1 LM324 IC
1 1k-Ohm PC board pot
2 5k-Ohm PC board pots
1 5k-Ohm panel mount pot
1 10k-Ohm PC board pot
2 1k-Ohm, ¼-Watt
2 2.2k-Ohm, ¼-Watt
6 10k-Ohm ¼-Watt
1 1 megohm, ¼-Watt
3 .01-uF disc ceramic
1 .022-uF disc ceramic
2 1-uF electrolytic
1 47-uF electrolytic
2 1N270 germanium diodes
1 0-1-mA meter
2 SPDT switches
1 printed circuit board, single-sided, G-10, available from Martcomm, Inc., PO Box 74, Mobile AL 36601.

er local oscillator (vto) and provides drive for a relative signal-strength meter.

The signal-strength meter is not a necessity for the receiver. Still, meters seem to impress people and we are no exception. It does serve a very useful purpose, however. The meter comes in handy for adjusting your LNA and antenna, and it gives a relative indication of signal to noise for your complete system.

As can be seen from the schematic in Fig. 3, there are four op amps used on the board. We needed three for the afc circuitry, so one was left over. We decided to put it to use to drive the meter. The 70-MHz output from the i-f filter amp is picked off through a coaxial tee coupled with a .01-uF capacitor. The rf is then fed to a voltage doubler composed of two 1N270 germanium diodes. The dc from the voltage doubler goes to an op amp connected as a non-inverting buffer. The op amp drives a 0-1-mA relative signal-strength meter.

Afc Circuit

The automatic frequency control (afc), like the metering circuit, is not an absolute necessity. But it sure is nice to have it lock the vto onto a transponder, as the vto does drift in frequency due to ambient temperature fluctuations.

It was decided to provide for afc with normal or inverted video. There is not much inverted video on the satellites, but occasionally you do run across an "upside-down" transponder. Also, on a single-conversion system such as ours, it is possible to tune in the image of a transponder. But if the video switch is in the "NORM" video position, the afc will "push" the image signal away instead of locking onto it.

Refer to the schematic in Fig. 3. At the afc sample

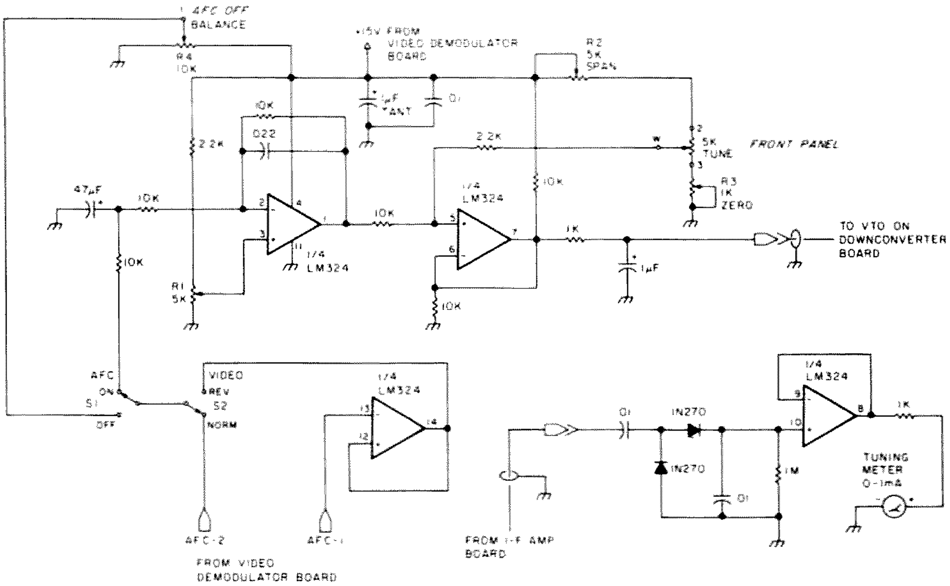

Fig. 3. Afc/metering board schematic.

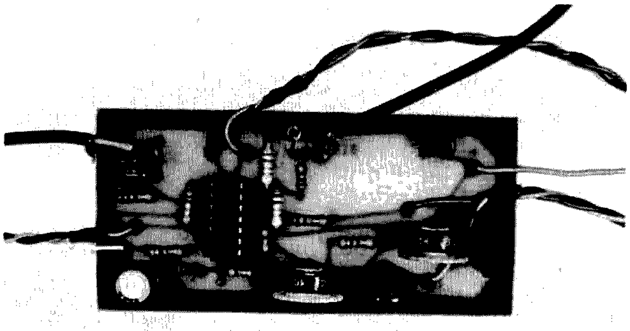
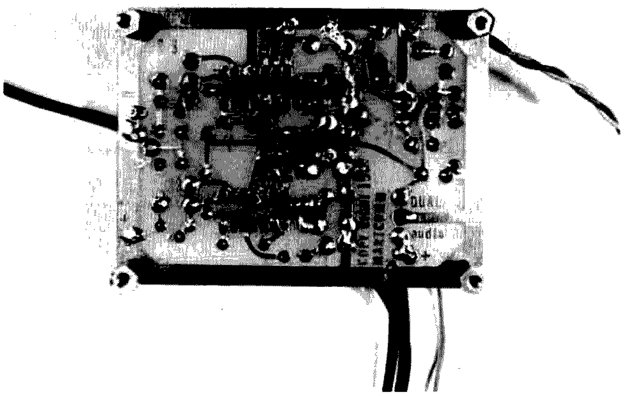


The 'Lite Receiver's afc/metering board.



Bottom view of the dual audio board.

point, AFC-2, we are not detecting a peak or a null, but instead a dc level which is compared to a reference signal at pin 3 of the LM324 quad op amp. The first op amp in the chain is wired as a non-inverting voltage comparator. Its output is summed with the transponder tuning pot voltage to supply the tuning voltage for the vto in the downconverter (mixer). A span pot, R2, and a zero pot, R3, are provided to calibrate the transponder tuning pot, since vtos have different voltage-to-frequency ratios.

The third op amp is used as an inverting buffer for inverted video. As can be seen on the schematic, the video normal/reverse switch is a double-pole, double-throw switch. This switch reverses the afc action when you switch from normal to inverted video. Also, provision was made to turn the afc off but not change the transponder tuning pot calibration. R4 sets the afc reference level the same as the afc voltage of a properly tuned transponder when the afc is switched off.

Construction

A printed circuit board layout and parts overlay are shown in Fig. 4. There is nothing critical about the construction of this board. Just use good soldering technique and keep components flat against the printed circuit board. Use an IC socket for the LM324 since tune-up of the board is done before the LM324 is installed. Do not connect the tuning pot wiper to point "W" on the PC board yet.

Tune-Up

Connect the tuning-pot wiper to the vto at this time. Connect the AFC-1 and AFC-2 points to the video demodulator board. Connect to the +15 volts regulated and dc ground return on the video demodulator board. Set the video switch to "NORM" and the afc switch to "ON."

With the LM324 unplugged, test for +15 volts at pin 4 of the LM324 socket. Tune in a transponder and measure the voltage at pin 2 of the LM324 socket. Move the meter probe to pin 3 on the socket. Then, using R1, set the pin 3 voltage to equal the pin 2 voltage. Now switch the afc switch to the "OFF" position. With the afc switched "OFF," set the pin 2 voltage with R4 to the same voltage as with the afc switch "ON." Now, remove power and plug or solder in the LM324. Connect the tuning-pot wiper to point "W" on the afc board, and connect the afc board output (marked vto) to the vto. Be sure to use coax or well-

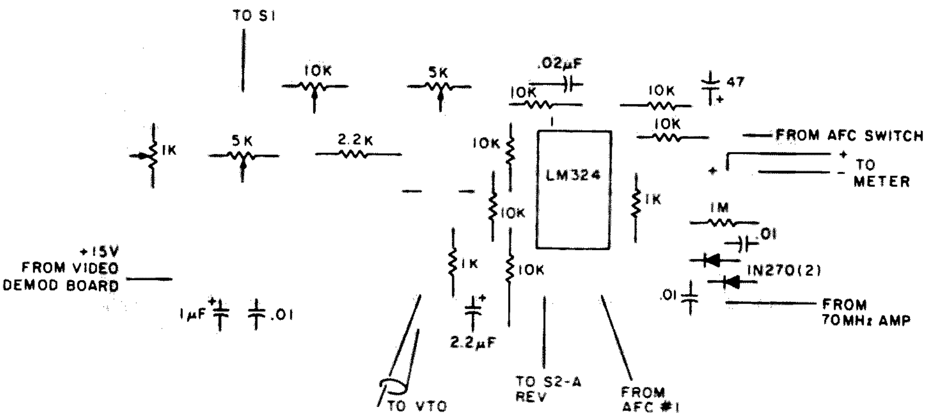


Fig. 4. PC board and parts layout for the afc/metering board.

shielded cable to connect the output of the afc board to the vto. (Usually, the vto will be remotely mounted in the downconverter, located at antenna.) The afc board output is controlling the voltage-controlled oscillator in the mixer, so any stray signal or noise spikes picked up by the cable will result in the vto being "modulated" and will cause it to change frequency with very undesirable effects on the picture.

With the afc switch "ON" and the video switch set to "NORM," the tuning pot will act like a channel switch. As the tuning pot is rotated, the afc will try to hang onto a transponder as long as possible; then, it will "jump" to the next transponder. Because of the "jump," the effect is to "switch" transponders! Finally, adjust the zero pot, R3, to set transponder #1 close to full counterclockwise position of the tuning pot. Adjust the span pot, R2, to set transponder #24 close to the full clockwise position of the tuning pot.

Now, with a 0-1-mA meter connected to the meter output, tune in a transponder and impress people.

Rf Modulator

We have not described the rf modulators that we have tried since we just haven't found a circuit that we are happy with. At present, we are using the rf modulator in our RCA video tape players. The rf modulator therefore costs only four times what the complete 'Lite Receiver IV costs!

Correspondence

Because of the complexity of the 'Lite Receiver IV, we may not have answered all your questions. We'll be glad to try to answer any questions that you might have if you include a self-addressed stamped envelope and are patient in awaiting a reply. ■

TVRO Transducer

—waveguide-to-coax transition

Trans-duc-er (trans-doo'-sar) n. Any device through which the energy of one power system may be transmitted to another system, whether of the same or a different type.

Now that you know the dictionary definition of a transducer, let's look at the satellite TV definition: the gizmo that hooks the antenna horn to your LNA.

Simply stated, the transducer is a section of waveguide 3/4 of a wavelength deep with the back closed. The waveguide is a transmission line and has a velocity factor different from that of free space. A signal-pickup probe is installed 1/4 wavelength from the back (closed end) and 1/4 wavelength from one side of the box. The 1/4-wavelength spacing ensures that any 4-GHz energy that gets past the probe and is reflected from the back of the box to the back side of the probe will be in phase with the signal arriving "head on," since 1/4 wavelength from the probe to the back of the box plus 1/4 wavelength from the back of the box back to the probe equals 1/2 wavelength. The 1/2-wavelength spacing minimizes phase distortion and signal cancellation.

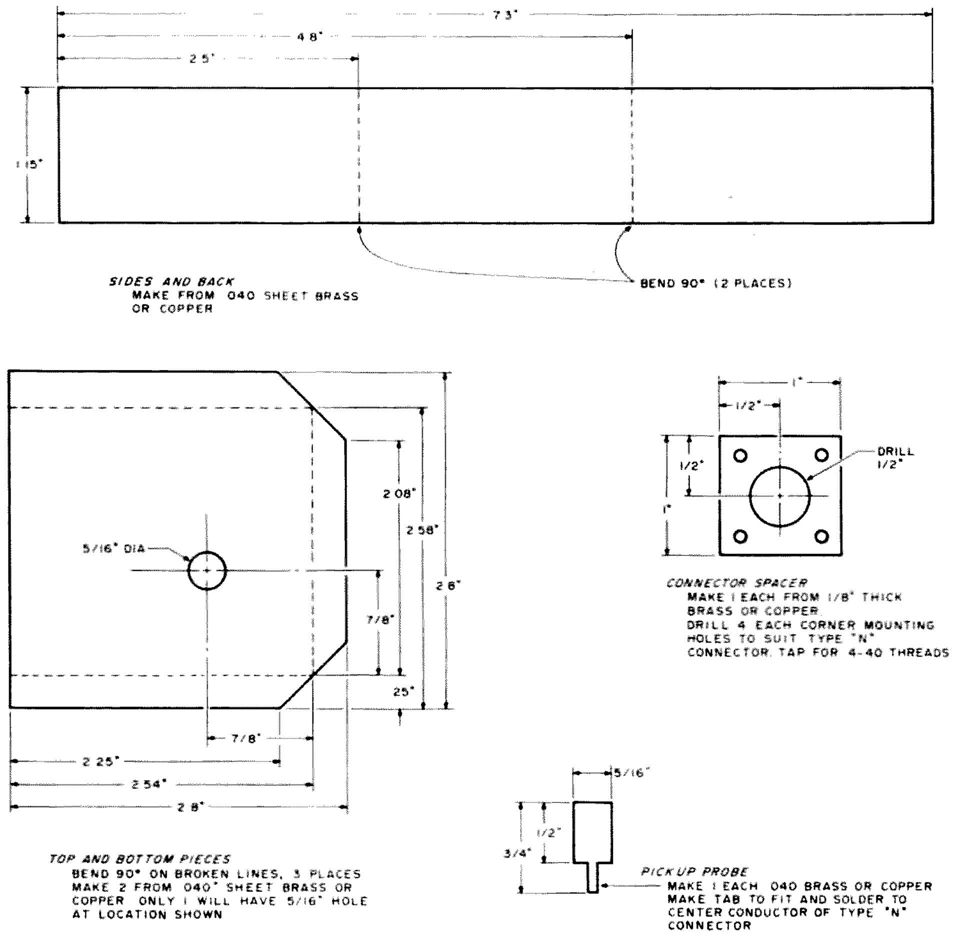

Fig. 1. Parts dimensions and bending instructions.

Two Methods

Our transducer can be built in one of two ways. If you are lucky and can find some 4-GHz copper waveguide, most of the work is already done for you. Just cut off a 2.5" section of the waveguide. Take a scrap piece of waveguide and cut a piece to fit the back of the 2.5" piece. Solder the two pieces to form a box with one end open. Make sure

that no solder gets inside the box. Using the instructions below, prepare and install the 1"-square piece, the probe, and the coax connector. This waveguide method was used to build the transducer in the photo.

If you are not lucky enough to have a friend with a source of waveguide, you will have to "bend" your own. The material needed is .040" brass shim stock or sheet flashing copper. Most large sheet-metal shops have small scraps of such material that can be purchased at a very reasonable price.

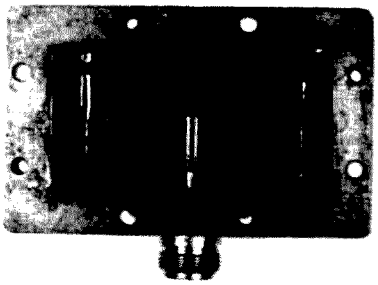
Cut the 7.3" × 1.15" piece of material and bend it to a U shape as shown in Fig. 1. Cut two pieces 2.8" × 2.8". (You probably can get the sheet-metal shop to cut the material with their shear for good clean edges.) Bend the edges of the two pieces 90 degrees as shown in Fig. 1.

Drill one 2.8" × 2.8" piece as shown. This piece will be the bottom of the box, so that looking into the front of the box, the probe hole will be in the bottom on the right-hand side. The photo shows how the probe is offset.

Thoroughly clean all pieces in preparation for soldering. Assemble the three pieces to form the box, and clamp or wire them together. If necessary, slightly bend the U-shaped piece outward to ensure a tight fit when the top and bottom pieces are installed. With a large soldering iron or small propane torch, solder all seams. Be sure that *no* solder gets inside the box. If any solder gets inside, clean it out; you want a very smooth surface inside the box to minimize interference with the signal energy.

Installing the Probe

The 1"-square connector spacer (see drawing) must be made from 1/8" brass or copper. Drill a 1/2-inch hole in the center of the 1" piece. Then, using the type N chassis-connector mounting holes as a guide, drill and tap the piece for 4-40 screws. Sweat-solder the 1"-square plate centered over the 5/16" hole in the bottom of the box (now, transducer!). Cut the pickup probe from .040" brass or copper scrap to the dimensions shown in the drawing. Solder the probe to the center connector of the type N connector. The distance from the connector flange to the end of the probe is 13/16".



End view of a transducer made from copper waveguide. Note the clean, smooth interior.

Now install the connector to the waveguide, using 4-40 screws, making sure that the flat side of the probe is toward the front of the waveguide.

Connecting to the Horn

After constructing your transducer by the easy or hard method, you still have to mechanically connect it to your antenna horn. This is where a WR-229 waveguide flange comes in real handy. If you don't have access to a WR-229, you can make one from 1/8" brass or copper. Mild steel also could be used, but is more difficult to solder. Refer to Fig. 2 for the dimensions if you have to make your own.

Solder the flange flush to the front of the transducer. Sand or file off any excess solder for a smooth transition from the flange to the transducer. Drill mating holes in the flange to mate with the flange on your horn. We use .141" hardline coax from the transducer to the LNA. This small coax can be bent easily so that the LNA can be installed directly behind the transducer.

Final Comment

We have heard of several people building horns and transducers from double-sided printed circuit board. We have gone the PC-board route, but with very poor results. Stick with the sheet copper or brass and you should get good results with a minimum of trouble. Good transducing! ■

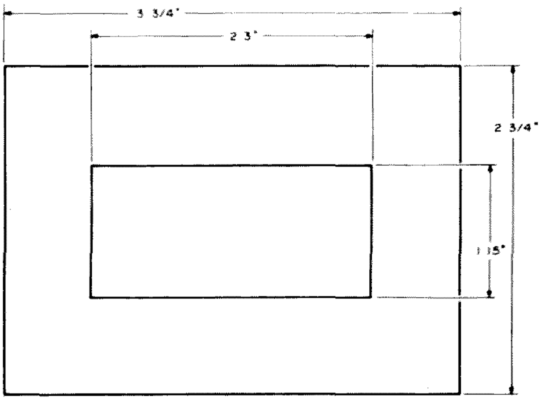


Fig. 2. WR-229 waveguide flange dimensions. Flanges may be purchased or made from sheet brass or copper 1/16" thick or heavier. While not absolutely necessary, some method must be used to mate the transducer to the horn. Solder the flange flush with the transducer.

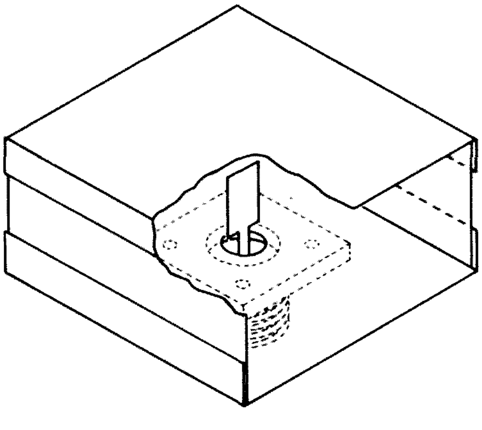

Fig. 3. Three-D drawing of the transducer.

The MTV Music Box

—Satellite Central, part VII

Part of the fun of TVRO experimenting is searching for new signals. While video is an easy mark, the real gold is sometimes harder to find, especially since new services keep popping up. The "video records" are a good example. Slide by transponder 11 on Satcom 3 (131 degrees west), and you'll find Music Television (MTV), a cable service from Warner Amex.

You may wonder why you are seeing rock groups blasting their brains out in near silence. It's because the audio portion of MTV is not on your typical TVRO receiver outputs of 6.8 or 6.2 MHz. Instead, different subcarrier frequencies were picked. Security? Perhaps.

Rock and roll music may not be your cup of tea, but the MTV delivery technique may become popular and worthy of more investigation since it is sent in stereo. And more important, you can experiment with a neat trick that mighty Warner never thought of!

Stereo Trickery

Just having two sound detectors to get stereo isn't enough. You need a decoder, too. Don't bother with a stereo FM-decoder setup because it won't work. MTV combines both channels, L+R, on one subcarrier and sends the difference between the channels, L−R, on the other subcarrier.

You can hear the sum channel on a 6.62-MHz subcarrier and the difference on 5.8 MHz. All you need to do is a little addition and subtraction with the electronics, and voilà...they separate into left and right! If you add the L+R signal to the L−R signal, the +R and the −R cancel, leaving just L, or 2L, if you want to be technical about it.

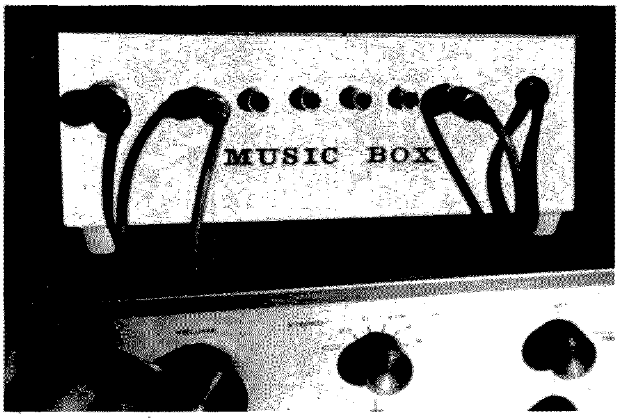

Photo A. Front view of the Music Box.

Likewise, if you subtract L+R from L−R, you get just 2R. The secret to all the addition and subtraction is a "matrix," which is a short and fancy way of saying two op amps from Radio Shack.

Before you rip the top off your receiver and start tweaking, you should consider an option. Why not build two more sound sections plus whatever else is necessary in a separate box, sparing your receiver? Don't worry if you are a Novice or your last project was an old tube-type Selecto-Jet. I've found an easy way for you to build this gadget.

Simple Circuit Details

The unit connects to your TVRO receiver at the same place your internal sound subcarrier-detector circuits tap off. Referring to Fig. 1, the detected composite video with audio subcarriers is coupled to two separate subcarrier sound detectors. One detector is tuned to

6.62 MHz and will give you an L + R output. The other detector is tuned to 5.8 MHz and delivers an L − R output. Each detector output feeds two op amps. I used a TL084 because it is cheap (available at Radio Shack) and works rather well. You get four amplifiers in a single chip. That sure beats the 6SN7 that some of you may remember.

A portion of the L + R detector output feeds the inverting input of the top op amp in the diagram. The L − R detector output feeds the non-inverting input. As in typical op amp fashion, its output is just the difference between the two inputs. So much for the subtraction part of the matrix. Addition is performed in the bottom op amp by summing the L + R and L − R detector outputs into the inverting input. Isolation is superb in this configuration because the inverting input is driven towards ground.

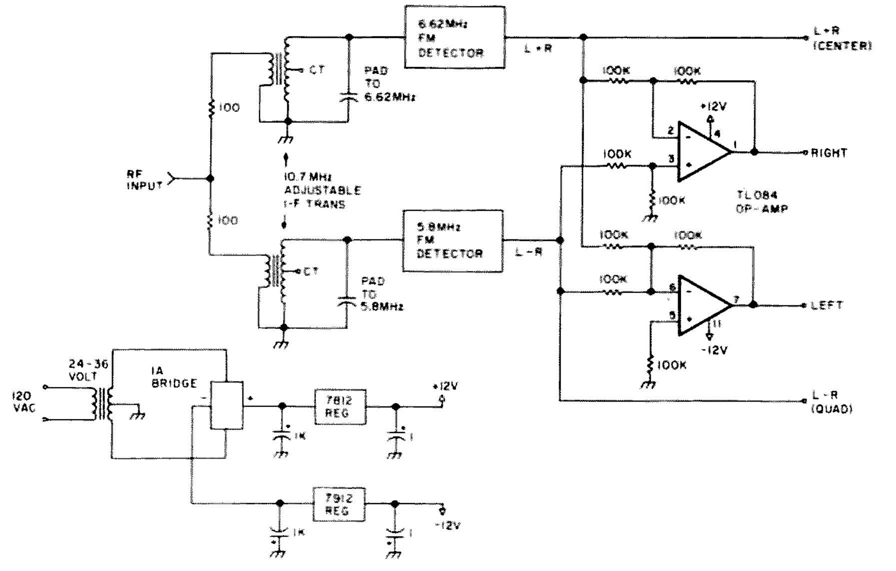

Fig. 1. Two PM-200 subcarrier detectors and a TL084 op amp are all you need to hear MTV satellite stereo.

An Evening Project

The subcarrier-decoder circuits in May's edition of "Satellite Central" will work very well. You can make a PC board for two detectors or use perf-type vectorboard and hand-wire the circuit in record time. Or you can even buy some dual-sound-section subcarrier PC boards from one of the *73* advertisers and just stuff 'n solder.

But if you are in a rush (and who isn't, nowadays) or if you are just learning about electronics, I suggest you take the lazy way and simply buy two RCA XL-100 sound-section modules like those described last month. Servicemen call them PM-200s. These little modules are complete TV-set sound sections and simply plug into the popular XL-100. Of course, they are tuned to 4.5 MHz (TV sound), but we can tweak them to the frequencies we want. In fact, we can modify them so that we get pretty hi-fi, too. Get two RCA MAA001As from a local RCA distributor. They run about 15 bucks each. You may be socked with a $3.00 dud charge.

Modification of the PM-200/MAA001A modules is very easy. We simply reduce the values of two capacitors so that we can tune higher than 4.5 MHz and then add two more capacitors to get better sound. Referring to Fig. 2, remove the T299 can and change C290 (82 pF) to 50 pF. Replace the can. Then change C295 (68 pF) to 25 pF. Now the unit tunes from 5.5 to nearly 8 MHz.

Next, solder a .01-μF capacitor from pin 13 on the CA3065 IC to a ground trace. This sets the de-emphasis to 75 μsec using a resistor inside the chip. Then solder a 5-μF (or so) capacitor from pin 8 on the CA3065 to a spare trace. If you don't see a spare trace, then cut the trace from pin 8 on the CA3065 leading out to the edge of the board and solder the cap across this trace cut. Just be sure the cap is polarized (end with + on it) towards the chip. Now you have a dc-blocked output to your amp. We don't use the preamp inside the chip because a quick look at the distortion specs would drive any audiophile back to AM radio!

Last, solder a 50k PC-type mini-pot from pin 6 on the chip to a ground trace. This is a volume control that we use in the mixing process. You can use larger shaft-type pots and mount them on the front panel, but they are likely to get bumped later on and will only reduce stereo separation. So why bother?

Depending on your TVRO receiver, you may need an input bandpass filter to cut noise from the video and adjacent audio subcarrier. The input coil (T299) works pretty well, but a cheap 10.7-MHz FM i-f transformer padded down to the proper

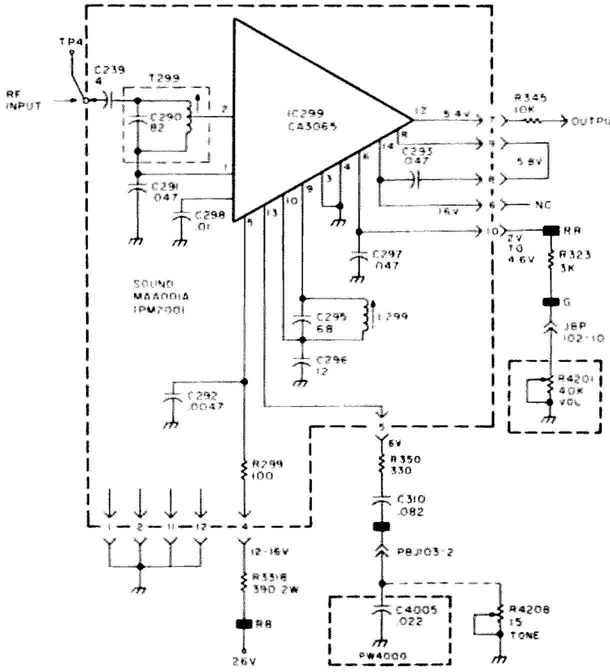

Fig. 2. The RCA PM-200 uses a CA3065 quadrature FM-detector IC for 4.5-MHz audio. The few mods discussed in the text will make it perform very well as a stereo sound decoder.

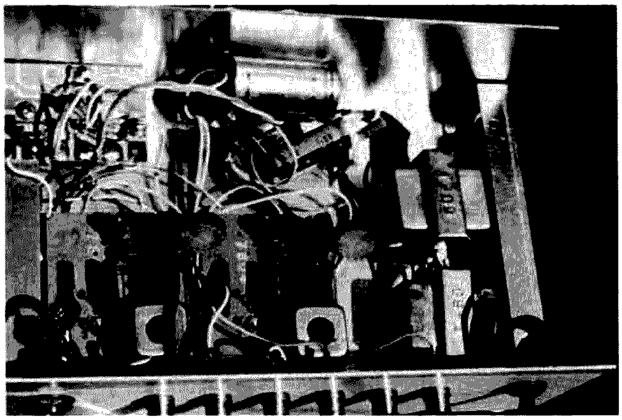

Photo B. Clean out that junk box with this project since nothing is critical. For example, two 12-18-volt transformers can be used instead of a single 24-36 volt. Even another op amp likely will work.

frequency knocks out what little noise is left. Not all transformers are the same, so a gdo or an rf generator will separate the winners from the losers. The secondary usually has a center tap.

Junk Box Jubilee

I decided to take a strictly plain-vanilla approach since I knew my little Music Box would soon be lost in the never-ending wire jumble behind my preamp. I used a utility box and mounted RCA jacks for all the outputs to my stereo system. (See Photo A.) The rf input was a lowly phone jack since I believe in using everything in the junk box. Use mini-coax if you have some. The input transformers can be soldered to the bottom of the PM-200s. The op amp was mounted on an experimenter's breadboard. All boards were mounted on standoffs. The PM-200 already has a hole in it for 6-32 hardware. Be sure to use voltage regulators to smooth the ripple. The op amps won't see ripple when running from a bipolar supply, but the little PM-200s want pure dc.

For the most part, construction is not critical other than the suggestion that you use coax to feed the PM-200s. Also, you should use 5%, ¼-Watt resistors in the op amp matrix (all 100k). While the pots on the detectors can be used to compensate for tolerances, we do want the tune-up process to be easy.

Next, you should modify your receiver. Find the location where the 6.2- and 6.8-MHz detectors connect. This is usually an emitter follower after video detection. Tap in with a dc-blocking capacitor. Then run more mini-coax to a BNC, type F, or RCA jack that you mount on the rear of the receiver. Take your choice. Use what you have. The signal is then patched to the Music Box with still more coax.

Tune-Up Hints

There are two ways to make the Music Box play. You can simply set both 50k pots for minimum resistance (that's maximum volume) and tweak the input transformers, the T299 coils, and L299 coils for sound. But knowing which subcarrier you are on may be a trick. Add to that the possibility that you may have both detectors tuned to the same carrier, and you're sure to see there must be a better way.

Use a signal generator set to 6.62 MHz. Feed it into the unit. Put a scope on pin 9 of the IC on the 6.62-MHz board (L+R) and tune the coils for maximum. Back the generator down below limiting and peak again. Do the same procedure for the other module (L−R), but set the generator to 5.8 MHz.

If the generator can be frequency-modulated by an internal oscillator, set it to ±75-KHz deviation and adjust the L299 coils on each module for the cleanest waveform. Depending on the particular run of PM-200s, you may need a resistor across L299 to lower its Q a small amount. A THD analyzer is a better eyeball if you have one. Without an analyzer, you are stuck with having to use your ear to fine-tune L299 for minimum noise and distortion.

While we're on the subject, don't expect the Music Box to play very well if your system has any sparklies. And narrowing the receiver i-f bandpass doesn't count, despite the picture improvement you'll likely see. It's what you'll hear that really counts. The first time a solid-color field is displayed (wider carrier deviation), you'll see and hear what many call frizzies, the bane of all "near threshold" systems. Even with music, nothing beats a good LNA and a large dish. Nothing.

At this point, you should be able to connect everything and hear pretty good stereo. Use headphones to verify. Some of the music is in mono, so don't worry if your first blast of sound is in the middle of your head. If you used 5% or better resistors on the op amps, you may be finished. Otherwise, the two 50k pots may need adjustment for maximum separation. Tweak either pot for best aural

WHY QUAD?

Back in the dark ages of stereo, David Hafler of Dynaco was experimenting with techniques to eliminate the so-called "hole in the middle" between left and right channel speakers—see Fig. 3(a). From that effort came a center-channel speaker which was simply the left and right channels combined (L + R) and played 6 dB softer. Then he went one better and suggested a single speaker *behind* the listener to add ambience. Logically, this ambience channel would consist of the difference between the channels, or L − R. Remember, we started with only two channels from tape or disk. This was revolutionary to audiophiles, but old hat to motion-picture people who'd been doing it for years with Cinemascope and 3D. (Funny how simple technology doesn't cross-pollinate now and then.)

Anyway, Michael Gerzon in England improved on the idea with the typical left- and right-front setup by feeding the difference (L − R) to separate speakers located at "left-rear" and "right-rear" and out of phase—see Fig. 3(b). It sounded so good that record people started recording ambience with a reverse matrix setup. Then they tried discrete channels, and you had technology go mad with the consumer wondering which system to choose. So much for history. Most stereo recordings have some ambience imbedded in them, so this technique is worth the extra effort to track down an old amplifier and two small speakers to fiddle with quadraphonics.

A 5th Channel?

If the front speakers are widely separated, you can connect a 5th channel to go between them. This will indeed reduce separation but tends to fill the "hole in the middle" effect. Cinema sound processors use this technique with an agc to restore apparent separation. Since a signal that would appear to be located at a point in space between the speakers would have to be coming from both the left and right channels, we must assume that it is the sum of the channels, or L + R—see Fig. 3(c). So feed another amp with the L + R output of the Music Box and place the speaker between left and right speakers.

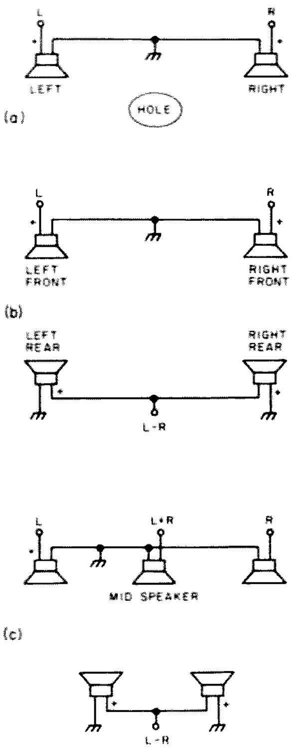

Fig. 3. Evolution of four- and five-channel sound. (a) Stereo, (b) quad, and (c) five-channel system.

separation or connect the Music Box outputs to the horizontal and vertical inputs of an oscilloscope. Without sweep, you can adjust the detector pots for a 45-degree angle trace on the CRT when mono is being transmitted. You'll see a "ball of yarn" display when stereo is being sent. Of course, you can always adjust for the most symmetrical jumble. What else would one do for rock and roll?

Next, connect the speakers. Watch phase because it is everything in a quad setup. If you are unsure, then first place a 1.5-volt cell momentarily across the voice coil of each speaker and note in which direction the cone moves. Mark the speaker lead with a + when the cell polarity causes the cone to move outward. All this is arbitrary, of course, but serves to give you a reference from which you can work.

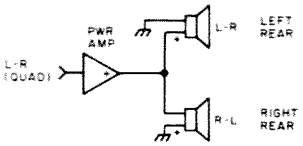

Fig. 4. Hookup for quadraphonic sound.

Music Box Bonus!

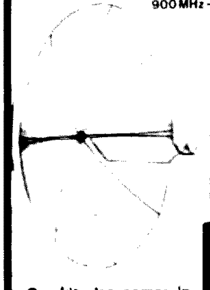
Sending the sound tracks in stereo was a pretty good idea. But what the Warner people didn't option was quadraphonic sound (at least until they read this)! And the little Music Box can do it. Quad sound? Yeah. . . and does it sound neat! And if four channels don't grab you, then how about five channels? It's just sitting up there on the bird waiting for you to snatch it!

For a quick trip into the history behind four- and five-channel sound, see the box. To get quad, just take the Music Box's L − R output, run it through a power amplifier, and connect two speakers as shown in Fig. 4.

Note that the speakers on the amplifier's output are connected in parallel but out of phase. The L − R goes on the left rear as you face the main speakers. The R − L goes on the right rear. Since the rear speakers will be radiating only ambience, you don't need to use the best that money can buy. Small bookshelf units work fine.

Setting levels for quad is a matter of taste. The ambience effect is very pronounced if the rear levels are high. But the stereo effect is reduced somewhat depending on the room. This is also true of the center channel. Too much level and separation goes away. As a rule, start your adjustments with the center and rear channels about 6 dB softer than the main left and right. And. . .oh yes. . .remember the threshold of pain is still +120 dB. But it may be less with rock and roll! ■

$54.95 **KD-44™**
Parabolic Reflector Kit
900MHz - 2.5GHz
25db



A low cost, high quality alternative to snow sleds and yagis. 44" diameter, 2 piece durable lightweight steel const. Includes feed-horn bracket, pre-cut hardware cloth and all hardware needed for assembly. Excellent for weather satellite and 1296 MHz experimenters!

Our kit also comes in a 2 ft. size with 19 db gain— ONLY $24.60

2300 MHZ CONVERTER KIT .... [illegible]
Includes PC board, parts & instruction manual

SELECTIVE PREAMP $39.95
For use with above converter. This preamp can also be used with other manufacturer's boards for improved performance

VARIABLE POWER SUPPLY .... [illegible]
Includes all components, case, overlays, and built in antenna switch.

DELUXE 2300 MHZ CONVERTER KIT .... [illegible]
Recommended for experienced kit builders. Dual-stage selective pre-amp, mixer, i.f. amplifier and no-drift crystal-controlled oscillator

13V STATIONARY POWER SUPPLY .... [illegible]
For use with Deluxe Converter

MODEL TMVS-1 KIT .... 55.00 Assembled 70.00
For use between two VCR's
MODEL TMVS-1RF KIT .... 79.00 Assembled 99.00
(Built in RF Modulator for direct connection from VCR to TV)

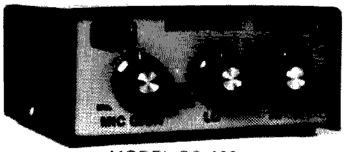
MICROPHONE EQUALIZER



MODEL EQ 200

Most signals contain excessive lows, very few highs that cause them to be muddy sounding, hard to copy, lacking articulation and prescence of sibilance (s & t sounds). These annoying conditions are NOT solved by audio processing. The answer is EQUALIZATION. Just as broadcasters and recording studios EQ their mic lines, the EQ 200 allows you to reduce distortion, add clearity, prescence and sibilance.

The card also has a Two Tone Generator circuit. By installing a few components, you can properly tune your SSB transmitter. Two Tone parts Kit $7.00

Tune In the World's Tinderbox

—SWLing from Cairo to Kuwait

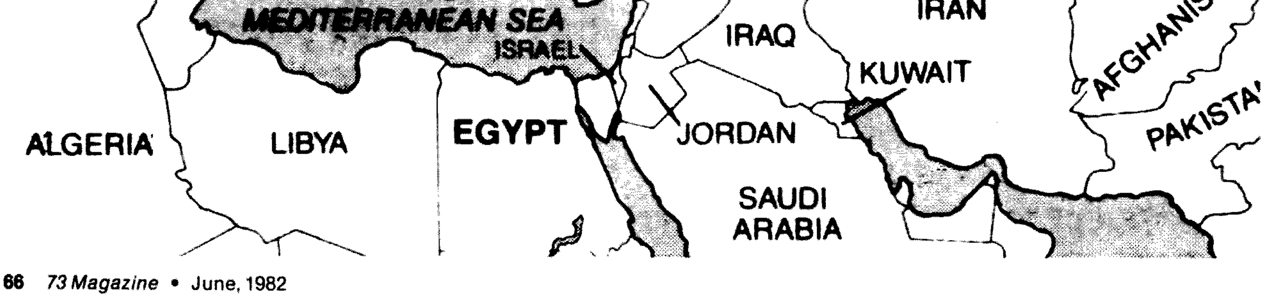
The assassination of Anwar Sadat, President of Egypt, was simply the latest, at that time, of a whole series of "incidents" in this conflict-torn area. The warfare between Israel and Egypt a few years ago, the fighting between Iraq and Iran, the invasion of Afghanistan by the USSR, and the ever-threatened stability of Saudi Arabia, Kuwait, and other Arab oil-producing states are all part of the turbulent Middle East scene. For a clear-cut, direct, day-by-day picture of this explosive part of the world, listen to your shortwave radio. All the countries mentioned above, plus others, have daily programs in English that can usually be heard well in North America. And you will find it interesting to compare the different viewpoints of these nations.

Radio Cairo from Egypt usually has a pretty good signal into North America. Its English programs can be heard at 2215-2345 GMT on 9805 kHz and at 0200-0330 GMT on 12.000 and 9.465 kHz. A 250-kW and a 100-kW transmitter are all the station has. Its programs always open with the sound of chimes (sounding suspiciously like Big Ben in London) and the words from a woman announcer: "This is Cairo, this is Cairo." Following this is a ten-minute news program. Then comes a regular pattern of music followed by a discussion of some timely topic, usually related to the Middle East. The music is Middle Eastern, reminiscent of Egyptian belly-dancing scenes in old movies. The music goes on for about ten minutes and then for 15 minutes you hear talk. Then back to the music, and so on. This is the regular daily program format. However, like the good broadcasters they are, Radio Cairo is not afraid to break out of the mold if the occasion calls for it.

If you had been listening to Radio Cairo on the evening that Sadat was killed, as I was, you would have been in for a most interesting experience. As soon as the official announcement of Sadat's death had been made, Radio Cairo discarded its regular format and put on a fascinating program about the late president. They covered his rise to fame and his accomplishments while president, and then switched to a report on the background of his successor, Hosni Mubarak.

To me, this was shortwave radio at its best. Such experiences give the listener the opportunity to go to the sources of major stories, wherever in the world they take place, and to get on-the-spot coverage that is usually way ahead of your local radio or TV news report.

Perhaps the most extensive broadcasting job in the



Middle East is done by Israel. Kol Israel, the voice of Israel's External Service, beams some six hours of English-language programs into North America, many of them very popular with regular listeners.

Broadcasting in Israel goes back to the days when the British ruled Palestine under a League of Nations mandate. They formed the Palestine Broadcasting Service (PBS) back in 1936 and put out programs in English, Hebrew, and Arabic. The present Kol Israel took its bow on the first day of Israel's independence, carrying Prime Minister David Ben-Gurion's original Declaration of Independence speech *live* on May 14, 1948, from the Tel Aviv Municipal Museum. The Hebrew broadcasting staff of the PBS joined up with those who had been broadcasting for the Jewish underground to form a nucleus for the original Kol Israel organization.

In 1965, a Broadcasting Authority Law was enacted that gave Kol Israel the same status that is enjoyed in Great Britain by the BBC. That is, it is administered by a Board of Governors acting as an independent body outside of direct government control. The executive head is the Director-General who is appointed by the government for a five-year term.

About two-thirds of the Israel Broadcasting Authority's budget is revenue from license fees of domestic listeners and TV viewers. The remainder comes from fees charged advertisers for commercials on domestic radio and TV. The External Service also gets direct grants from the government.

Kol Israel has a strong signal into North America with four 300-kW transmitters aimed at our shores. Broadcasts in English can be heard in the mornings, afternoons, and evenings. The last is the best time for reception, although afternoons generally also are good. Mornings at 1200-1230 GMT are usually not the best for reception.

In the evenings, listen from 0000 to 0030 GMT, 0100 to 0130 GMT, and 0200 to 0225 GMT on one of the following frequencies: 15.583 kHz, 11.640 kHz, or 9.815 kHz. Also listen from 0500 GMT to 0515 GMT on 15.105, 11.960, 11.638, or 9.815 kHz.

In the mornings at 1200, try for Kol Israel programs on 21.760, 21.495, or 17.612 kHz. Sometimes the reception at this hour is unusually good, but it is problematical, unlike the other times of broadcast.

From 2000 to 2030 GMT on 12.025, 11.960, 9.815, and 11.638 kHz, reception is usually strong. So, too, is it from 2230 to 2300 GMT on 11.960, 11.638, and 9.815 kHz.

All Kol Israel programs begin with a five-minute news summary and then go into their regular programming, which is different each day.

Sundays. "Calling All Listeners" is Radio Israel's popular DX program which gives up-to-date information on frequency changes for stations in the Middle East and also Kol Israel program details for the week. This program extends into Monday GMT times (0100, 0200, etc.).

Mondays. "Program Parade" gives forthcoming program details, and then comes "This Land," which is particularly aimed at people interested in touring Israel. Following this is "Spectrum," which reviews Israeli scientific developments.

Tuesday. "Israel Mosaic" gives the listener interesting facts about life in that country. "Pop Sound" offers music, and then comes "Personally Speaking," a program with guest commentators.

Wednesdays. "Israel Forum" is the big program of the day and offers the listener some lively discussions about people and politics.

Thursdays. "Time Out" offers interesting feature stories about life in Israel.

Fridays. "Music from Israel."

Saturdays. "Israel This Week" is a review of current events of the past six days.

Compared to Israel, the other Middle East broadcasters are, for the most part, inferior. While some have good signals, they are not on the air very much and their programming is, by comparison to Kol Israel, somewhat crude. However, if you are not listening just for enjoyment, as you might with the BBC or other Western stations, but to get information and various viewpoints, these other Middle East stations do give you that.

Radio Kuwait is an interesting station to listen to. This little country—about the size of Israel but with only half as many people—has some 15% of the world's oil reserves. Oil pays for just about everything there—free medical care, education, and social security. Best of all, there are no taxes!

Kuwait, as might be expected, has modern Western technology working for it, and this includes shortwave transmitters in which there are four 250-kW and two 500-kw units. They have a pretty good signal into the US from 1800 to 2100 GMT every day. They use only one frequency—11.675 kHz—but the equipment is good enough to make this almost always a good one for receivers here in this country.

A typical program from Kuwait goes like this:

—1800 GMT—Station Identification; music (Arab style);

—1830 GMT—15-minute talk on some current event in the Middle East by young lady;

—1845 GMT—More music;

—1900 GMT—Western-style music;

—1930 GMT—Review of the week;

—2000 GMT—Music (Arabic); and

—2030 GMT—Discussion of economics by a man.

Listening to Radio Kuwait is similar to sticking with Radio Cairo. It's not easy to stay glued to the receiver on stations like these unless something special is happening in the area. This, of course, is very likely these

days, with the Middle East set to have an explosion of some kind at any time. Thus, it makes sense to know where to find stations like Radio Kuwait on your dial and to check into them from time to time.

A real disappointment is Saudi Arabia. Here is one of the largest Middle East countries, with a population of 9,290,000 and geographically a quarter the size of the US. Like Kuwait, it is oil-rich. Unlike Kuwait, which has a literacy rate of over 60%, Saudi Arabia has a rate of only 15%.

The Saudis have three shortwave transmitters—a 50-, a 100-, and a 350-kW. They should spend a couple of bucks and buy more or better ones. Reception is not very good here in the US. They broadcast from 1800-2100 GMT on 11.856 or 7.210 kHz.

When you do tune them in, the program starts with a man saying, "This is Radio Jeddah, the broadcasting service of the Kingdom of Saudi Arabia." The program that follows is a mixture of Middle Eastern music and talk, the latter primarily explaining positions on oil prices, purchases of modern arms from the US, etc. Again, while not the most entertaining station to listen to, it could be of great interest should some event take place in that part of the world.

A much more intriguing station to listen to is UAE Radio in Dubai, in the United Arab Emirates. Here is a little country that I had never heard of before becoming a shortwave radio listener. It has a population of less than a million people and is roughly the size of Maine. However, oil revenues give the UAE one of the highest per capita gross national products in the world. This little country was a British protectorate until 1971—another reason for its obscurity.

From a broadcasting standpoint, UAE Radio is a pleasant surprise. It has three 300-kW transmitters which seem to reach us here in North America extremely well. Its English programs can be heard twice daily, at 0330-0357 GMT on 17.775 and 9.590 kHz, and from 1610-1650 GMT on 21.695 and 17.710 kHz.

After station identification by a young lady who sounds as though she has been educated in London, England, UAE Radio offers not the news, as is the usual shortwave broadcasting technique, but a feature story. Recently, for example, it had an interesting 15-minute talk on the history of the trade of that geographical area with China during the time of the Crusades. Following this came ten minutes of music—not Arabic music, but the kind we hear on US FM "beautiful music" stations. After this came the news.

News is done in BBC style. That is, first they give you the headlines, then the detailed stories, and then a repeat of the headlines. You can see the British influence in their broadcasting. With the exception of Israel, UAE Radio appears to be the most westernized of all the Middle East stations.

Another pleasant surprise in Middle East stations is Radio Baghdad from Iraq. This station also has very good programs, and even though it is reported to have only a single 250-kW transmitter, it comes in with a pretty strong signal to North America. A typical program starts with 15 minutes of news followed by about five minutes of music (Arab style). Next comes a five-minute editorial (perhaps on the war with Iran and why they are fighting), followed by more music. Then another talk and more music.

While it may sound rather boring, the fact of the matter is that the talks are well thought out and very well delivered. It is good listening if you are at all interested in what is going on in the Middle East.

Iraq is not a large country (a little bigger than California in size and with a population of 12,000,000), but it is one of the key nations in the area and, unlike some, has a pretty good record for stability. In other words, its attitudes and thinking will be important in future developments in the Middle East. You can hear Radio Baghdad every day at 2130-2225 GMT on 9.745 kHz and at 0300-0335 on 21.585 kHz.

The other countries in the area are an "iffy" proposition as far as reception is concerned. Iran, three times the size of Iraq in both population and area, can often be heard at 1930-2030 GMT on 9.022 kHz. Programs are not exactly award winners, but you do get the Iranian point of view.

Afghanistan can usually be heard at 1900-1930 GMT on 15.077—but not very well. Algeria can sometimes be heard at 2100-2130 GMT on 25.700 or 15.215 kHz. Some listeners have heard Lebanon on 11.790 or 11.860 kHz at 0230-0300 GMT. DXers have caught additional Middle East countries, but not with programs in English.

However, for those of you who want to keep up with what is going on in that part of the world, you have a pretty wide choice of stations with good signals and fairly good programs—Israel, Egypt, UAE Radio, Kuwait, and Iraq. This assortment gives you a good balance of opinions. After a few months of listening to this array of programs, you'll be the best-informed guy or girl on the block about the Middle East. ■

Are You Ready for 900 MHz?

This article is based on a paper given at the 27th Annual VHF Conference, Western Michigan University, Oct. 17, 1981, Kalamazoo MI.

Since the proposal and decision to allocate the 902-928-MHz segment of the UHF spectrum to the Amateur Service,[1] VHF/UHF enthusiasts and experimenters have wondered how best to utilize this new resource and what equipment would be needed to communicate efficiently on it. This article will address those topics and will propose a band plan for the amateur community based on experience with other VHF/UHF bands and proven radio-frequency design techniques.

History

Recent use of the frequency spectrum from 902-928 MHz in the United States has been for radio-frequency heating, i.e., the Industrial, Scientific and Medical (ISM) service. Early commercial and consumer microwave ovens used this wavelength, although most now have changed to 2450 MHz for improved performance at this higher frequency.[2] Most ISM heating devices (typically magnetrons) are tuned to a center frequency of 915 MHz and, with their pulsed power operation, generate considerable amounts of energy in the form of sidebands. Thus, guard bands of plus and minus 13 megahertz about the center frequency were adopted to minimize interference with services in immediately adjacent allocations.

Warning: The 915-MHz frequency was originally chosen for its heating effects on substances with high water content such as food and, unfortunately, human flesh!

The ISM service will share the new amateur allocation on a secondary, noninterference basis as the proposals now stand. Both services will share the band with Government Radiolocation (radar), which will have primary status (this is the case in many UHF/microwave amateur bands). In addition, other restrictions provide that the new band will not be available to the Amateur Satellite Service and that it may be susceptible to interference by Automatic Vehicle Monitoring (AVM) systems pending consideration by the Federal Communications Commission.[3]

Propagation

The new UHF allocation has shown in commercial land mobile tests that it behaves much as expected—attenuation by natural objects such as trees and earth will be greater than on 450 MHz, necessitating increased effective radiated power. However, in urban areas, because of the much shorter wavelength, its specular reflection allows much better coverage in areas forested by tall buildings and tunnel structures.[4]

Much research has already been accomplished by the commercial community in its quest to proliferate the cellular mobile radiotelephone services into the 825-to-890-MHz area. Several excellent articles have appeared documenting extensive tests that have been performed in a variety of areas (mostly metropolitan) around the United States.[5,6,7] The operational characteristics of amateur mobile FM voice should parallel these results quite closely.

One area of concern in using the new 33-centimeter band for mobile communication is the rate of signal cancellation and addition (mobile flutter). At two meters, the same phenomenon that causes lost words during transmissions will, at 900 MHz, add a low-frequency buzz to demodulated audio. At speeds of 30 to 60 miles per hour, the frequency of this tone will be approximately 80 to 160 Hz for a transmission frequency of 915 MHz. Although this is not a problem for voice intelligibility (it can be filtered out by appropriate audio high-pass filtering), it does cause the present continuous tone subaudible squelch (CTSS), known more popularly by its trade name, Private Line,[8] to malfunction by unsquelching a receiver when there is actually no transmitted CTSS tone. Thus, different selective-signaling methods, perhaps tone burst or digital squelch composed of a short duration serial-bit stream at the beginning of each transmission, would be required for reliable operation.

902.0 MHz—CW/SSB
902.6 MHz—FM voice/RPT
(mobile receive, RPT transmit)
906.0 MHz—ATV Channel A
912.0 MHz—ATV Channel B
918.0 MHz—ATV Channel C
924.0 MHz—FM voice/RPT
(mobile transmit, RPT receive)
927.4 MHz,
928.0 MHz—Control Links, Packet Transmissions

The band plan proposed by WB4LNM in October, 1981, for 902-928 MHz.

Hardware

Equipment for communicating at 900 MHz is another area where the commercial communications services are helping almost as much as when they dumped thousands of old VHF high-band transceivers on the amateur market in the late 1960s. Although it will be many years before the new cellular radios will be available as surplus, the components and technology used in these transceivers will be produced in mass quantities for the many tens of thousands of

mobile radiotelephone users that are expected to populate the adjacent commercial band in the next few years. Several semiconductor manufacturers already are producing components that will work well in amateur transceivers.[9,10,11]

For those who don't want to build down to the basics, there are also hybrid power-amplifier modules that require little more than application of proper drive signals, power-supply voltages, and heat sinking.[12] These would be suitable for FM, PM, or CW operations, and require only 250 milliwatts of input energy for 7.5 or 20 Watts output.

Receiver designs will be of the same general superheterodyne style we are accustomed to, but with significant differences in the construction of the rf amplifier and first mixer stages. To enhance selectivity, small cavity resonators or helical resonators will be used for their low-loss characteristics and their physical size, which will reach manageable proportions at this wavelength. Gallium arsenide field-effect transistors, once expensive devices for commercial and military systems, will be employed to minimize noise figures when used ahead of Schottky diode double-balanced mixers known for their inherent excellent wide dynamic range. The cost of these mixers continues to decrease as they are used in more and more communication systems. Several manufacturers already offer, in small quantities, preassembled mixer modules that work to 1 GHz for under ten dollars.

Building at 900 MHz will introduce the newcomer to a different attitude toward the components he uses. The rules here are, "the only good leads are no leads," and, "it may look like a capacitor to you but what does it look like to the circuit?" At this frequency, a one-eighth-inch lead of #22 AWG wire on a 270-picofarad disc capacitor exhibits an inductive reactance larger than the capacitive reactance of the capacitor. Thus, the capacitor at this frequency is actually acting as an inductor.

Chip capacitors, capacitors with no leads at all, are frequently used where this effect becomes a problem. Although they are reasonably expensive, their price can be expected to decrease since the production process for manufacturing them is automated and they are now being used in the computer industry to help digital devices comply with stringent new radio frequency interference regulations.

One of the toughest problems to tackle will be that of frequency stability, especially in mobile and portable equipment. Consider a typical transmitter crystal of frequency 33.4074 MHz (902 MHz divided by 27), with a tolerance of 0.001% over the extremes of temperature, shock, and voltage. This crystal could exhibit a drift of 9 kHz at 902 MHz and still be within specification. If the new amateur band were to follow the normal 25-kHz channel spacing and 13-kHz occupied bandwidth used on 450 MHz, it is obvious that the communications system would suffer great degradation in both adjacent channel selectivity and demodulation distortion if this crystal were used.

Several ingenious ideas have been proposed to alleviate this stability problem, or at least to transfer the problem to a station capable of maintaining an accurate frequency standard.[13] If the mobile transmitters were designed to operate in full duplex mode, the signal received from the repeater (assumed to be stable and accurate) could be used as a reference to which the mobile transmitter could be frequency-locked. Since the vast majority of vehicular operation on this band will most certainly be tied to repeater systems, this method represents a very cost-effective solution. The band plan suggested later in this article was developed with this concept in mind.

Another positive aspect of a full duplex system is that it will allow the operator to gain immediate knowledge of how well he is communicating with the retransmission site, because he will be able to listen to his own signal as it is retransmitted (perhaps at reduced volume in the receiver to prevent audio feedback).

Antennas for the 33-cm band will be small enough to be built easily with simple hand tools and mounted on masts no larger than small television antennas. A fourteen-element parasitic yagi-uda array, which magnifies a transmitter's power 16 times, occupies a space of only 6.5 by 28.5 inches. Corner reflectors, which have never been widely used by amateurs at lower frequencies, are easily constructed and offer a decent amount of gain and fairly wide bandwidth. Of course, for those who can afford the price (and have no neighbors), a four-meter diameter parabolic dish gives about 27 dB gain and can be used on the higher microwave bands as well.

Using It

Many different ideas, amateur conventions, and technological factors were considered when attempting to formulate a band plan that would serve all the needs of the amateur fraternity. The following plan is the distillate of those components.

One aspect of the hobby that appears to be in a growth mode is that of fast-scan television and computer-generated video. On the 70-centimeter band, the wide, buzzing video carriers are not well received (more accurately, not welcome) near the weak-signal satellite downlink subband from 435-438 MHz. This has prompted ATV, in several metropolitan areas of the country, to move to 23 cm in search of usable spectrum. However, the expected allocation of 1260-1270 MHz to the amateur satellite service,[1] coupled with the recent removal of amateur operating privileges from 1215 to 1240 MHz for military navigational satellite systems (NAVSTAR, GPSS),[3] as well as the difficulty of generating healthy amounts of power at 23 cm, makes this band less than desirable for fast-scan television.

I am proposing, therefore, that three 6-MHz-wide standard video channels (with multiplexed FM voice if desired) be centered in the proposed band plan. Since these three channels would be broadcast standard video format and frequency spacing, only one local oscillator per downconverter would be needed to mix all three down to contiguous VHF or UHF broadcast channels for display on a standard unmodified television receiver.

For the FM crowd, the band plan proposes 128 new FM channel pairs spaced at 25 kHz, with the transmission and reception frequency difference (split) at 21.4 MHz. This would allow use of relatively inexpensive monolithic crystal filters at an intermediate frequency of 21.4 MHz and the frequency-locking of transmitters to received pilot carriers from repeaters. Although this is an extremely low first i-f for a radio of this type, a judicious mix of image-cancelling mixer technology and low-loss

front-end filtering will provide good image rejection and sensitivity.

The portable equipment receive band is placed at the low end of the new spectrum, causing the image frequencies to be thrown into the avionics (DME, TACAN) band instead of the new cellular radiotelephone band. Since the smaller mobile transceivers have less room for cavity filters, that can be implemented more easily in fixed-retransmission sites. The ATV repeater-output spectrum is also located at the same end of the band as the FM voice repeater so that the two types of repeaters can be easily co-located. Point-to-point service for low-band repeater linking, packet-transmission techniques, and radio-command systems would be placed at the high end of the band.

Space has been reserved at the lower end of the band for weak-signal modes, SSB, and CW, as is common on the lower VHF and UHF bands. This 600-kHz swath allows for many 3-kHz sideband voice channels for tropospheric-scatter, moonbounce, and meteor-scatter experiments. Initial experiments may be carried out with little more than a returned 451-451.30-MHz commercial FM transceiver driving a varactor doubler for CW transmission. From past experience with both listening and operating on the other bands above 30 MHz, this will provide plenty of weak-signal spectrum space for the foreseeable future.

Conclusion

Techniques and equipment for the new amateur band from 902-928 MHz have been discussed. A band plan which tries to serve all users in the amateur community has been proposed. Particular emphasis has been placed on the need for fast-scan television transmission spectrum since it appears that ATV mode has been nudged out of other regions of the amateur spectrum. It is hoped that the discussion of the new UHF band will entice you to build or buy equipment and operate this frequency range no matter what your special interest is. With 26 MHz of spectrum, there is room for everybody! ■

TERMINALL

apple* + TRS-80*

TERMINALL is a hardware and software system that converts your personal computer into a state of the art communications terminal. Terminall features simple connections to your computer and radio plus sophisticated and reliable software.

Simplicity

TERMINALL was designed from the outset to be easy to connect to your radio and easy to use. Plug into your receiver headphone jack and copy Morse Code or radioteletype (RTTY). Plug into your CW key jack and send Morse Code. Attach a microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.

The software is loaded into your computer from disk or cassette. Enter your callsign and the time and you will start receiving immediately. No settings or adjustments are necessary to receive Morse Code, it's fully automatic -and it works! You may type your message while receiving or transmitting.

You will be on the air, receiving and transmitting in any mode, in minutes. As we said, TERMINALL is simple.

More for your money.

■ TERMINALL has the RTTY terminal unit - demod and AFSK -built in. This results in a lower total cost.

■ **Fantastic Morse reception.** Six stage active filter demodulator copies the weak ones. Auto adaptive Morse algorithm copies the sloppy ones. Received code speed displayed on status line.

■ **Outstanding documentation.** Professionally written, 90 page user manual contains step-by-step instructions.

■ **Built in, separate, multi-stage, active filter RTTY and CW demodulators.** No phase lock loops. RTTY demodulator has 170 and either 425 or 850 Hz shift-keyboard selectable - and uses either the panel meter or scope outputs for easy tuning. Copy the weak ones. Copy the noisy ones. Copy the fading ones.

■ **Built in crystal controlled AFSK.** Rock stable for even the most demanding VHF or HF applications. A must on many VHF RTTY repeaters.

■ **Built in 110 or 220** volt AC power supply.

■ **Built in parallel printer driver software.** Simply attach a parallel ASCII printer (e.g. the EPSON MX-80) to your printer port to obtain hardcopy in all modes.

■ **Multi level displays** - allows examining and editing of historical text.

■ **Word wrapping**, word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, multiple user-defined WRU, transmit delay (fixed, none or auto adaptive), break mode and more!

■ **The all-in-one TERMINALL design** makes it great for use on HF or VHF, Ham, Commercial, SWL or MARS! SWL's: TERMINALL may be jumpered for either 425 or 850 Hz reception to copy news and weather services.

System Requirements

TERMINALL T1 Communications terminal for the TRS-80 Model I. Requires a Model I TRS-80, 16K RAM and Level II BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T3 Communications terminal for the TRS-80 Model III. Requires a Model III TRS-80, 16K RAM and Model III BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T2 Communications terminal for the APPLE II. Requires an APPLE II or APPLE II PLus with 48K RAM and disk. Software is provided on disk in DOS 3.2 format, use MUFFIN utility to convert to DOS 3.3 format. Includes software on disk, assembled and tested hardware and an extensive instruction manual. **$499.**

Crime-Stoppers' Textbook

—rules of thumb for would-be gumshoes

Robert C. Diefenbach
2402 Lauderdale Drive, NE
Atlanta GA 30345

No one seemed to notice the tan car that stopped at the quiet corner only long enough to drop off a tall, casually dressed young man. As the car drove unhurriedly away, the young man began walking past the neatly trimmed yards looking—carefully looking—at each house as he passed. No one seemed to notice.

But the driver of the car with amateur radio tags did notice, and a few minutes later also noticed the same tan car stopped in the shade of a clump of low pine trees in a nearby church parking lot. The car's hood was raised. Its driver, standing in front with one foot resting on the bumper, was making some unseen adjustment to the idling engine. He appeared impatient as he glanced at his wristwatch.

B.M. Gray II.

Driving past the parking lot, the ham noted the dented left front fender on the tan car and the driver's blonde hair and blue football-style jersey. And more. By the time he pulled his car to an easy stop midway down the next block and reached for the microphone clipped to the dashboard, he knew exactly what he would say to the police dispatcher.

It took only moments to place the call through the repeater phone patch.

The dispatcher's voice was crisp. "Police emergency."

"I want to report a suspicious car and persons on Thomason Drive. I suspect they are planning a burglary."

"Stand by."

There was nothing remarkable about this series of transmissions or others like it, heard infrequently on the amateur and business radio bands, except that they are heard *very* infrequently in proportion to the potential criminal activities witnessed by drivers of radio-equipped vehicles. Law-enforcement agencies wish fervently that there were more civilian radio exchanges like this one. They need all the help they can get.

There are only 2.1 full-time law-enforcement officers per 1000 US citizens, according to the latest figures released by the Federal Bureau of Investigation. These men and women do their best in the face of an alarming increase in serious crime, but they are, as a group, vastly overworked. Since 1971, property crimes (burglary, larceny-theft, and motor-vehicle theft) have shot up 54 percent nationally. Violent crimes (murder, forcible rape, and aggravated assault) have risen 60 percent. In just one year, from 1979 to 1980, burglaries and robberies rose 14 and 18 percent, respectively.

As federal, state, and local governments tighten their belts in the current wave of budget and tax revisions, there is not likely to be much—if any—increase in the number of professional crime fighters in most jurisdictions. There is a clear and growing need for appropriately-controlled civilian involvement.

Special Agent Edward J. Tully of the FBI points out that "there has been a tendency for civilians to forget their responsibility for effective law enforcement. Clearly, police departments cannot do the job alone." Tully is acting academic dean of the FBI Institute in Quantico, Virginia, where police officers from cities of all sizes are trained alongside federal and state agents and policemen and -women. "Citizens with access to mobile two-way

radios, or ham radio opertors, can be of significant assistance," he said.

Sanford H. Smith, a leading national figure in public-safety communications, agrees wholeheartedly. "The present trend in our country is towards self-help. Increased citizen involvement in law enforcement is a natural part of that trend." Mr. Smith is Director of Communications for the city of Greensboro, North Carolina, president of the Land Mobile Communications Council, and immediate past-president of the Associated Public Safety Communications Officers, Inc. "When we feel we have done something for our community and our fellow men, there is a huge personal reward," he adds.

When the FBI and any other law-enforcement agency solicit civilian help, they are definitely not suggesting that the civilians "play policeman." That is the very last thing authorities want and is probably the best way a civilian could pick to become a part of the *problem* instead of the *solution*! What is wanted and needed is responsible, reliable observation and reporting of potential or actual criminal activities, and NOT vigilantism or other unauthorized direct involvement.

Professionals in law-enforcement communications—"sworn" officers and civilians alike—agree that radio-equipped volunteer observers' reports are valuable. They stress that these reports are more valuable when the observers have been trained, even minimally, by their local police departments.

The concept is endorsed by The Crime Prevention Coalition, a group of almost 50 prestigious national organizations whose combined efforts are behind the multimillion dollar "Take a Bite Out of Crime" advertising campaign. B.M. Gray II, Director of Crime Prevention, says, "Surveillance by drivers of two-way radio-equipped vehicles could be one of the most useful citizen involvements in preventing crimes, particularly street crimes, from occurring. Drivers whose radios give them the ability to notify and communicate with the police without leaving their vehicles—whether amateur radio hobbyists or commercial drivers—can be a definite asset."

Why the need for training? It sounds simple enough: If you see something unusual or suspicious, call the police. That's the basic idea, all right. But when *is* something unusual or suspicious? *What* should be reported. *How* should it be reported? Police-directed training is the most reliable source for answers specific to each community's needs and resources.

Most police departments are anxious to work with local citizens who express interest in helping them. A letter to the office of the Chief of Police, volunteering to help and asking to be trained, is a good way to start. You might attach a copy of this article as a way of introducing the subject.

The amount of training police departments can provide—from informal advice through classroom presentations—varies widely, depending upon the resources available. Understandably, most departments will devote more attention to training requests that represent bigger potential payoffs—larger numbers of reliable radio-equipped observers on the streets. Several ham radio clubs or repeater groups, or the owners of several smaller firms which operate radio-equipped vehicles, can effectively combine their initial contacts with the police.

Sanford H. Smith.

What Is Unusual or Suspicious?

Deciding what is unusual or suspicious enough to report to the police calls for subjective, case-by-case judgment. It is easy to err in either direction: reporting inconsequential observations or failing to report meaningful ones. Detective Jerry Jaquenta KA4NIA of the Boca Raton, Florida, Police Department burglary squad, voices the opinion of most law-enforcement professionals. "We would far rather get a dozen or more false alarms—calls reporting what turn out to be entirely innocent events—than risk missing the one call that does involve crime. If there is reasonable doubt, *call!*"

Detective Jaquenta lists these examples among observations he thinks should be reported: persons—such as obviously truant students—who are obviously out of place where they are observed, perhaps with a screwdriver or gloves sticking out of a pocket, someone knocking at the front door and moving to the rear of a house when there is no answer, and occupied cars or trucks parked in concealment.

"But don't be guided only by a person's appearance," cautions Sanford Smith. "It is a subject's *actions* that will usually tip off a good observer." Persons who seem to be hiding, or showing nervousness while loitering, are high on Smith's list of significant observations.

"Any sort of violence should be reported quickly," adds David N. Wise N8CNY, veteran chief of the Michigan State Police Department's twenty-

David N. Wise N8CNY.

seven communications dispatching locations. "Whether it is as obviously criminal as a robbery or only potentially so—as in a street-corner shoving match that looks as if it could become a fistfight—let the police know. But," he emphasizes, "do it from a safe distance!" Exposing yourself to danger or violating the law yourself—for example, following a speeding car—isn't just foolhardy. It is dumb!

Police dispatchers, particularly in smaller jurisdictions, soon learn whether regular callers are reliable observers or merely busybodies. If you remember the old tale about crying wolf, you will agree that it is best not to get the latter reputation.

What Should Be Reported?

Public-safety communications expert Sanford Smith lists these four components of an observation report, in the order in which they should be given to a police dispatcher.

- *What is being reported?* Tell the dispatcher immediately. A robbery in progress? A suspicious person or vehicle? An accident? A fire? A potential suicide? Knowing what the basic problem is, the dispatcher can decide what public-safety resources may be needed. Radio operators should know that most police departments would rather get several radio reports of a serious traffic accident than not receive any because each passing radio-equipped observer assumed someone else had reported it.
- *Where is it happening?* Give as accurate a location as possible. Include street names, nearby intersections, building numbers, and easily-recognized landmarks.
- *Who and where are you?* The radio or telephone link between you and the police could somehow be broken. Give the police dispatcher your name, exact location, and a way that he or she can get back in touch with you if you are disconnected. This is especially important in bigger cities where several dispatchers are on duty at a time. Calling back after disconnecting, you may get another dispatcher and have to start your report all over again.

Ham radio operators, and others who can talk to the police directly through repeater phone-patch facilities, are not so easily recontacted if the patch times out or the connection breaks some other way. Hams should ask for help from another amateur monitoring the frequency from a location with a telephone, and that telephone number should be given to the police dispatcher. If no one else is on frequency, think of some other way the communications link might be re-established if it breaks. Be sure that you and the police department both understand how the recontact will be made.

If the report is being made through a taxi, delivery service, or other business radio dispatcher, that business dispatcher's phone number should be given to the police dispatcher.

Some law-enforcement agencies will insist on recording your identity—as much to discourage anonymous nuisance calls as to add to their record. Others will ask your name, but treat your report with equal seriousness whether you give it or not. While some radio operators may shrink from getting involved in an incident they observe by identifying themselves, they should realize that by giving their names they are assuring the police that they believe in the accuracy of their report.

- *What are the details?* Your eyes may fool you. Simply being able to see all of the details that occur during an exciting, stressful event can be difficult. Under these circumstances we are all subject to a physical phenomenon called tunnel vision. As we concentrate intently on what is going on in the center of our visual field, we actually lose a great percentage of our peripheral—or side—vision. Being aware that this may happen to you will help you prepare to overcome tunnel vision by making a conscious effort to look *around* the central action for important details.

When describing persons, follow this standard sequence. Leave out any item you do not know.

1. Name
2. Sex
3. Race
4. Age
5. Height
6. Weight
7. Hair
8. Eyes
9. Complexion
10. Physical characteristics: marks, scars, limp, etc.
11. Clothing, from head to foot: hat, shirt, coat, trousers, socks, shoes.

When describing vehicles, start with the color or colors, then give the make, model, and as many give-away markings—accessories, damage, etc.—as you can. The license number or any part of the number can be very helpful to the police. But stolen tags are commonly used by criminals, so an accurate description of the vehicle itself is just as important.

How Should It Be Reported?

To be useful, reports must be made calmly, clearly, and objectively. That may not seem too difficult when you are describ-

Legal Issues In Civilian Surveillance

Does a radio operator step onto dangerous legal ground by making reports to the police? Can he or she be sued for slander? For false arrest? Not if the reports are *accurate*, according to Lewis J. Paper, former Associate Counsel of the Federal Communications Commission, now in private practice in Washington, DC. "It would be difficult," he says, "to conceive a situation where simply reporting—*accurately* reporting—what is observed could expose the observer to any liability."

Attorney Paper recommends that as soon as possible after making any direct or indirect verbal report to the police, radio-equipped observers should make a personal written record of everything seen and said concerning the event, and then save the record. If made while memory is still fresh, this document can be very helpful later if you are ever called as a witness in any court action that ensues. You can be subpoenaed by either the prosecution or defense. Your record itself will probably never be called into evidence. But if there is—and there frequently is—a long delay between the event and a trial, it will protect you against a lessening or loss of memory that could occur before you are asked to testify.

"Although most states' slander laws vary in detail," says Mr. Paper, "generally a charge of slander must be based on reporting information which the reporter *knows or should have known* was false. A written record—by its very existence—will help minimize any risk that you will be accused of intentionally lying."

Provided you have accurately reported your observations, according to Mr. Paper, you have no liability if the police are charged with false arrest after detaining someone as a result of your report. "In making the arrest the law-enforcement agency assumes the responsibility and any liability for that arrest," he says.

Like every other authority contacted in connection with this article, Mr. Paper quickly and firmly points out that volunteers must remember that they can expose themselves to liability for violations like trespass and assault by acting as if they have powers which, *without specific legal authority*, they don't have! ■

Detective Jerry Jaquenta KA4NIA

ing a minor auto accident on the freeway. But it *is* difficult when actual crime or violence is concerned. Even police officers have had difficulty making proper radio transmissions under emotionally stressful circumstances. Here are some tips from the experts:

- Think about what you are going to say before you transmit. Even if it means a short delay, compose your message mentally to be sure it is accurate, concise, and in the sequence that will be the most helpful to the police dispatcher.
- Keep your transmissions short. Break frequently to allow the person on the other end to interrupt.
- Control your voice. When excited or upset, many people tend to speak faster and to raise the volume and pitch of their voices. The combination makes for hard-to-copy radio transmissions. Listen to yourself. Keep your voice as close to normal as possible.
- Avoid subjective words. Be specific in describing what you see. The dispatcher doesn't know what you think "a bad fight" is or what "a whole bunch" of injured motorists means.
- Speak plain English! Leave the "ten-this" and "ten-that" and other supposed-to-be police jargon to the TV heros. The few seconds you think you might save by using jargon is not worth the risk of being misunderstood.
- Stay at your radio. Except to render whatever aid you can to an injured person, you can be more helpful by being keeping a communications line open between the police and whatever action you are observing.

Don't forget the important don'ts: *Don't* expose yourself to danger! *Don't* play cop! In the process of trying to assist the police, *don't* violate any laws yourself. ■

MOR-GAIN

1/2-size (75M only 66')

Multi-Band (5, 4, 3 bands)
80/75M thru 10M

Broadbanded - no traps used

Prices start at $82.50

MOR-GAIN

THE MOR-GAIN HD DIPOLES are the most advanced, highest performance multi-band HF dipole antennas available. Patented design provides length one-half of conventional dipoles. 50 ohm feed on all bands, no tuner or balun required. Can be installed as inverted VEE. Thousands in use worldwide. 22 models available including two models engineered for optimum performance for the novice bands. The Mor-Gain HD dipoles N/T series are the only commercial antennas specifically designed to meet the operational requirements of the novice license. Our 1-year warranty is backed by nearly 20 years of HD dipole production experience.

For detailed 10-page brochure, write or phone directly to **MOR-GAIN**, P.O. Box 329T, Leavenworth, Ks 66048. Tel. (913) 682-3142.

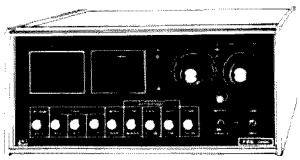
RTTY Demodulators

Here is no compromise design and construction:
- Unparalleled selectivity achieved with sophisticated limiterless design utilizing ultrasharp active filters and decision level correction circuits
- The most flexible interface system available to computers and high voltage loops
- Built in 170 volt loop supply
- Selectable bandwidths of 55 and 100 Hz. (copies 110 Baud ASCII)
- Continuously tunable shift coverage
- Rugged construction - commercial quality throughout
- Full complement of rear panel connectors for easy interface
- Keyboard activated switch for break in operation
- Individual tuning meters and LED's for quick, accurate tuning



FSK-1000™

This RTTY demodulator is designed for computer interface but is a fine stand alone unit:
- Easy computer interface with RS-232 or 5 volt logic signals
- Three shift coverage without straddle tuning
- Selectable bandwidths give you optimal Baudot or 110 Baud ASCII copy
- Input bandpass preselector using active filters
- High voltage loop keyer output
- Autostart built in
- Three shift AFSK keyer plus narrow shift CW ID
- Fully wired and tested: ready to copy!
- The FSK-500 is the best demodulator available for under $500.00 (Except for our FSK-1000!)
- Positive tuning with meter and LED's

CORRECTIONS

The TVRO filter/amplifier and demodulator circuit boards shown in "'Lite Receiver IV," May, 1982, are double-sided. The foil patterns for the component (top) sides of these boards are given here as Figs. 2 and 3.

J. Richard Christian WA4CVP
Mobile AL

Please note the following information:

- The coaxial collinear described in "Omni-Gain," an article in the May issue of *73*, is incorrectly shown in Fig. 3. The ¼-wave stub should be shorted at both ends, as described in the text.
- A complete kit of parts for the "Fun-Amp" featured in the May, 1982, issue is available from Radiokit, Box 4115, Greenville NH 03048 for $37.95.

Tim Daniel N8RK
***73 Magazine* Staff**

The printed circuit board layout for "Home-Brew a TVRO Downconverter," March, 1982, should have included both sides. The top and bottom of the board should be etched as shown here in Figs. 4 and 5.

Also, the three coupling capacitors shown in the parts placement diagram should be 50-pF disc ceramics, not the .01-uF ones shown.

S. F. Mitchell WA4OSR
Mobile AL

SATELLITES

BEYOND PHASE IIIB

With the Phase IIIB launch still set for early July, there are now increasingly bright prospects for geosynchronous launch opportunities for amateur satellites. It appears that there may be two such possibilities by the end of 1985. The first of these is a test flight of a vehicle designed for launching a new US defense satellite. The second is a test launch of a new European Space Agency (ESA) vehicle called Ariane 4.

In both cases, the available payload is enormous by amateur satellite standards: 1200 pounds for the US launch and 4400 pounds for the ESA flight. Needless to say, AMSAT officials on both sides of the Atlantic are pursuing these unique opportunities. It has been suggested that the time may be at hand for AMSAT to coordinate its activities with other amateur space groups, in order to make full use of the large payloads. It may well be a case of "use it or lose it."

SPACEWEEK: JULY 16-24

The week of July 16-24 marks the 13th anniversary of the Apollo 11 flight, during which man first set foot upon the moon. "Spaceweek" is a national celebration to commemorate this historic event and to demonstrate public support for space exploration. Activities include exhibits, lectures, and a petition drive to show our leaders in Washington DC that Americans really do favor an active role in space for the United States.

Spaceweek activities in each local area are organized by volunteer groups. The *Spaceweek Handbook*, which tells how to conduct a local Spaceweek, is available from the group's headquarters for a $10 donation. Write to Spaceweek National Headquarters, PO Box 58172, Houston TX 77258.

The above informaton is courtesy of *AMSAT Satellite Report*, PO Box 27, Washington DC 20044.

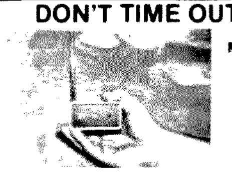
DON'T TIME OUT . . . 'TIME IN'



Model TI-10 time alert for repeater operators to avoid timing out the repeater

Resets on carrier drop-out
Piercing, 6.5 KHz alert tone
Adjustable timing period
Can be used as I.D. reminder

Sensitive enough for handhelds
100% solid state; no relay switching
Handsome styling, durable case
Battery Powered;
Senses RF carrier—no connections to rig

Model TI-10 assembled $69
Model TI-10K, kit form $57
Printed Circuit Board and Documentation $20
Shipping and handling . . . . add $3

When ordering, please specify model. If you act before July 4, 1982 receive a $10 discount on the TI-10; $5 discount on the TI-10K

COMMUNICATIONS DIVISION

(We Speak Your Language.)

Backed by over 54 years of experience, Harvey continues to offer the broadest selection and finest service available for the amateur radio community. This experience has taught us that the ham needs special treatment and that is why Harvey has established a special division dedicated to the needs of the U.S. and foreign ham alike.

One thing is for certain. A ham will never get the run around from Harvey. If we don't have something in stock, we say so and will order it for you—or—tell you where to get it. However, we are sincerely dedicated to the ham community and, as a result, our expansive inventory means that, more than likely, we will have what you are looking for *in stock*.

LOGIC PUZZLES

Recently, on a day when 15 meters was dead and I had nothing else to do, I pulled out my Dover Books catalogue and began thumbing through its pages. For those of you not acquainted with this firm, Dover is a company specializing in all types of quality paperback reprints priced from about one to five bucks. Within the pages of their catalogue, you can find books on subjects ranging from dying cloth with crushed insects, to the complete engravings of Albrecht Dürer. They also have a selection of old-fashioned postcards that can be made into fantastic QSLs.

At any rate, I'm plowing my way through this catalog and what should I see listed but a book by Hiram Percy Maxim. Yes, *the* Hiram Percy Maxim. As I mentioned in a column back in 1980, among HPM's many accomplishments was an autobiography entitled *A Genius in the Family* (later made into the 1946 movie *So Goes My Love,* starring Don Ameche and Myrna Loy). Well, it seems that Dover has dusted off this mighty tome and is offering it to an anxious public for the tantalizing sum of $1.50.

If you're interested in ordering a copy (and should any *real* ham be without one?), you'll find it on page 52 of the 1981-82 catalogue listed between *The Handbook of Pictoral Symbols* and *Obedience Training For Your Dog.* To order, write to Dover Publications, 180 Varick Street (slightly south of the FCC), New York NY 10014, and ask for book 20948-2. Be sure to add 70¢ for handling. I can hardly wait to see the faces on the people at Dover when they suddenly get a few hundred requests for a book by Hiram Percy Maxim.

Last January's logic puzzle in the Reader's Corner seems to have struck a responsive chord. In fact, since the puzzle appeared, I've received over two dozen letters asking for more problems devoted to logic and reasoning. Since FUN! always aims to please its readers, this month we're dedicating the entire column to logic games. These puzzles are by far some of the most complex riddles ever published in FUN!, so be sure to keep a glass of ice water or some other suitable refreshment nearby. We don't want to burn out any brains.

ELEMENT 1—THE REPEATER COUNCIL

The Northern South Dakota Repeater Council has a highly involved system of repeater group representation. According to the rules of the council, each repeater is represented by four members, but because of overlapping repeater club memberships the following complications exist:

- Each person on the council is simultaneously the representative of two different repeater groups.
- Every pair of repeater clubs has one representative in common.

In this maze of conflicting allegiances, the NSDRC accomplishes little in the way of frequency coordination, which isn't unusual for a group of this sort. Nevertheless, the council's organization presents an interesting puzzle, which is: *How many repeater clubs are represented on the NSDRC and what are the total number of representatives?*

ELEMENT 2—THE JAMMER

A recent murder case involved the homicide of an alleged repeater jammer. In one order or another, six hams, Walt, Jimmy, John, Bob, Nat, and Harvey, were the victim, the murderer, the witness, the policeman, the judge, and the hangman. Here are the facts of the case: The victim had died instantly from the effect of a close-range gunshot wound. The witness did not see the crime committed, but testified to hearing an altercation followed by a shot. After a lengthy trial, the murderer was convicted, sentenced to death, and hanged.

- Nat knew both the victim and the murderer.
- In court, the judge asked Walt to give his account of the shooting.
- Harvey was the last of the six to see Jimmy alive.
- The policeman testified that he picked up John near the place where the body was found.
- Bob and Harvey never met.

What role did each ham play in this tragic story?

ELEMENT 3—DXCC COUPLES

Many husbands and wives are avid DXers. One afternoon, Stan, Frank, and Joe, along with their wives, whose names in random order are: Susan, Wilma, and Diane, got together to compare their DXCC totals.

- Diane, Wilma, Susan, and Frank have 206, 202, 200, and 194 countries respectively.
- Stan and Joe have 198 and 196 countries, but for some time they couldn't tell who had made which since they both had bad memories and lost their copy of *QST.*
- When the fellows finally found the *QST,* it turned out that two of the couples had the same total.
- Frank's wife has more countries than Stan's wife.

What is the name of each man's wife, and how many countries do Stan and Joe have confirmed?

ELEMENT 4—CENSORED MULTIPLICATION

The following example of multiplication has been attacked by the "Math Censor." He's taken most of the digits in this problem and replaced them with x's. It's up to you to restore the problem to its correct form. (Note: The 4s, 5s, and 6s remaining are not necessarily the only digits of those values in the example.)

```
      6 x x
      x x x
      -----
      x x x
    x x x x
  x 5 x 5
  ---------
  x x 5 x 4 x
```

Uncensor those digits!

ELEMENT 5—THE ORGANIZATION

Six hams: John, Mary, Carl, Stan, Harry, and Dick, are the only people interested in running for the offices of president, first vice president, and general manager of a certain national organization.

- John won't be an officer unless Harry is president.
- Mary won't serve if she outranks Carl.
- Mary won't serve with Dick under any conditions.
- Carl won't serve with both Harry and Dick.
- Carl won't serve if Dick is president or Mary is general manager.
- Stan won't serve with Carl or Harry unless he outranks them.
- Harry won't be first vice president.
- Harry won't be general manager if Stan is an officer.
- Harry won't serve with John unless Dick serves too.
- Dick won't serve unless either he or Carl is president.

How can the three offices be filled?

THE ANSWERS

Element 1:
There are ten persons representing five repeater groups.
Element 2:
Walt was the policeman, Jimmy the murderer, John the witness, Bob the victim, Nat the judge, and Harvey the hangman.

Element 3:
Stan is married to Diane, Frank is married to Wilma, and Joe is wed to Susan. Stan has 198 countries and Joe 196.

Element 4:

```
      645
      721
      ---
      645
    1290
   4515
   ------
   465045
```

Element 5:
Carl is the president, Mary the first vice president, and Harry the general manager.

SCORING

Element 1:
Twenty points.

Element 2:
Twenty points.

Element 3:
Twenty points.

Element 4:
Twenty points.

Element 5:
Twenty points.

Let's get logical.

1-20 points—Scatterbrain.
21-40 points—Utterly confused.
41-60 points—Room temperature IQ.
61-80 points—Computer-like.
81-100 points—Mr. Spock.

The following amateurs were missing from last month's list of those solving January's Reader's Corner. *Found 1 solution:* Ed Larose KS5V, John Hufschmid KI9J, Bob Kendall VE4ZH, and Marien Kendall XYL-VE4ZH.

COMBATTING THE SUMMER DOLDRUMS

Doldrums. A state of inactivity, stagnation, or slump; a spell of listlessness. What the bands do in the summer. The pits. What do the enthusiasts of the various bands do during the summer doldrums?

The high level of atmospheric noise (QRN) ruins the lower frequencies for most DX. The 160-meter specialist disconnects the rig and spends the summer nights sleeping, dreaming of living on a mountain of copper plate. His days are filled designing the perfect ground and wondering if his neighbors will notice those copper wires in their swimming pools.

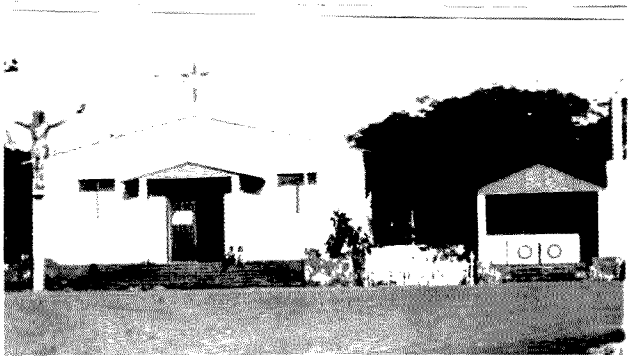
The 80-meter enthusiast splits his time between repairing winter-damaged wire antennas and checking the noisy sunrise and sunset openings for some other masochistic DXer. The pickings on the band are poor. There are too many leaves on the trees to shoot the arrow through the branches and haul the antenna up anyway. Maybe there's a baseball game on the tube.

The 40-meter DXer paces off his imaginary 2-element monobander in the back yard for the fifteenth time. No matter where he places the tower, the elements will hang over his neighbor's yard. That neighbor, of course . . . is the one who has never been very friendly since that incident with the TV set. It looks like another season with the inverted vee. Maybe a reflector element hung between that light post and the fence . . .

Twenty meters stays open, after a fashion, all summer. The high absorption and occasionally high noise level combine with amateurs pushed down from the higher bands so conditions are hectic. But it is possible to make contacts outside your continent. Antenna work can wait until the winter proves that the beam really is too big and blows it over.

Fifteen meters flashes with occasional excitement; it's probably the best band to watch carefully during the month. The

Father Dave Reddy, O.F.M., CE0AE. The Chilean flag has flown over Father Dave for years.



The Catholic church overlooking Main Street, Easter Island. Antennas mark CE0AE.

CE0AE as most of the amateur population sees (hears?) him. Father Dave's 5BWAS sits above the list of countries needed, the latter always at hand.

band opens toward the sun in the morning, often very rapidly. The most distant stations fade rapidly as the MUF climbs, but the shorter path DX stays strong for hours. The sunrise and sunset hours at the DX location remain the best bets.

Ten meters suffers badly from the summer doldrums. But the changeable ionosphere does give the band a little pizzazz once in a while. 15 meters provides a good predictor of 10-meter band openings. As 15 meters shortens up (the more distant stations lose signal strength, the closer stations improve), 10 might be opening in that direction. A rapid shortening of 15 suggests tuning to 10 and trying a few CQs. The first few stations on the newly opening band get the best DX.

Six-meter fans are finding F2 propagation scarce, but the always-exciting E-skip keeps the summer interesting. Solar flares liven the band a couple of times during the summer, but the real excitement awaits the return of shorter days.

DX activity and the overall level of effectiveness of the bands do indeed drop during the middle of the summer. The increase in solar radiation during the longer days increases the absorptive properties of the ionosphere much more than the refractive ones. The signals aren't escaping into space as they do when the maximum usable frequency is low. Our radio waves are being absorbed by the same ionosphere which permits long-distance communications in the first place.

But a few bright spots shine through the murky bands. The declining sunspot cycle flashes with a fickleness which strikes terror in many a propagation forecaster. A sudden solar flare can produce the most incredible long-path openings one night, and drive the absorption so high the next day that you can't work across the block. But favorable conditions as the flare just starts make up for the crummy conditions the next day or two.

Take advantage of these transient gifts to the dedicated DXer by checking the bands at least twice a day. Monitor WWV on a couple of different frequencies, if possible, until you can tell when conditions are a little strange, a little wilder than normal. Try some of those long-path directions and times. Most superb band conditions pass unexploited because "everyone knows the band isn't open *then*!"

Another encouraging aspect of the summer doldrums is the occasional cool breeze of good conditions. The level of absorption varies daily and frequently drops low enough to permit some good DXing. Again, daily or twice daily monitoring and occasional transmitting ensure catching these openings.

But during these months of perfect weather, between the occasional flashes of real excitement on the bands, this writer's attention begins to wander. I start to think how some of the South American amateurs are contending with the winter storms, amateurs such as our *73* profile: CE0AE.

When a visitor walks slowly up the wide, dusty main street, he looks toward the church square, drawing attention from the crumbling walls and rust-stained roof of the church itself.

But what is that sticking up above the roof of the church? It looks like. . . it is! A multiband vertical, with radials strung out just over the roof line. An RG-58 feedline runs off the back of the church and crosses over a long-neglected garden to a tiny house, overrun with vines and cats. A garden gate hangs from a strap of rubber tire under a collapsing grape arbor. The person who lives here has interests other than gardening.

Indeed, a telltale crackle from the window on your right hints at the avocation of the long-time resident: That smooth CW radiates from the fist of Father Dave CE0AE, on Easter Island, in the Pacific.

Father Dave Reddy, O.F.M., landed on this remote rock, thousands of miles from any other inhabited land, on the recommendation of Father Sebastian, the former Catholic priest of Easter Island. Father Sebastian, widely recognized as the father of modern archeology on Easter Island, as well as father of his flock, interviewed Father Dave in the United States shortly before the former's death. Soon thereafter, Father Dave embarked on the fulfillment of a longtime dream: operating ham radio from the South Pacific. He left the seminary in Buffalo, New York, where he had been teaching, for Santiago, Chile, to learn Spanish.

His arrival in Chile (the country which controls Easter Island) was untimely. Leftist leader Alliende rode to power on the back of anti-American slogans, and Father Dave could not get the necessary permission to assume his role as the spiritual leader of Easter Island.

Although the journey was neither short nor straight, Father Dave did finally arrive on Easter Island, with built-in status as one of the leaders of the tiny island. His predecessors in the role of Pastor of Isla de Pasqua helped forge a nucleus of "Who's Who" on Easter Island along with the Governor, Mayor, and heads of the small military units on the island. Father Dave rapidly forged another reputation as an active and congenial amateur radio operator, CE0AE.

Today, Father Dave welcomes visitors with the same friendly cheer so well known to his on-the-air contacts. His hearty laugh and ever-present smile and good humor provide a welcome touch of the States in this remote corner of the world. His Long Island twang, which strongly colors his Spanish, betrays his New York heritage. The visitor suspects he welcomes the chance to speak English other than "59 100."

It is hard to say which of the items I brought from the United States Father Dave most appreciated: the spark plugs and replacement gearshift knob for his jeep, the diodes to repair a seldom-used Collins 30L1 amplifier, or the two big jars of chunky peanut butter. I suspect the last. The food on Easter Island is monotonous and expensive, and the passing of the plate at the Sunday service permits few luxuries.

The presence of amateur radio visitors promised another bright spot in the slow life on Easter Island. Father Dave welcomed the assistance of the visiting amateurs in improving his antenna farm, heavily damaged by the storms which sweep in from the northwest. Spare parts and tower-climbing ability are scarce in Easter Island, but the generosity of his amateur visitors and a little help from some passersby left CE0AE with a credible set of skyhooks.

Father Dave divides his time on the Isla de Pasqua between his church, DXing, and his Boy Scout troop, one of two on Easter Island. On Chile's Constitution Day, he organized the Scouts into the parade, then raced to join the other island authorities in the viewing stand. The Scouts themselves quickly joined the viewers at the side of the parade route as soon as they passed the viewing stand. There simply aren't enough people on the entire island to both have a parade and have people watching it. Everyone serves double duty.

A good time to work CE0AE is during a contest. He lets few pass without at least a few contacts. He claims a *laissez faire* attitude toward amateur radio contests, but his actions suggest a more positive attitude toward their periodic madness. When his 10-meter signal appeared to be interfering with the public address system in his neighboring church, Father Dave would hear none of any suggestion that the visiting amateur curtail operations during

the Sunday service. "Nonsense! You go right ahead and operate. I'll turn off the church mike and talk louder." And he did!

While Father Dave often can be found in contests, he admits he prefers DXing to contesting. Easter Island lies south of the tropics, and the band conditions are not as uniformly superb as in the West Indies or other more northerly islands in the Pacific. So band openings to the heavy amateur concentrations in the Northern Hemisphere are shorter and not as strong as those enjoyed by his competition in the tropics. And the absolute lack of any local contacts makes serious contesting difficult. Easter Island is no place to go to win an amateur radio contest, despite the extra 20 dB the CE0 callsign imparts.

"Besides," Father Dave reminds his visitors, "Sunday is my busiest day."

Father Dave shows some of the signs of the hard-core DXer: His greatest fear is that he won't get on the Honor Roll before Easter Island loses its status as a separate country.

Easter Island no longer a separate country for DXCC? Father Dave explains, "Continental drift is sweeping Easter Island toward mainland Chile at the rate of 2 inches per year. We'll be within 225 miles of Chile and lose our status as a separate country in only 70 million years. I hope I can work the last 47 countries I need before then."

How can you increase your chances of working Father Dave next time he shows up on 15 meters? Maybe you should review the phonetics for your callsign.

CHOOSING YOUR PHONETICS

(This part of the column is for phone operators only; we'll get to the CW crowd in another column.) Proper choice of phonetics can spell the difference between success and failure in DX pileups. How do you choose the most effective phonetics for *your* callsign?

Think about why you use phonetics: The purpose is to reduce ambiguity. So many letters sound the same in the English language: b, d, e, t, p, g, c, v, z. Even under perfect conditions, most DX stations confuse stateside calls. In the confusion of a typical phone pileup, these letters are impossible to tell apart. So you turn to phonetics.

You want the DX station to recognize (and come back to) *your* callsign, and hopefully before he comes back to someone else's. So your phonetic callsign should be unique, it should reduce confusion, and it should be easy to copy through the pileup. Does your phonetic call meet these objectives?

THE CHOICES

The first place to look for phonetics is the standard list found in any amateur radio handbook or training manual. This standard list is remarkably good, but it does have a few problems for DXers. One example: After making thousands of contacts as WA1SQB, I would like to personally throttle the idiot who picked "sierra" for S. Sierra is C. I still hear sierra and write C. "Sugar" gets through as well as sierra, without the ambiguity.

Short phonetics punch through pileups faster than long ones. The amateur who uses short, punchy phonetics can get his call in twice as often as the ham who uses longer ones. Guess who works more DX? "Fox" is vastly preferable to "Florida." And the DX station can fall asleep or, worse, work someone else, while I struggle with "Washington American One Santiago Quebec Bolivia Portable Victoria Portugal Nine."

Which brings us to another possible source of phonetics—place names. Place names make long phonetics, usually too long for pileup situations. But they can be used to good advantage in poorer conditions or to confirm a callsign. All place names share a common disadvantage as phonetics, however. Upon occasion they cause more confusion than they eliminate! Witness my callsign above, and the DX station answers, "The station in Bolivia, stand by. The Portuguese station, go ahead!"

One well known contester turned this problem into an advantage. WA1KID would often break through pileups with "WA1KIDelaware." Ethical DXers frown on such use of deceptive phonetics, however, and you will quickly find this practice leads to more harm than good.

A final hunting ground for possible phonetics: "cute" or catchy phonetics. Such as Black White Yellow, or Whiskey One No Good. Or the famous Cute Enema Seashore. Topical phonetics fall into this same category. When the race horse Seattle Slew won the Triple Crown of racing, K7SS tried Seattle Slew for phonetics.

How do you choose the best phonetic from this assortment? We'll examine how you "fine-tune" your individual phonetic for your voice and station next month.

LETTERS

THE LAST TRAGEDY

Shortly after the article "The Father of FM" (February, 1982) appeared, I thought I'd look-see for myself. Perhaps a few pictures would be in order. Sure would be nice to add to the club history (the Major Armstrong Memorial Radio Club, Alpine, NJ, on the site of the tower described in his later experiments). Several passes were made to find the location, and at last I found it hiding ingloriously behind a huge apartment, the number, 1032, hidden under many coats of paint and hard to distinguish.

There above me on the hill to the east she stood, empty, burned, and blackened, overgrown with weeds and unattended flora, alone, abandoned, utterly destroyed. Though windows below were boarded, the door swung freely in the winter wind; a foreboding feeling crept over me as I entered.

Local youths, it appeared, had added their mark to the already sickening sight. Fearfully I entered, as one would an unknown tomb, feeling the evil of such a deed. Slowly, I climbed to the room where it all began, up the main stairs which, under the paint removed by the heat, showed a lovely balustrade—the kind so many are now restoring back to the way they used to be.

If only it had had a chance, it too could have been restored as have been the homes of many of America's lesser heros, but the shame of the Bronx has reached a few miles north into Yonkers.

There before me was the room—the one with the three windows—where it began. The sounds of those words rang in my head and lifted up into the sky above. Open into the universe. Another tragedy in the tale of Major Armstrong unfolded before me and you.

And so the last tragedy in the life of Major E. H. Armstrong passed one cold December 16,

1032 Warburton Ave., Yonkers, at present. For "then," see p. 51 of the February, 1982, issue.

1981, shortly after 8:00 am, carried by the heat and smoke into eternity.

God bless his memory.

Art Bonte W2ZYC
New Milford NJ

SIX-METER NETS IN DC

The Metropolitan Communications Network Radio Club of the greater Washington (DC) area operated a repeater on six meters (52.250 MHz in; 53.250 MHz out). We would like to have repeater clubs operating six meters anywhere along the eastern seaboard contact us to establish some linkage and exchange experiences. The six-meter FM net meets Saturday at 1900 hours local time. We also have a six-meter AM net which meets Sundays at 0900 hours local time on 50.4 MHz. Sunday at 1900 hours local time we have a six-meter sideband net which meets on 50.125 MHz.

Robert Sporn WA3GGO

Silver Spring MD 20903

WRITE FOR RIGHT HAMS

As a regular reader of your excellent publication, I enjoy reading your often-controversial editorial comments and the letters page, but I have now been forced to write on behalf of the large number of amateurs outside the US without whom there would be no DX. It seems that all your comments do not take any account of the very important international-contact part of our great hobby. Please bear in mind that you are no more a representative of the radio amateurs than is the editor of the *Washington Post* or the *London Times* of their respective readerships, and please take us DX operators into account.

I would also like to comment on some aspects raised in your issue of March, 1982. Concerning your promotion of a no-Morse license, I am definitely against this, especially as we in Britain have had a no-Morse VHF license for some years. As I operate both in the US and at home on both the VHF and HF bands, I have noted that despite the much larger number of US amateurs, you have a much smaller proportion of lids. Have you ever listened to the London repeaters? Also, the operating standards of US amateurs to me are much higher than the average, especially on CW. I am sure that this difference is a result of your Novice system, that I would like to see copied in the UK.

This brings me to my next subject of emergency communications, although nobody can fault your suggestion for a national data network (international?) for traffic handling. I believe that once main power supplies have gone, as they certainly will in a conflict, we will be back to CW. I believe that we should propagate some return to basic, but modern, technology in amateur radio coupled with CW operating so that in the final emergency we amateurs can salvage some communications from the remains.

Andy Hewitt G3SVD/W4
Thatcham, Berkshire, England

I can see you've never tried our repeaters in New York or Los Angeles. I monitor the London repeaters when I'm there. . .no comparison to the antics we are able to generate. Andy, where are we going to get all those CW rigs? Most of the SSB and FM ham gear these days can operate from a car battery as well as the mains. A large part of the emergency gear is mobile and hand-held equipment anyway. I can just see us all sitting there with a hand key sending messages via our handie-talkies. Perhaps some forward-looking firm will come out with a hand-key kit to provide keys which will screw on to our HTs in case of emergency need. We could even have the code printed on it for those of use who have forgotten the code.—Wayne.

A RIGHT HAM WRITES

I think that you ought to write a couple of things about Novices. I'm 12 years old and I'm a Novice. I see a lot of articles on things pertaining to General class hams but nothing about us Novices. Thanks for your time. I think your magazine is great!

Eric Farwell EF2XJI
Miami FL

Eric F., you are absolutely right! Let's see some more articles to help our Novices understand more of what is going on. We need to get them interested in simple antennas and how they work, introductions to some of our more exciting activities such as traffic handling, SSTV, ATV, RTTY, certificate hunting, contests, and so on.—Wayne.

NO MORSE A NO NO

I am writing in disagreement with your feelings about CW. Evidently you don't operate CW. I operate CW and enjoy it. I am 14 and was first introduced to ham radio when I was 11. I was attracted to ham radio because of CW; it seemed interesting. I was not scared off by CW when I was a newcomer. I work lots of CW. I do also work SSB and enjoy it, too. CW is *not* (for most) just "the usual garbage of name, location, signal strength. . ." etc., as you stated in an answer to a letter in the April, 1982, issue. I'm a ragchewer and do mostly that, though I do some DXing and contesting. I don't just give my name, QTH, etc. I talk about my family, the day, school, my future, electronics, etc. CW is fun and rewarding. CW is the root of ham radio. CW is what makes ham radio special. I am *completely* against "no-code" licenses; the last thing I want to hear is ham radio sounding like the Chicken Band (CB). So my conclusion is that CW is fun and thoughts *are* expressed on CW.

Eric Lassiter KA4KEG
Danville VA

Hey, Eric L., I'm glad you've found some chaps on CW who will give you more than the usual dull routine. That's great! Not that I can in any way single out CW for that crime. It's all too prevalent on our repeaters, and certainly not unknown on our DX bands. And I don't know of anyone who wants to have our ham bands sounding even more like CB than they do, so stop fretting about that. Perhaps I put more trust in the intelligence it takes to understand radio theory than I do in the skill it takes to copy code. I do know that you would be hard put to point out any of the more serious offenders on our bands as being good technicians. I tend to gravitate more toward hams with technical backgrounds, and to find them the most sincere and fascinating of all hams.—Wayne.

NO CODE A YES YES

Sir, I sincerely applaud you for your editorial in the March, 1982, *73 Magazine*. I find your logic in a no-code ham ticket as being beyond reproach and agree whole-heartedly with your comments. Do not give up on this, as you will prevail.

One of the most frustrating experiences I have had has been wanting to get a ham license and to do experimentation in communications. As a result of this frustration, I turned to CB radio. Most everyone knows there is a problem on 11 meters, but fads have a way of fading away, leaving only those that are sincere. The only drawbacks in my getting into ham were two items, one a myth and the other what now should be a legend, to wit: you had to spend a lot of money on equipment, and code. As has been evidenced, you can get on the air in a respectable manner without having to sell the wife and kids.

The other item, code, is rhetoric used by the elitists to keep it all to themselves.

Selfish and unconcerned as to the future of ham radio: "I had to do it, so should you," attitudes. If we were to use the logic many hams profess, we'd still be in knickers until manhood, women would not be able to vote (hmmm), and we would have legal slaves. Trying to keep code as a requirement is analogous to keeping a person on a respirator who has suffered "brain death."

I cannot for the life of me find any logic in the license requirements for code. 5 wpm, Novice, CW only; Technician, CW and phone on some VHF; 13 wpm for General and Advanced for. . . *phone* privileges? Like putting the cart before the horse, bass ackwards. In any case, code should be like blacksmithing, an art of an outdated requirement. Those who want it, do it; those who don't, won't. Code, like saving string, serves no useful purpose but you keep hanging on to it.

We need technical innovations and experimentation by those who sincerely want it while, on the other hand, providing a hobby to many. I am trying to get our local Community College to carry a non-credit course in the aspects of ham technology. So far no luck, but I will continue to try. I feel that we as Americans need to recapture the reputation for being leaders in technological advancements rather than also-rans. To do this,

we must take down our self-imposed barriers and "motivate, not frustrate" (a good anti-code slogan) new blood into ham.

I'll learn the code in order to upgrade, but I will then drop it like a bad habit. I guess that means some people will label me as a lid or other terms they put on those who want to move forward, not stay in the past. If people would sit down and unemotionally analyze the no-code proposals, using reality, and not negatively speculate on what would happen, only positive things could come about. For those who cannot follow the rules and regulations as set down, what we need is stronger enforcement of the rules, not outdated requirements such as code.

FCC has its heart and hands full in light of the budget cuts, etc. It needs help in enforcement of the rules. This could be accomplished by the use of hams themselves. Testing could be done on a local level by a group or club of hams. In my case, I would have to go to Long Beach, California, to upgrade. This would cause me to miss two days of work. Or, glory be, I could wait to see if the field office will have enough money to make a trip maybe 2-3 times a year to come to where I live.

Using local hams to upgrade future hams would also instill pride. It wouldn't take long to find out which groups are upgrading really qualified hams, as the proof is in the pudding. Nothing wrong in taking pride in knowing that your pupils have been properly supervised, instructed, and motivated in the correct methods and knowledge. However, the clout is in the hands of the diehards who insist on being outdated in putting political pressures on those who can change the code requirement. Until these "chosen" pass away to that great shack in the sky, I am afraid that the code will remain, regrettably.

There are so many positive aspects to dropping the code; if only those who wish to hold on to the past would take a *positive* view. Let's move ahead and become the leaders of advancements, not the sleeping giants that we are.

Frank J. Ward KA7LXT
Tempe AZ

Troublemaker.—Wayne.

HANG HI OL' YAGI

Even I can remember the time when one needed a yagi or a quad to work DX, the thrill of breaking a pileup, the sophistication of dual vfo's, tail-ending, and all the rest of that good stuff. To the new breed of ham, this sounds like weird talk indeed. The new DXer thinks you're out of the band when he hears about stacking five-over-five on a 180-foot tower. Who needs it? And he's right! These tales of working DX with yagis and amplifiers sound like echoes of the past, like the mumblings of bearded Honor Rollers about the gud ol' days. The new DXer knows where it's at. . .you won't find him staying up half the night in the hope of catching a rare one while the rest of the world sleeps. He's not going to spend hours calling CQDX in the hope of finding a rare bird. Hell no, he'll tune in to a DX net, of which there are now more than thirty. He'll get in line and work the rare ones without any fuss. "Like a telephone call," says one list-taker. "No cuss'n and scream'n."

We old goats have been taken in by the manufacturers, i.e., we were told it was necessary to have a beam and an amplifier if one wanted to be a successful DXer. Well, it took me five years to discover that all one needs today is a worry-free dipole and a barefoot transceiver and you can work the world.

Like an archaeological relic, a dinosaur crying out for a mate, I called CQDX today for twenty minutes on 15 meters and nothing came back. There I was with a fortune tied up in amplifiers and towers, yagis at 150 feet, and two-inch heliax. Nothing came back, so I spun up the band and there they were, twelve of them, all 5 and 9, and all semi-rare: D68, ZD7, EA8, EA9, 7Q7, 3V8, JW, and more, all sitting like clay ducks in a shooting gallery. One after another they came back to the squeaky off-frequency signals with 4 and 3 reports. (The callsigns were handed out by the control station to the DX station. Reason: speed and efficiency, of course, of course!) And what's more, everybody was happy. The gud ol' list takers stood by for the indoor dipoles and verticals. Only one guy failed to get his report, and he was using a mag-mounted Hustler whip on his rig in the basement. . .he said he would wait for propagation. (Gud man!)

We with the mile-high yagis and maximum-limit amplifiers are anachronisms, incongruities at this point of time. Down will come those relics of the past and up will go the trouble-free dipole or vertical, and out will go the amplifier. That stuff belongs with chrome-laden, 6-litre guzzler automobiles and 25-cent-a-gallon gas. Get with it, DXers, you're showing your age! Pileups are on their way out, the way individuality is out and organization is in. CU on the lists.

Don Newlanda VE3HGN
Colborne, Ontario, Canada

You don't have to be an old-timer to remember the days when men were men and the endorsement sticker belonged to the strong and the quick. But now the demand for DX is way ahead of supply. A DL can raise a huge 10-meter pileup on a weekday afternoon. Rare ones who prefer to avoid the melee turn to lists. What to do? Try contesting, where the big station is worth the trouble. There's still a place for your 8877s, Don.—WB8BTH.

IT DOESN'T COMPUTE

The basic reason for not renewing my subscription to *73 Magazine* is because I feel that Wayne Green is using it to further the use of computers and associated software for communications between hams. This, I feel, reduces the human touch involved in everyday hamming. Taking away the personality of the ham and replacing it with machinery will indeed make everyone bored with the hobby. This leads to reduced growth, which is the opposite of that which Wayne is trying to achieve.

We do need growth in our hamming hobby. This will not be denied. But to substitute computers for the personal touch is not going to hack it. Contesters, DX hunters, county hunters, and rag-chewers thrive on the personal satisfaction that comes from doing it themselves. From learning a new langauge—Morse code—to building their own projects, no matter how simple or complex, each and every ham has his goal within sight and obtainable. It only depends on his ability and determination to do so.

Wayne professes that involvement with computers will revolutionize the hobby. He is absolutely correct. It will do what he wants. It will have hams all over the world making contests no more complicated than picking up the phone and dialing across the states. If that's what hams want, then why are they spending their money on better antennas, higher towers, new radios, or any other gadget that they think will make their contacts better or stronger than anyone else's? Why don't they spend it on computers and software and take all the grief out of hamming?

Computer hamming will eliminate personal satisfaction, which will in turn eliminate the desire to be an amateur *radio* operator.

Jim Ory WD9ATJ
Plainfield IL

By golly, Jim, you are probably right! We just may be able to make it so amateur radio can be enjoyed by people who haven't the kilobucks to put up monster beams and run 10,000 Watts, as you seem to prefer. We might even be able to cut back on those fun pileups which have chased most of the DX operators off the air from rare countries. But just maybe the nuts who think a new country is worth getting killed for can be siphoned off into ever more complex automatic country working, thus leaving the bands more open for getting to really know some of the DX operators. You know, the FCC was opposed to letting computers into amateur radio, too. It apparently never occurred to them that, like a typewriter or a Teletype® machine, there has to be an operator. . .a live person. . .behind each computer. The computer is just another means of communicating, little different from CW, RTTY, and so on. It turned out that the FCC chaps had virtually no understanding of the situation and were acting normally . . .fighting any efforts by hams to experiment and perhaps provide the world with some progress. Obviously, Jim, you've managed to arrive at your convictions without taking the time to ask anyone involved with

computers about the real skinny. Find out what you are talking about first. . .then think it over. . .then, and only then, go on record. Remember, Jim, that when I write something I know I will be faced with about 200,000 skeptics, each one more interested in blowing a hole in my reasoning than in agreeing with me. . .so I have to be darned sure I have the background to know what I am writing about. Jim, I'm ready to stand up in front of any assemblage of hams and discuss Morse code, its pros and cons. I've been at that for some thirty years now. . .and, as I've said, it has been quite a few years since I've heard anything new. Jim, you haven't the slightest idea of what computers may do to hamming since you haven't tried them. . .and apparently don't know anyone who has.—Wayne.

THE GREAT GRATER

So Wayne the Grate (just a small pun) has again taken up the Holy Grail, this time in the form of abolishing the code requirements for ham licenses.

I admire you for the courage of your convictions, Wayne, but there are more than a few of us out here who have strong objections to a no-code license, myself included.

I am a newer ham (since 1977), an electronics engineering technician, own my own personal computer, and am an active member of the Tucson Amateur Packet Radio Club. I only say this in order to dispel any idea that I am of the "fraternity" that dislikes the introduction of new technology into ham radio.

When I received my ham license in the mail, I felt something that I'm sure no CBer has felt when his permit arrived. That feeling is a sense of accomplishment. I *earned* this license, and it is that feeling that binds me together along with the majority of other hams. A "cut above," if you will. The day that bond is gone is the day that the Amateur Radio Service ceases to exist. All remaining motivating factors will be self-centered, and no longer will hams work for the "good of amateur radio."

But that is not why I write this letter. I enjoy your magazine very much, Wayne, but a couple of things disturb me. First of all, your "Holy Grail" editorials tend a bit toward ranting and raving. That can't be good for the blood pressure or the digestion. I also have noticed that your replies to the letters protesting your editorial views are usually longer than the letters themselves. My psychologist friend has some interesting things to say about that. In short, take it easy, Wayne. This would be a pretty dull hobby sometimes if it were not for cage-rattlers like you, so try to rattle softer, so that you may rattle longer.

Dave Barnhart WB7OBG
Glendale AZ

Dave, I enjoyed your letter. But you should understand that no matter how much the cages rattle, I'm sitting here grinning. My blood pressure is fine. . .I give heart attacks, I don't get 'em. I'm happy that I give the impression that I'm real serious about all this. Oh, I do think that it is high time to dump the code as a means of keeping enthusiasts out of the hobby. . .and to supplant it with a technical exam which can't be totally thwarted by the Bashes and other cheating systems. If you read the license study manuals I put out, you'll see what I think is best. . . simple theory explanations which anyone can understand. Fortunately, I have reason and psychology on my side. . .and just an interest in getting things improved, not an overwhelming zeal. Zealots are not open to alternative ideas and get all emotionally involved in what they are doing. Oh, I don't expect Morse code to get dumped quickly. . .perhaps some experiments with this on 220 MHz, as I proposed to the FCC about thirteen years ago, to see if we can make the change from a filter of a very slight skill (code) to a not-much-more-difficult technical test. . .without the universal cheating via Bash. My letter answers are long, at times, so I can clarify misconceptions.—Wayne.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

JEFFERSON DAVIS DAY QSO PARTY

Contest Period:
1500 to 2400 GMT June 5

The Pennyroyal Amateur Radio Society is offering attractive certificates for contacts made during this year's annual event. Suggested frequencies are 3730, 3940, 7260, 14310, 21410, and 28610. Requests for certificates or more information should be addressed to Pennyroyal Amateur Radio Society, PO Box 1077, Hopkinsville KY 42240.

WORLDWIDE SOUTH AMERICA CW CONTEST

Starts: 1500 GMT June 12
Ends: 1500 GMT June 13

Sponsored by *Electronica Popular* magazine of Rio de Janeiro, Brazil, this contest will be held annually on the second weekend of June. Use all bands from 80 through 10 meters on CW only; crossband contacts are not valid. Only contacts between South American stations and stations on other continents are considered for scoring. A station may be worked only once on each band. Entry classes include single operator/single band or all bands, and multi-operator/single transmitter (multiband only).

EXCHANGE:

RST and consecutive QSO number starting with 001.

SCORING:

Each QSO counts 2 points. Contacts between South American stations count only as multipliers, not as QSO points. For South American stations, the multiplier is the number of different countries worked on each band. For others, the multiplier is the number of different South American prefixes worked on each band. The final score is the sum of QSO points multiplied by the sum of multipliers.

AWARDS & ENTRIES:

Certificates will be awarded to the three top-scoring stations in each class and to the top scorer in each country. A separate log for each worked band must be sent no later than July 31st to WWSA Manager, PO Box 18003, 20772 Rio de Janeiro, RJ, Brazil.

QSL OF THE MONTH: W8VFT

Sometimes, the design of a QSL card can capitalize on the unusual aspects of your station. It worked for W8VFT and his wind-powered setup. In fact, as the back of the card explains, W8VFT's entire homestead is powered by the wind generator shown on the card!

If you would like to enter our contest, put your QSL card *in an envelope* and mail it along with your choice of a book from *73*'s Radio Bookshop to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does *occasionally* damage cards) and do not specify a book will not be considered.

SUMMER SMIRK PARTY CONTEST
Starts: 0000 GMT June 19
Ends: 2400 GMT June 20

Sponsored by the Six-Meter International Radio Klub (SMIRK). No crossband contacts, multi-operators, or partial contacts. Check logs or dupe sheets are not needed.

EXCHANGE:

SMIRK number *and* ARRL section, foreign state, province, prefecture, or country. Count ARRL sections in the 48 US states only; KH6 and KL7 count as countries. Washington DC counts as a section as well.

SCORING:

Count 2 points for each SMIRK contact, 1 point for non-SMIRK QSOs. Add QSO points and multiply by number of ARRL sections, foreign states, provinces, and countries worked for final score.

AWARDS:

Trophies for high-score SMIRK in two divisions: US/Canada and foreign. Certificates for high score in each ARRL section and foreign state, province, prefecture, or country.

ENTRIES:

Entries must be submitted on

the fall, 1981, edition of the official SMIRK log. Single copies are available for an SASE and photocopies may be used. Send log requests, and entries postmarked by July 11th, to Spencer F. Ritchie KA2MHT/5, 5122 Sagamore, San Antonio TX 78242.

NEWSLETTER CONTEST WINNER

After a three-month hiatus, I was called upon again to choose a winner for *73*'s monthly newsletter contest. As usual, I put the task off until the last minute. This time, I was lucky; a "winner" jumped out at me. If you have an opportunity to read this month's choice, *The Log*, published by the Northern Ohio Amateur Radio Society, you'll see why.

The NOARS newsletter is not a one-man show. A rather impressive-looking masthead lists 25 names of officers, editors, and committee chairmen. The theory that many hands, working together, make for a light load applies here. *The Log*'s first page is rounded out by "Inside This Issue," a series of vignettes that make you want to turn the page and start reading.

NOARS editors KA8JRI and N8DNA make sure that there is something for everyone. They include reports for award chasers, the contest crowd, DX hounds, traffic handlers, and Novices. An historical series, "In the Beginning," will appeal to all the readers. A more somber *Log* feature is the "Silent Key" section, which incorporates the QSL cards of deceased members as part of a brief memorial.

In addition to their monthly newsletter, NOARS members receive an annual membership roster and a calendar that has the dates for club activities and operating events clearly marked. All this helps to convey the image of a lively, enthusiastic club.—N8RK.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

CERTIFICATE HUNTERS CLUB

All awards are issued to both licensed amateurs and SWLs on a heard basis.

Requests for band, mode, and power endorsements must be made at the time of your original application and must be correctly indicated on your log extract.

A verified log should be sent in lieu of QSLs. Have your log certified by a local radio club official, two licensed amateurs, or a notary public. Copies of your cards will be accepted in lieu of certification.

● WTP—Work The Pacific. The basic award is issued for confirmed contact with at least 30 countries in the Pacific area as set forth by the WTP country list. Gold seal: A gold seal is applied when 50 or more confirmations are achieved. Award application fee is $3.50 or 12 IRCs; overseas, add $1.00 or 3 IRCs; gold seal after original application, $1.00 or 3 IRCs.

● WTC—Work The Caribbean. The basic award is issued for confirmed contact with at least 20 countries in the Caribbean area as set forth by the WTC country list. Gold seal: A gold seal is applied when 30 or more confirmations are achieved. Award application fee is $3.50 or 12 IRCs; overseas, add $1.00 or 3 IRCs; gold seal after original application is $1.00 or 3 IRCs.

● Gold Seal Plaques. If desired, plaques are available for the WTP and WTC award series. When requested at the time of original application, your award is mounted on a walnut-grain 13" × 16" plaque, for $25.00. (Overseas, add $7.50 postage/insurance.) When requested after your original application, an engraved 4 × 6 solid walnut plaque denoting your accomplishment is available for $20.00. (Overseas, add $3.00 postage/insurance.)

● A-1—Operator's Certificate of Merit. Issued free of cost by the IARS/Certificate Hunters Club to amateurs observed displaying a high level of achievement in various areas of amateur radio. The award is also issued upon receipt of three nominations from three different amateurs in three different geographical locations. So, if you feel that an amateur should receive this honor, get out your pen and give us the details in writing. You do not have to be a member of the club or a holder of the award to nominate.

● County Awards. Issued in multiple classes for the differ-

ent numbers of counties confirmed, in 14 states. GCR apply; fee is $3.50. The awards measure 8½" × 11" and are printed on a fine parchtone bond. Other county awards will be made available as demand requires.

- 10 K and 20 K Awards. Issued for confirmed contact with 10 or 20 different locations outside the United States operating with a W, K, or N prefix. Award fee is $2.00 and band and mode endorsements are available.
- Work A-1s. Requires applicant to work A-1 operator certificate holders of any radio organizations issued for WAC, WAZ, WAS, WPX and DX(CC). All rules are the same as they are for the regular award. Award fee is $2.00 and band and mode endorsements are available.

For applications and additional information, send an SASE to the CHC Manager, Scott Douglas KB7SB, PO Box 46032, Los Angeles CA 90046.

WORKED ALL VE

Sponsored by the Nortown Amateur Radio Club of Willowdale, Ontario, the WVE Award requires the applicant to work two different stations on two different bands in the eight sections, VE1 through VE8. All contacts must have been made from an area within a radius of 150 miles of one point on and after January 1, 1939.

A sworn affidavit and certification by a local radio club official must accompany your application. Also, be sure to send all sixteen QSL cards, two from each section, along with $1.00 and sufficient return postage for the return of your cards. Address your application to the Nortown Amateur Radio Club, Box 146, Station A, Willowdale, Ontario, Canada M2N 5S8.

The Nortown organization also sponsors the WACAN (Worked All Canada) Award. Here the applicant must work two different stations on two different bands in each of the following twelve areas: VE1 (PEI), VE1 (NS), VE2, VE3, VE4, VE5, VE6, VE7, VY1 or VE8, VO1, and VO2.

All contacts must have been made on or after January 1, 1949, and a 150-mile rule applies, as mentioned for the WVE Award.

Send your list of contacts and QSL cards, with $1.00 and sufficient funds for the return of your confirmation cards, to the Nortown ARC.

TRANS-CANADA AWARD

The Canadian DX Association writes to tell us about their very beautiful award. To qualify, you must work each of the eight VE call areas, with five contacts in each area. In addition to that, another five stations must be worked in VO1 and/or VO2; one VEØ maritime mobile station must be contacted. One of the five VE8 contacts required must be from the Yukon Territory and one must be from one of the offshore islands of the Northwest Territories. In short, a total of 46 contacts must be made to meet the minimum requirements.

WAC 2-80 AWARD

Sponsored by the Metro Amateur Radio Club of Downsview, Ontario, the Worked All Canada 2-80 Award was originated in November, 1972. All contacts and confirming cards must be dated on or after that date.

To qualify, the applicant must submit QSL cards to verify two-way contact with one station possessing a two-letter call in each of the twelve Canadian sections. Are you wondering what the 2-80 stands for? Well, it means all contacts must be made with stations *only* with two-letter calls, and these contacts *must* be made only on 80 meters. Required sections include VO1, VO2, VE1 (PEI), VE1 (NB), VE1 (NS), VE2, VE3, VE4, VE5, VE6, VE7, and VE8. There are no mode restrictions, but endorsements will be granted at the time of applications if all contacts were made on a specific mode of operation.

Contacts must be made using your own equipment from one location or from within 150 miles of it and within the same section.

To apply for this award, enclose $2.00 and sufficient postage for the return of your award and the required confirmation cards. Address all your correspondence to the Metro ARC, PO Box 352, Downsview, Ontario, Canada M3M 3A6.

ALL NOVA SCOTIA COUNTIES

The Nova Scotia Amateur Radio Association is proud to announce the WANS Award, which requires the applicant to work fifteen of the eighteen counties in Nova Scotia, Canada, or fourteen of the eighteen counties plus a contact with Sable Island.

There is no charge for this award, but applicants are asked to send QSL cards and log data along with sufficient postage for their safe return. Address your application to Mrs. Christine Weeks VE1AKO, PO Box 47, Rural Route 1, Cleveland, Nova Scotia, Canada B0E 1J0.

The Halifax Amateur Radio Club also sponsors a Worked All Nova Scotia Counties Award which states that maritime provinces must contact seventeen of the eighteen counties in the province, while at the same time they must contact ten counties on a second band or series of bands. In all cases, Sable Island can be used as a substitute.

To qualify, all contacts must have been made on or after January 1, 1977, and the application should be sent directly to the Halifax ARC, PO Box 663, Halifax, Nova Scotia, Canada B3J 2T3. There is no charge for this award, but the applicant must supply sufficient postage for the safe return of confirmation cards.

DIPLOMA OF THE FRENCH AMERICAS

From Quebec City, Canada, comes word about the French Americas Award which requires stations in Europe, Africa, North, and South America to work at least two FP8 stations, two FY7 stations, and either an FS7 or FM7 station. Applicants in Asia or Oceania must work only a single contact from the areas of FP8, FY7, and FS7 or FM7.

There appear to be no date restrictions, and applicants may have their list of contacts verified by a local radio club official and sent, along with an awards fee of $1.00 or seven IRCs, to Alex Desmeules VE2AFC, PO Box 382, Quebec City 4, Canada.

QUEBEC CITY AWARD

Speaking of Quebec City, Quebec, the local amateur radio fraternity sponsors the Quebec City Award for American and Canadian stations which make a minimum of five station contacts in Quebec City.

You may address all correspondence to the Radio Club of Quebec, PO Box 332, Upper Town, Quebec City, Quebec, Canada. The award fee is $1.00 or seven IRCs.

WORKED ALL SASKATCHEWAN PROVINCE

The Regina Amateur Radio Association is pleased to announce the WASP Award which requires the applicant to accumulate a total of 100 points to qualify. Members of the Regina organization count 10 points each to a maximum of five contacts made with members of the group. Contacts with other Regina amateurs score five points, while contacts with other Saskatchewan amateurs count two points. There must be a minimum of ten QSOs made. Send your list of contacts along with your confirmed QSLs and $1.00 to RARA Club VE5NN, 2827 Abbott Road, Regina, Saskatchewan, Canada S4N 2J9.

STONEHENGE USA

The Tri-City Amateur Radio Club will operate a special event station Saturday, June 12, 1982, from the replica of Stonehenge located near Maryhill, Washington. W7VPA will operate from 1600 to 0100 UTC on or near the frequencies of 3.900, 14.290, 21.390, 28.690, and 146.52. An attractive certificate will be awarded. Send QSL info and $1.00 to W7VPA Special Event, PO Box 73, Richland WA 99352.

HOMEWORK NET

Are you a teenager? Or still think you are? Then the Homework Net is for you, operating on 7.250 phone every Saturday from 2100 to 2200Z. It is designed for, but not limited to, teenagers. This net is looking for young amateurs who wish to make new contacts with people who have similar interests. So take a break from your homework and join us on our informal Homework Net—Diane WD9DNQ and Scott KCØNF.

WATERLOO DAYS

The N. E. Iowa Radio Amateur Association will operate special event station WØMG in conjunction with activities celebrating My Waterloo Days, on June 12-13. Activity will take place from Waterloo, Iowa, and will be on 7.240, 14.290, and 21.370. Special informative commemorative QSL card for SASE to: NEIRAA, PO Box 92, Waterloo IA 50704.

DUNGEONS AND DRAGONS

New! A 10-meter Dungeons and Dragons Net at 28.720

± QRM. Saturdays promptly at 1500 GMT. To save us time and grief, please be ready with your character, rank, dice, and all of the necessary info. Net control is KA9JOX. If you don't hear anyone at 28.720, check 28.820. If still nothing is heard, the net has been canceled because of poor turnout or other reasons and will resume the next week at the same time and place. If you wish to participate regularly, please write me so you can get a chance to be a DM or net control. Address: Michael Frost KA9JOX, Box 1008, Riverside IL 60546.

FORT DELAWARE

Fort Delaware, on Pea Patch Island, Delaware, will be the site of a mini-expedition by Wilmington area hams on the weekend of June 5 and 6, 1982.

This will be the first HF amateur operation from the fort in the middle of the Delaware River where, during the Civil War, many thousands of Confederate prisoners of war were held. The fort is now a state park.

Equipment will be limited to one transceiver fed by a small generator carried to the island by a small boat. Operations will be in the General segments of the HF bands, daylight hours only, with each operator using his own call and the Fort Delaware identifier. Members of the Independent Amateur Radio Group of Delaware will be Rick KB3PD, Allen KB3HZ, Dwight N3ARU, Ned N3ARV, and Doug N3ACU. Commemorative QSL cards will be issued to contacts supplying SASEs.

For more information, contact the Independent Amateur Radio Group of Delaware, 400 Fifth Ave., Millcreek, Wilmington DE 19808.

NOARS AND *USS COD*

Once again, signals will be radiating from the submarine *USS Cod*. Members of the Northern Ohio Amateur Radio Society will be operating from this proud WWII warship during the months of June, July, and August, using the call K8KRG. The *USS Cod* is on permanent display in Cleveland, Ohio. Operations will begin on Memorial Day and run every weekend (with the exception of Field Day weekend) until Labor Day.

An attractive certificate will be awarded for two-way contacts from the ship upon receipt of QSL card and $.50 for postage. Look for operations in the lower part of the General bands, 10 through 80 meters, on the weekends of June 5-6, July 17-18, and August 7-8; we will be operating 40-meter Novice band at 7.125. Send QSLs to Donald L. Winner WD8RZG, 8927 Torrance Ave., Brooklyn OH 44144.

NORFOLK TRICENTENNIAL

The city of Norfolk, Virginia, will be celebrating its tricentennial this year. As part of the "Harborfest" celebration on June 11-14, the Tidewater area amateur clubs will join together to operate a Harborfest-Tricentennial special event station. The amateur call W4NV will be used, and special QSL certificates will be sent to all contacts made who send a large (8" × 10") SASE. The station will operate 24 hours each day in the 80- through 2-meter bands and will work CW and SSB.

For further information, please contact Bill Verebely KC4YX, 3101 Petre Road, Chesapeake VA 23325.

LARGEST TRAIN ROBBERY

The Libertyville and Mundelein Amateur Radio Society (LAMARS) will operate W9HOQ from Rondout, Illinois, near the site of the largest train robbery in United States history. Approximately three million dollars in negotiable instruments and jewelry were confiscated during a brief stopover and all participants were apprehended within six months. Frequencies: phone—7.260, 14.290, 21.375; CW—7.125, 21.150. Time: from 0000Z 12 June until 0000Z 13 June. Certificate for a large SASE to: KB9BR or "Big Robbery," Box 656, Libertyville IL 60048.

STAR-SPANGLED BANNER SPECIAL EVENT STATION

WB3KUH will operate a special event station from Fort McHenry, Baltimore, Maryland—the birthplace of *The Star-Spangled Banner*—on June 12 and 13, 1982. Operation will commence at 1600 GMT. Operation will be within the first 25 kHz of the General and Advanced bands. Both SSB and CW will be used. Novice operation is also expected. Operation will be on 20, 15, 40, 2, and 6 meters.

Stations desiring a special certificate from the event station can obtain one by sending an SASE and their QSO number to Donald Oakjones WB3KUH, 1806 Willann Road, Rosedale MD 21237.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time away from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print (neatly!), double spaced, your request on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am interested in corresponding with hams who have or had any late-model Hallicrafters equipment, specifically the SR2000 Hurricane transceiver, HA20 vfo, and P2000 power supply/speaker. I am interested in operational notes, modifications reviews, and comparisons.

I would also like to obtain information on the history of Hallicrafters equipment, particularly post-1958. (I already have a copy of the *Ham Radio* article, "The Hallicrafters Story".)

And does anyone have manuals and schematics for a Heathkit IG-72 audio generator and AT-1 transmitter, Hallicrafters S38E receiver, and Eico's 1078 ac power supply, 239 TVM, and Model 315 signal generator? Write before sending.

Robert Gagne
143 Millville St.
Salem NH 03079

I would like to hear from anyone who served at the Naval Radio Station NSS, Annapolis MD, from 1942 to 1946.

Laurence E. Hoepfer N7BJT
Box 334
Columbia Falls MT 59912

I need a schematic for a Hickok Model 19XD signal generator.

Sherman Banks N4CXF
Rt. 1 Youngs Mill Rd.
Kingston GA 30145

Has anyone interfaced an Atari 400/800 to a rig for sending and receiving CW? Is software available?

John S. Lee KA4EPR
12341 Dickinson Dr. W303
Coral Gables FL 33146

I am in need of information about the WWII Navy Model MBM radio.

Tony Grogan WA4MRR
5 Rollingwood Dr.
Taylors SC 29687

I would like to contact anyone who is using the Texas Instruments TI-99/4 home computer to send and receive RTTY, CW, and SSTV.

Miguel Binstok LU1DIU
PO Box 012592
Miami FL 33101

I would like to hear from owners of the code reader made by Microcraft. I need data on how well it works, QRM, etc.

Berand G. Kirschner WB0YCQ
1440 Grand Ave. #11
St. Paul MN 55105

I would like to "marry" my Johnson Invader 200/2000 with a receiver that has a 5.0-5.5-MHz vfo so that I get transceiver-type information. Can anyone help?

Arthur Ford W2HAE
552 Hillside Ct.
Melbourne FL 32935

I need a copy of the schematic for a Hallicrafters S-107 Mark II receiver, built approximately 1961.

Sheldon Daitch WA4MZZ
Box 8091
Greenville NC 27834

improve 73 and our other publications. With our mountains to climb, he could easily take off about fifty to seventy-five pounds and get into fighting trim to help amateur radio get back into a growth mode. What say there, Harry? I know he's always been a very big fan of mine, so let's see what happens.

WHAT'S THAT CLOUD?

Is that a nuclear blast cloud rising over New Hampshire? No, the work on our nuclear power generator seems to have been halted. A clipping sent in from a North Carolina paper (where they put much stock in these things) gives us a hint. It seems that there are more cigarettes per person sold in New Hampshire than in any other state. About 254.4 packs for every person. . . including the kids.

Now before you get the idea that my own efforts to stem the tide of smoking by not hiring smokers is totally ineffective, I should point out that New Hampshire has a lower tax on cigarettes than other states. The result is that Massachusetts (called taxachusetts) people come up here in swarms to buy cigarettes and liquor, both of which are a bargain in New Hampshire.

The gas stations along the border do a land-office business in cancerettes, helping substantially to stamp out life in the great commonwealth just south of us. Liquor is sold in state liquor stores, thus giving us a cut of the action towards lowering taxes. Indeed, we are the lowest taxes state, with no sales tax and no personal income tax.

The only serious problem we have is the air pollution along the Massachusetts border from all those cigarettes.

NO NEWS VS. GOOD NEWS

The recent purchase of *The Daily News* in New York brought back memories of my first visit to *The News*, back in 1938. When I visited *The News* along with my high school class (we often went on field trips to see businesses), little could I have imagined that in ten years I would be working for WPIX, *The News'* television station. Heck, in those days television was a new invention which was being shown at the New York World's Fair. The sets for receiving the few broadcasts were prohibitively priced. In 1938, I was just barely getting going in amateur radio, having been involved for about a year.

The Daily News plant was modern then, with new high-speed presses and row upon row of Linotype machines. The Linotype operators delighted my classmates by making up our names in type slugs and tossing them to us, burning our hands with the hot lead while they laughed.

Hitler was raising hell in Europe and war was brewing. Despite the barrage of propaganda, war was not real to us and it never even occurred to me that before long I might be going to war on a submarine in charge of maintaining and operating all of the complex electronic equipment.

After the war. . . and after college. . . having avoided entrapment by large corporations (a fate suffered by most college graduates which dooms them to mediocrity of income for life), I found myself in broadcasting. First I tried radio *engineering* and announcing. Then, when a spot opened at WPIX for an engineer, I made contact through an old friend Bob Sullivan, who worked as a feature writer for *The Sunday News*.

Bob, a friend of the family, had quite an influence on my life. It was he who introduced me to classical music when I was about seven. He also was a Gilbert and Sullivan nut, which I became, too. I maybe got even by exposing him to country and western, which took with him.

Before we could put WPIX (channel 11) on the air, we had to get some experience. In 1948, there were no unemployed television cameramen to hire. *The News* rented studio space a few blocks from their 42nd street skyscraper at Reeves Sound Studios. Buzz Reeves is reasonably well known today for his incredible contest station. I think they use the call N2AA. Buzz was one of the wealthy hams I talked with when I was looking to start *73 Magazine*. Wisely, he was not interested.

When the studios were finished in *The News* building, we moved to there and finished getting ready to go on the air. We learned to use the cameras, to fix them while operating, to handle the mike booms, and to cope with the various unions which have a vice-like control of New York. The inaugural ceremonies were in the lobby of the building, with me as the cameraman.

It didn't take long before I was nosing around the top floor of the skyscraper, looking for a place for a small ham station. I found an unused room and soon had permission to use it and put an antenna on the roof of the building. I brought up my SCR-522, which was state-of-the-art in those days. Imagine, crystal control! Twenty Watts! Then I put one of the Bill Hoisington (W2BV) 16-element beams up and found myself with a whale of a signal. I could work anything from central Connecticut on down almost to Philadelphia, including all of Long Island. I made thousands of contacts. Hams are still bringing my old *News* building QSL cards to hamfests to flash at me.

Being young and foolish (as differentiated from old and foolish), I wanted to put my beam in the best possible location on the roof of the building. I wanted it out in the open so that I would have a good signal in all directions. Well, the *only* really good place for it was mounted on top of a parapet. I have to admit that I was a bit shaky about climbing out on it to set up the rotator and beam. I had to skinny out about fifty feet, with a 25-story drop on one side and about six stories on the other. Just to help matters, it was windy. It is *always* windy on top of a 37-floor building.

My stint atop *The News* building had lasting repercussions. It was while operating from this aerie that I began wondering what those strange beedle-beedle signals were on the high end of the band. I started asking around and was led to John Williams W2BFD out in Woodside, Queens. John was playing around with radio Teletype®. Being an unrepentant experimenter, I was quickly hooked on RTTY.

John was the father of ham RTTY. He got a lot of us hooked on it in the late 40s. My downfall, if you like to think of it as that, came when I went to work for WXEL, a television station in Cleveland. I was hired on as a television producer and director. They had a mimeo machine, which was a fairly rare item in those days. Within a few days, I managed to get the first issue of a *RTTY Bulletin* out for the few hundred RTTY experimenters. I almost ruined the mimeo machine in the process, but I was started. The *Bulletin* grew into *Amateur Radio Frontiers* and kept going on almost a monthly basis until I became editor of CQ in January, 1955.

The News has changed remarkably little in the last thirty years, which probably is why it was recently put up for sale. The gradual closing of one New York paper after another, often in the wake of strikes, has kept the papers from making much money. That and union opposition kept *The News* from modernizing their equipment. I wouldn't be surprised if they still had some of those old Linotype machines being used to set hot slugs of type. I should get back for a visit and see if any of the old television crew are still there.

Bill Hoisington's fire tower eventually blew down in a storm and he found himself fired from the firm he had worked with for years. The main reason for letting him go seemed to be that he was getting too close to retirement pension age. He went into business writing a long series of simple VHF and UHF construction projects for 73. He moved to Peterborough (as K1CLL) to make this simpler. Following a divorce and some serious ill health, Bill moved to the Philippines and got remarried. He seems to be living happily ever after there, still working on simple home VHF projects.

You know, one of the odd things about operating from the top of a skyscraper or a mountain is that when the two-meter band begins to open, it is the stations on the ground which hear the skip signals first. I would hear New York stations working down into Virginia and North Carolina for an hour or more without being able to hear a whisper of the southern chaps. Then, when the DX was starting to work on up into Connecticut, I would start hearing them and be able to make contact. My elevation had little benefits for that type of contact. There *are* drawbacks to skyscrapers and mountains.

Well, I hope that the new owners of *The News* will modernize it and keep it going. I enjoyed my working there and will never forget the excitement of DXing from that spot.

DEALER DIRECTORY

Phoenix AZ

The Southwest's most progressive communications company stocking Kenwood, Icom, Yaesu, MFJ, B&W, Astron, Larsen, Cushcraft, Hy-Gain, Bearcat, and more. Would like to serve you! **Power Communications Corp., 1640 West Camelback Rd., Phoenix AZ 85015, 241-Watt.**

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Diego CA

We buy and sell Surplus Army Navy Electronic, also Terminated Material. What do you want to sell? Write for catalogue. **Electronictown, Inc., 440-7th Avenue, PO Box 2048, San Diego CA 92112, 232-9379.**

San Jose CA
SAN FRANCISCO BAY AREA

Homebrewers' haven; tons of new and used Ham/Computer gear and components. Serving Hams since 1958. We specialize in ICOM, KLM, Mirage, Comptronix. We ship worldwide. **Tele-Com Electronics, 15460 Union Avenue, San Jose CA 95124, 377-4479.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santee & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Smyrna GA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. **Britt's Two-Way Radio, 2506 N. Atlanta Rd., Smyrna GA 30080, 432-8006.**

Preston ID

Ross WB7BYZ, has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 478003, 238-1456.**

Littleton MA

The ham store of N.E. you can rely on. Kenwood, ICOM, Wilson, Yaesu, DenTron, KLM amps, B&W switches & wattmeters. Whistler radar detectors, Bearcat, Regency, antennas by Larsen, Wilson, Hustler, GAM. **TEL-COM Inc. Communications & Electronics. 675 Great Rd., Rt. 119, Littleton MA 01460, 486-3040.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, Dentron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104. 668-8696.**

Hudson NH

New England's Distributor and Authorized Service Center for all Major Amateur Lines. **Tufts Radio Electronics, Inc., 61 Lowell Road, Hudson NH 03051, 883-5005.**

Somerset NJ

New Jersey's only factory-authorized ICOM and YAESU distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873; 469-4599.**

Syracuse-Central NY

HAM-BONE RADIO SAVES US LOT OF $$$ on all Icom, Ten-Tec, Hygain & Kantronics Gear. Fast, Dependable Service Before & After the Sale! Service is Our Main Business! Need Cash-Ham-Bone will sell your gear for 10% commission. 3206 Erie Blvd. E., Syracuse 13214, 446-2266.

Philadelphia PA/ Camden NJ

Waveguide & Coaxial Microwave Components & Equipment. Laboratory Grade Test Instruments, Power Supplies, Buy, Sell & Trade all popular makes—HP, GR, FXR, ESI, Sorensen, Singer, etc. **Lectronic Research Labs, 1423 Ferry Ave., Camden NJ 08104, 541-4200.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Syracuse-Rome-Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 337-0203.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Bend OR

Satellite TV. Known brands. Call today for more information and inquire about our dealer program. **WESPERCOM, P.O. Box 7226, Bend OR 97708, 389-0996.**

Scranton PA

ICOM, Bird, CushCraft, Beckman, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, CDE, AEA, Vibroplex, Ham-Key, CES, Amphenol, Sony, Fanon/Courier, B&W, Ameco, Shure. **LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.**

Dallas TX

Dealer in Used Computer Hardware & Electronic Parts. Special on Daisy Wheel Printers. Xerox Word Processing Equipment, Dual Card Printers and Display Systems. Catalog $1.00. **Rondure Company (The Computer Room) Dept. 73, 2522 Butler St., Dallas, TX 75235, 630-4621.**

San Antonio TX

Amateur, Commercial 2-say. Selling Antenna Specialists, Avanti, Azden, Bird, Hy-gain, Standard, Vibroplex, Midland, Henry, CushCraft, Dielectric, Hustler, ICOM, MFJ, Nye, Shure, Cubic, Tempo, Ten-Tec and others. **Appliance & Equipment Co., Inc. 2317 Vance Jackson Road, San Antonio TX 78213, 938-3350.**

Vienna VA

The Washington metropolitan area's leading supplier of the latest in Amateur Radio and Test Equipment. On your next trip to the Nation's Capital, stop by and see us. **Electronic Equipment Bank, Inc., 516 Mill St. N.E., Vienna VA 22180, 938-3350.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the August '82 issue must be in our hands by June 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DAYTON '82

It isn't just the flea market with over 500 small entrepreneurs selling out of their trucks, campers, and cars. It isn't the nearly 200 exhibitors inside the rambling Wampler's arena. It isn't the 25,000 or so hams and their families which descend upon Dayton in April every year. Pandemonium.

Whenever I hear about some hamfest or a computer show pulling 20,000, I think of what it takes to handle the crowds at Dayton and how many people this really is all in one area. The fields are packed with cars for a half mile or so around the arena area. The cavernous arena buildings are packed with people. No matter how many there are inside, it seems as If the flea market area outside is still so busy that it is difficult to get around.

Dayton attracts average hams from several nearby states. But more than that, most of the real "movers" of the hobby. . . the hams who are doing the building, the inventing, the pioneering. . . come from everywhere in the country. These are the hams who make amateur radio the incredible hobby that it is.

Other hamfests may have technical sessions, but these are attended by merely interested amateurs. At Dayton, the attendance of these tech sessions is made up of the hams who are doing things. Here, one gets to say hello to the top DXers, the DXpeditioners, the slow-scan three-dimensional color experimenters, the packet switching fanatics, and the spread-spectrum aficionados.

While several of the other larger hamfests have gone to rather great lengths to bring in computer-oriented exhibitors, Dayton has maintained a straight ham approach which has kept this field of ham activity at a relatively low profile. Yet this year, when we counted the exhibits, we found that about 15% of them were computer-oriented. This is low, of course, compared to the computer interest in the ham world. Our most recent survey of the *73* readership showed that the ownership of microcomputers is up to 39% now. In another year perhaps 50% of the readers will have microcomputers.

I tried to give a talk during the hamfest, but the meeting "room" was so terrible that I gave up. The temperature was well into the sleep zone and the noise was such that someone three feet away had trouble hearing what was going on. The area was just one part of a huge building, with deafening noise coming from all sides. I don't think I'll try that again. I'll bet it was 90° or more in the room, with only enough seats for about 70% of those who came to hear me.

My talks are generally rather low key, with some time required for the humor to come through. I do speak about serious things, but I don't take many of them seriously. And I don't do well when I have to communicate by yelling at people.

I'll no doubt continue to go to Dayton, but only to say hello, find out what's new, and get together with my friends in the industry.

HARRY, WHERE *ARE* YOU?

Missing for the first time in years at Dayton was the flushed cherubic face of Harry Dannals. I, for one, am sorry to see good old Harry go. And I have to admit that I was darned upset when I learned that the ARRL board just plain outright dumped him. Now what would it have cost them to be nice about it and give him a President Emeritus position?

Dick Baldwin, also not visible at Dayton, seems to have fallen in the same black hole now occupied by Harry, but at least with a face-saving title to make it look better. That's what they did with John Huntoon when the power politics at HQ dumped him a few years ago. Anyone remember John?

You know, one of the surprises I got when I went around to visit some wealthy hams back in 1960 had to do with Dick Baldwin. I'd been fired by *CQ* as editor and had this crazy idea of starting my own ham magazine. I was hoping to find a ham with enough money to get a new magazine started. One chap I visited said he thought the idea was a good one, but that it was too dependent upon just one person: me. He was right about that, of course. He also mentioned that Dick had been around with a similar proposition a few days before.

I dropped Dick a note asking if he might be interested in a joint venture. He wrote back saying no. Well, I went ahead without any financing and Dick never did. Oh, it was nip and tuck for several years, particularly when the ham business fell to pieces after the 1963 ARRL proposal for changing the licensing structure back to the 1930s form. That's when we lost 85% of the sales of ham gear in just one year and all of the major manufacturers were forced out of the industry.

The ten years after that of no growth were hard ones for me and *73*. It wasn't until I managed to sell the idea of FM and repeaters that the industry (and *73*) turned around.

Harry, who had retired from his job at Sperry in order to be available for the General Manager's position, may have to unretire. I wonder what went wrong for him? I'm told by the ARRL insiders that he performed the most exhaustive campaign for the job in history. . . at League expense. Perhaps it was his bitter opposition to having a woman on the board. Well, no matter . . . Harry is well out of the rat race and the demands of the ARRL presidency. I was worried that the even greater pressures of being General Manager might be too much for him. Perhaps he can relax now and add at least twenty years to his life. This may be the best thing that has happened to Harry in years. . . instead of the disaster which it first appears.

INSTANT LICENSES

At long last a solution to the code exam has been effected. Now it is no longer necessary

VOLUNTEERS NEEDED

How would you like to be on the "inside" of a major amateur radio contest? Here's your chance!

We're looking for volunteers to become members of the *73 Magazine* Contest Committee. Anyone with an interest in contesting and a willingness to work hard is welcome. Committee members will help with the following:

1. Contest rules and ethics.
2. Forms and correspondence.
3. Log checking and scoring.
4. Filling out and mailing awards.

Heading up the Contest Committee is Bill KE7C. Please drop Bill a note (with SASE) and let him know where you can help. Write to Bill Gosney KE7C, *73* Contest Committee, 2665 North Busby Road, Oak Harbor WA 98277.

We want *you* on the *73* Contest Team!

for anyone to bother to learn even one single character of the Morse code to get a ham license. The solution to the code problem is so simple I'm amazed that no one ever thought of it before. Once you get the concept, you see that we no longer have to argue about the code.

At Dayton someone was selling a cassette with the FCC code test on it. With today's miniature cassette recorders it is a snap to have one in your pocket and record the tests as they are being given. Well, someone did this and was selling the tapes at Dayton. Once you have that all you have to do is get someone to translate it for you, memorize the short text, and present yourself for the test.

The FCC is so underpowered these days that they really don't have the personnel to devise a lot of different tests. I'll bet that at best they have maybe two for Morse code, if that many. There are no indications that the Commission is going to get more money from Congress, so it is unlikely that there will be much doing in the way of changes.

So, by the time you put the Bash books together with a cassette of the code test, you have a ham license that anyone who can read and write can get. No more is there a need for that tedious learning of the code. No more struggling with theory or the rules. Bash gives you the answers to the written exam and the code cassette solves that problem.

Who will be the first Extra to get licensed with no ham knowledge whatever? Or perhaps I should ask, who *was* the first?

As a humorous side note: the FCC recently was handed a code test exam which was 100% perfect. Well, perhaps *almost* perfect. You see the answers were perfect for the *other* test...not the one given.

FCC DELETES 97.71 AND 97.74

"Unenforceable, burdensome and unnecessary" is how the FCC described 97.74, a rule requiring amateurs "to provide for measuring the station's emitted carrier frequency and to establish procedures for independently checking it regularly." In their April 1 meeting, the commissioners voted to delete 97.74 and 97.71, a rule which required transmitters operating below 144 MHz to have adequately-filtered plate power supplies. In deleting 97.71, the Commission said "the rule itself is inappropriate and outmoded."

WE NEED KIDS

With all due respect to Bash and his one-day blitz cram courses, at $175 for one day it is unlikely that we are going to get many kids into the hobby via this mercenary system.

Now, I have the greatest admiration for Bash and his bid to outdo Don Miller in making money out of amateur radio. I'm sure he will find no shortage of well-to-do hams who want to get a higher license without having to learn one bit of theory. Just ten of his weekend sessions a year should net him around $150,000. One really has to admire that, no matter what the consequences to the hobby.

His system is simple and it works. He sits you down for a full day of memorizing the answers to the questions. He has you write down the answers you are going to need the following day on the exam...write 'em two or three times to make sure they are well-established in your short-term memory. As an aspiring General or Advanced, you can't lose. Neither can Bash.

All this has absolutely nothing to do with the major crisis in amateur radio: the need for new hams. Novices...teenagers. We already have all of the old men we need in amateur radio—now what we need is to see about 100,000 new Novices per year to get our rusty old hobby jumping again. That would spur technical developments and building (kids really love to build) and get some life into things.

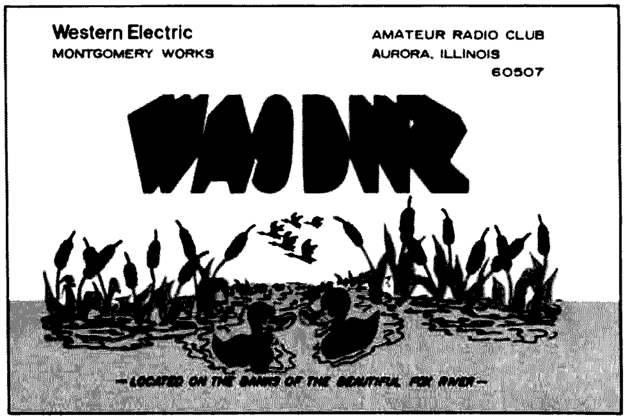
What has your club done to get a ham group started in the local high school? If we don't even give the kids a chance to be exposed to amateur radio, we have no gripe when they turn to drugs, drinking, getting into car accidents, malicious destruction, spray painting everything in sight, and getting all of your girls pregnant. At least give them an alternative!

NAVASSA TIME

The May 3rd issue of *Time* had a nice article on the recent hamming of Navassa Island. As one of the few persistent (stupid) enough to go there twice, I read the item with more than average interest.

The first trip, in 1958 (KC4AF...a call now held by a chap in Alabama), saw six of us chartering a motor-sailer in Nassau and making our way down the Bahamas to Haiti through a heavy storm. We just barely missed crashing on a reef when we got to Haiti before dawn. It was a hell of a trip and we found ourselves about 50 miles off course by the time we

Continued on page 118



QSL OF THE MONTH: WA9DNZ

The natural theme of the Western Electric Montgomery Works club station comes from the plant's location on the Fox River. Built on the site of a former amusement park, the factory is in a wooded setting and sports a year-round duck population. The card's bright colors are sure to catch the eye of the operator on the other end.

Log of the Colorado Queen

—wet, wild Field Day fun

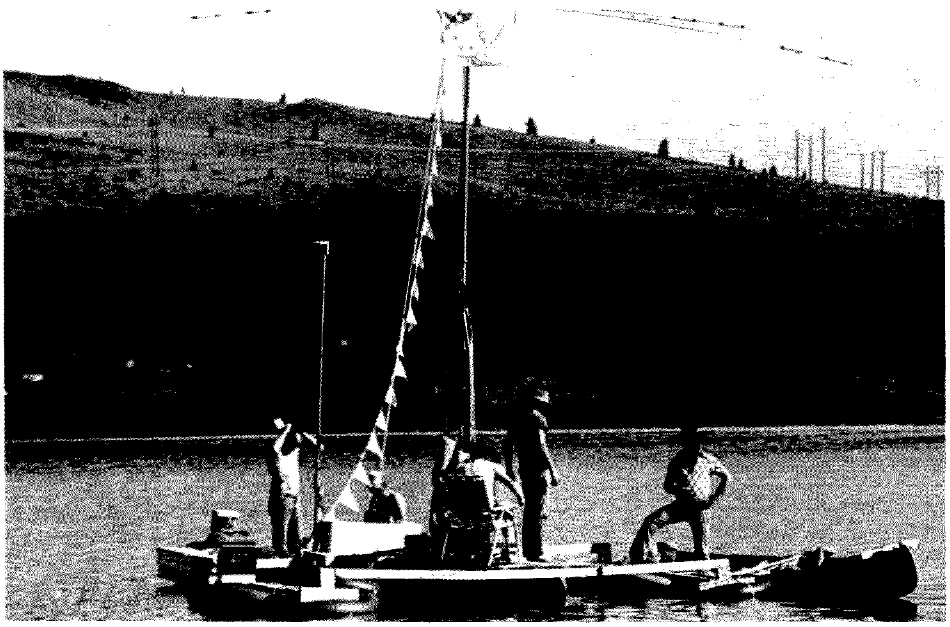
F. Dale Williams K3PUR
5592 S. Moore Street
Littleton CO 80127

Spring, as reflected in the short-lived green sheen of the foothills, was well settled in the Rocky Mountains when the members of a Denver area amateur radio club gathered to discuss the 1978 Field Day activities. The interests of the club had varied over the years, but the recent increased appeal of contesting and the technical antenna expertise promised in the form of a full-size 40-meter beam to help fill in the propagation holes in 10-20 meters convinced the membership to go all out for top spot in the Field Day results.

Without debating the good and bad points of Field Day, suffice it to say that participation can be divided into two broad classifications—high key and low key. Those groups scoring high obviously are in the high-key category which describes the organization, planning, and pressure required. The pursuit of a hobby is supposed to be fun and the belief that a sense of personal accomplishment could be achieved without the peer pressures for maximum contacts led to the breakaway, following the 1978 Field Day activities, of five members of the club who subsequently formed "the crew."

When the crew, consisting of Al NØAUS, Pete N6EBC (ex-WDØBJY), Gary WDØGGL, Glen WDØFEO, and Dave WB8KYP, meets, they have only two goals: having fun and planning technical projects which some people say can't be done. It was this attitude that prevailed at the first meeting of the group where plans were formed to construct a floating all-band station. Once the concept was agreed upon, it became obvious that this vessel would require a name befitting its heritage. Since NØAUS had a thing for the *African Queen*, having seen the movie more times than he could remember, it wasn't long before the group came up with some apropos phonetics and a name: CQ, the *Colorado Queen*.

During the winter, plans for a 1979 summer launching were made with reckless abandon and much beer. Chatfield Reservoir, south of Denver, at an elevation of 5432 feet, was chosen as the site of operations and WDØFEO offered the use of his 10-man white-water rubber raft as the ship of destiny. As might be expected, the selection of a suitable antenna and how to mount it to a rubber raft were the biggest problems. The final solution involved a 14AVQ all-band vertical, owned by WDØFEO, and a floating platform. A hollow steel pipe and flange were attached to the center of a large diameter circular section of plywood through which a hole had been drilled in the center. Three 900 x 16 truck inner tubes were mounted under the platform to provide flotation and stability; three outriggers, emanating from the



The crew and the Colorado Queen *preparing to begin the weekend operations.*

WB8KYP readies the triband beam for a little more height.

The backup Kenwood, unloaded by WDØFEO, provided flawless operation.

platform and made from 2 x 4 x 12s, supplied guy points for the vertical which was attached to the pipe. A long cable connected to and extending through the center of the pipe into the water served as system ground. Support framework for the equipment and personal gear was ably constructed through the experience of WDØFEO and the crew's labor.

Now consider, for a moment, a 14-foot rubber raft powered by a 3.5-horsepower motor towing the antenna platform just described with the vertical via a 30-foot rope. While underway, the floating antenna platform maintains its distance, but when the raft is stationary, the weight of the rope and coax connecting the rig on the raft to the antenna tend to draw the platform closer as the cable sinks into the water. A number of four-inch styrofoam balls, with a hole cut through the center for the coax, solved this problem and prepared the *Queen* for her August 18th inaugural voyage.

With a Yaesu FT-101EE powered by two paralleled lead-acid batteries, various 2-meter hand-helds, assorted swr meters, and other gear on board and an appropriate christening with white lightning, the historical launching of the first mile-high freshwater mobile took place amidst the curious gazes of swimmers, boaters, and sunbathers. During the weekend of operation, many contacts were made, lots of time was spent ragchewing as opposed to exchanging callsign, signal strength, contest number and best wishes, and most important of all, a fun time was had by all, including WB8KYP who towed a stranded cabin cruiser back to shore with his "shuttle canoe" and paddle power. The only casualties, other than operator sunburn, on this first voyage were a waterlogged 2-meter hand-held and damp finals in the FT-101EE.

It is a well-known fact that the higher the antenna, the better the communications. Therefore, Green Mountain Reservoir, at an elevation of 8200 feet, was chosen by the crew for the 1980 launching of the *Colorado Queen*. Besides that, WDØFEO offered the use of the family cabin for a weekend of revelry. The same basic raft and antenna platform were used with some extra framing and plywood floor added to the raft for rigidity and the addition of equipment boxes to preclude some of the water problems encountered the previous year.

After a successful launching and an uneventful morning of operation, the crew was languishing on the deck, contemplating the relative merits of Coors beer, better known as Colorado Kool-Aid, when the capricious mountain weather made one of its abrupt changes. In less time than it takes to QRX, the sun disappeared and 70-mile-per-hour winds whipped the surface of the water into a rough pattern of whitecaps. Since the closest land was in the form of an island, the crew cranked up the 3.5 pony-power engine and headed the *Queen* for the leeward side. The

bamboo mast supporting WDØFEO's 2-meter beam split with a resounding crack and the antenna was fished out of the drink by means of the still attached coax.

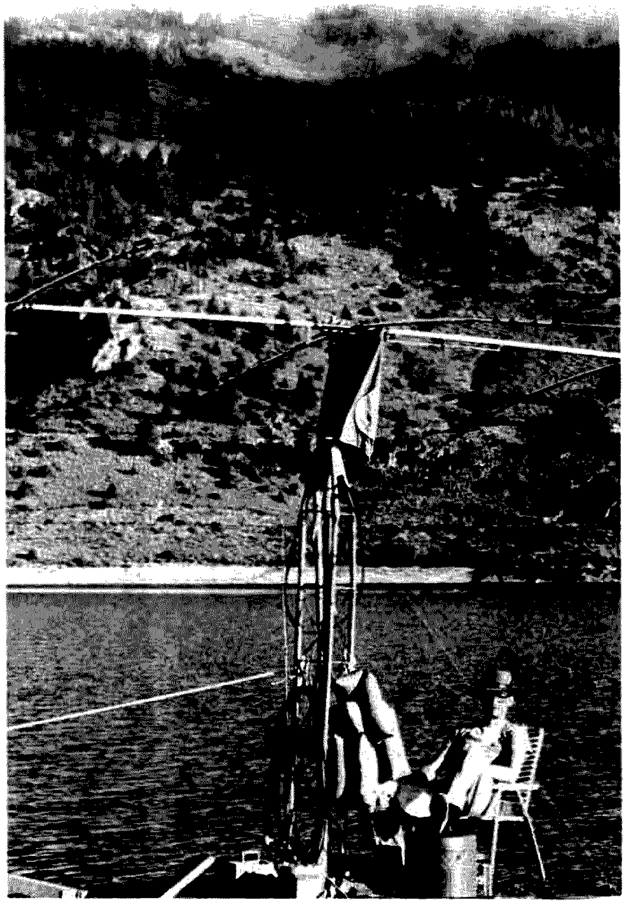
When the island was finally reached, everyone disembarked to attempt to find some shelter. It was a short time later when it was discovered that no one had dropped anchor or tied up the raft, which was now making good time away from the island. Luckily, the shuttle canoe was still on the shore and the chase began. In the ensuing recovery, to add insult to injury, WDØFEO's ten-gallon hat was blown into the water where it promptly sank beneath the waves. Repeated efforts to recover this well-worn relic were all in vain, although WB8KYP swears he saw a catfish wearing something similar as it jumped in front of the raft.

No sooner was the raft secured back at the island than some crew members decided that the original cargo of three cases of beer was fast being depleted and some suntan lotion to soothe the morning's ultraviolet onslaught was in order. What is it they say about discretion being the better part of valor? Anyway, WDØGGL and WB8KYP volunteered to take the canoe and attempt to refurbish the supplies. In an adventure about which the residents along the shoreline still chuckle, these two stalwarts paddled and bailed their way to the far shore, in the only vessel on the water, oblivious to the binocular-equipped audience watching from the many windows on land. Reportedly, the trip back to the island after obtaining the necessary replenishments was much easier with the wind at the rear. Sunday dawned bright and clear, providing a fine atmosphere for the conclusion of that year's freshwater operation with only a Yaesu 2-meter rig sustaining water damage and WB8KYP once again coming to the rescue of a stranded cabin cruiser, but this time he was prepared (?) with a 1.7-horsepower Neptune engine mounted on his shuttle canoe.

By 1981, the crew was looking for bigger and better challenges to conquer with the *Colorado Queen* and had made the operation an annual event taking place the weekend following the July 4th holidays. Commensurate with the arrival of spring, the crew, minus N6EBC who had been transferred to California, gathered to begin construction of the latest version of the *Colorado Queen*.

Over the winter months a new design for the antenna platform had evolved, made necessary by the decision to use WB8KYP's TH-3Jr. triband beam. WDØFEO had managed to find a small boat dock which had four 50-gallon drums attached underneath for flotation and steel-rimmed wheels mounted on the sides for easy water entry and exit. Six 900 x 16 truck inner tubes were added for stability and two 2 x 4s for attaching the floating dock to the framework of the raft. Three holes drilled at the center of the dock allowed the mounting of a steel tower section which was guyed to the four corners of the dock superstructure. The mast was then slipped through the tower pipe and the triband beam mounted on top. Enough mast was used to allow the antenna to be raised between six and fifteen feet and still offer the capability of armstrong rotation.

The first test of this water mobile antenna barge almost drowned two of the crew due to its top-heavy attitude. Subsequently, an exercise with a local firm's Computer Aided Design equipment showed that a 180-pound counterweight suspended nine feet below the water line would stabilize the platform. Oh, the wonders of modern technology. The counterweight was constructed and made adjustable so that it could be raised when approaching the shore or lowered to 14 feet for windy conditions.



WDØGGL relaxes as the sun tries to burn off the early morning mountain mist.

As the weekend of July 11-12 drew closer, construction activity intensified. Boxes to hold the lead-acid batteries were built, a bracket assembly to provide mounting of the 14AVQ to the raft frame for 40- and 80-meter operation was completed, and white paint flowed freely.

By the time launch day 1981 arrived, the crew had put in at least 480 man hours in labor alone. The arrival in Denver of N6EBC a few days prior to the weekend signalled the imminent packup and departure of the crew for the mountains. Assembly of all the miscellaneous parts, all prepared and marked beforehand, took about two hours on Friday.

Meanwhile, N6EBC had brought along some Santa Maria beans from California which he put in a borrowed enamel pot, then adding some "miscellaneous condiments" before placing them on the gas-modified woodstove to cook. I have been known to prepare some pretty bad-looking vittles, but I have never seen anything eat the enamel off the inside of the pot like those beans did. Thank goodness the sirloin roasts with the secret flavoring, barbecued over an open oak fire, were really good.

Bright and early Saturday morning, the rigs and equipment were loaded into the raft and hooked up and the third annual launching of the *Colorado Queen* became history—or so it was

supposed to be. Output power from the Yaesu FT-101B was almost nil and the LEDs on the front of the Icom 2-meter rig would not even glimmer. Power connections were checked and rigs exchanged without success. Finally someone got the bright idea of measuring the voltage of the batteries. Eureka, a brand new heavy-duty battery had a shorted cell and was pulling the parallel battery combination down to about 8.5 volts. The extra drain on the good battery limited current capacity for the day's operation, even after the bad battery was replaced.

Late Saturday afternoon some clouds moved in and the wind picked up, causing a slightly earlier than usual beaching of the *Queen* for the first day. A Kenwood TS-520S was put in service Sunday morning but the skip was not too long, with most of the QSOs originating out of the eighth call area.

From the operating position, N6EBC and N0AUS divide their activities between testing 807s and logging contacts.

Shortly before noon on Sunday, the clouds and wind returned from the opposite direction and the smell of ozone in the atmosphere indicated a high level of static electricity. As WD0FEO guided the floating station into the dock, the static build-up became so bad that a humming and discharge clicking were clearly audible, but the antennas were grounded and the equipment was removed without incident. Despite these technical problems, poor band conditions, high wakes from power boats pulling water skiers (which made the triband elements flap through a three-foot arc), and the many visitors that WB8KYP shuttled back and forth in his canoe, the two days of freshwater mobile operation, gourmet food, and 14 cases of beer made for an unsurpassed weekend of camaraderie and enjoyment.

What will the crew do for an encore? Well, plans are already underway for the construction of a motorized dock large enough for the TH-3Jr. at 30 feet, the 14AVQ vertical, a 2-meter mast and five-eighths groundplane, a gasoline generator, a Model 35 Teletype, three operating positions, and many creature comforts. When not in use, the dock will serve its normal purpose.

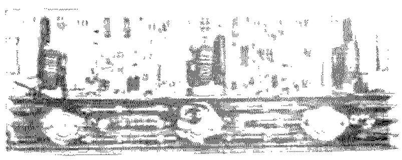
If you didn't manage to get your call letters entered into the log of the *Colorado Queen* for 1981, you missed the opportunity of receiving a fine 8 x 10 color picture QSL card. Mark your calendar now for July 10-11, 1982—the crew will be listening for you. ■

• BEC • Bullet Electronics Corp. P.O. Box 401244E Garland, TX. 75040 (214) 278-3553

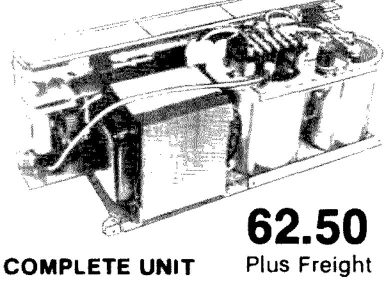
THE PRESIDENT SAYS: "HOGWASH!!"

After taking one look at the TRIPUT POWER SUPPLY our engineer declared that the units were worth several hundred dollars each. He pointed out the engineering, high quality construction and state-of-the-art integrated design in support of his position. The President of **BEC** more pragmatically pointed out the already full warehouse and the two trailer truck loads of power supplies waiting in the parking lot, and set the price to move them **QUICKLY!** We have a large quantity, but the supply won't last long. The only thing we ask is *please* read the ordering rules.

QUALITY DOUBLE SIOED GLASS BOARD



REGULATOR ASSEMBLY
(part of unit)



COMPLETE UNIT
(as you receive it)

62.50
Plus Freight
21 lbs.
6 x 5¼ x 12

3 OUTPUTS
12V @ 8A (12A Int.)
5V @ 10A
-12V @ 5A

INPUT 105 - 125VAC

- UNIT IS COMPLETELY ASSEMBLED!
- Fused primary and DC sections
- HUGE SHIELDED TRANSFORMER
- 2% Load & Line Regulation
- Low Ripple (100mv)
- Short Circuit Protection
- Overvoltage Protection on all three outputs
- 25A Bridge Rectifier
- Over 60,000 mfd of filters
- High Efficiency **Switching Regulator** reduces heatsink area
- Schematics and service guide included
- Thermal Shutdown
- Statis LED's (3)

ORDERING RULES

1. Mail check or MO for $62.50 + $5.00 for shipping or phone (214) 278-3553 to charge VISA/MC or COD order. (UPS COD only, add $2.50 COD fee)
2. Texas residents include 5% sales tax.
3. Orders for this unit will be shipped within **48 HOURS** or we pay the freight! (*weekends or holidays excluded*)
4. **ONE TIME OFFER! LIMIT TWO (2) SUPPLIES PER CUSTOMER.**

CB to CW?

—converting the Hy-Gain board

Photos by W1GSL

Operator's view of the transceiver. Note the insulating washers around the key and phone jacks. The internal dc power ground is floated from the cabinet to permit use of an external supply of either polarity. Front panel is 7″ × 4″.

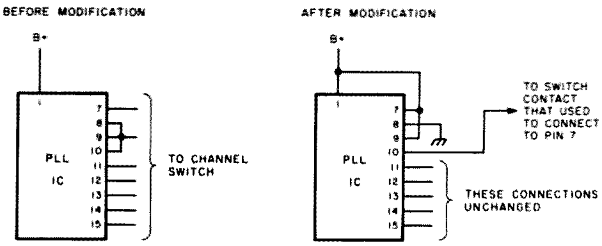

Fig. 1. Channel selector modification.

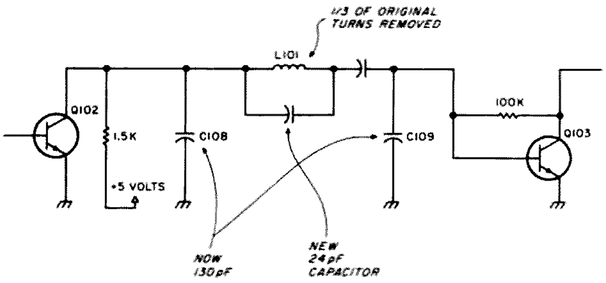

Fig. 2. Modifications to increase bandwidth of low-pass filter.

If you're one of the thousands of hams who bought one of those Hy-Gain CB set printed circuit boards for a song when they appeared on the surplus market, then this may be the article you've been waiting for. Described here is a neat little ten-meter CW rig that boasts a feature you won't get in the standard HF transceiver: full break-in. The rig is built around the Hy-Gain board and is inexpensive to duplicate. You don't have to buy any new crystals or exotic ICs; in fact, the design philosophy has been to add nothing which couldn't be found at the local Radio Shack outlet. If your junk box contains a few old transistor radios and a twelve-volt power source, you shouldn't have to buy anything at all.

Before getting into the actual conversion steps, let's review what we have and where we're taking it. The circuit boards on the surplus market were destined to go into a whole family of Hy-Gain sets (models 2679, 2680, 2681, and 2683, at least). The receiver is a dual-conversion superhet with i-fs at 10.7 and .455 MHz. The transmitter is AM with an output between 3.5 and 6 Watts depending on individual transistor characteristics and the supply voltage. The heart of the frequency-determining scheme is a PLL-02A phase-locked loop chip, and it is possible to put the rig on ten meters by rearranging the wiring of the channel selector switch and modifying some of the other loop components. The theory behind the means of changing the frequency coverage is described in my earlier article ("CB to 10," *73 Magazine*, September, 1980) in more detail than I will go into here. I strongly suggest that you get and study that earlier article along with a circuit diagram of the board (I use the Sams Photofact folder covering the Hy-Gain model 2679A) before you start this project. The modifications aren't difficult, but I won't repeat here large sections of the earlier article. The modifications described here are given in three stages. First, the basic conversion to CW on ten meters: the frequency change, the bfo, fine tuning, and putting the transmitter on CW. Second are some convenience features: sidetone oscillator, detector modifications, rf/i-f gain control, transmitter frequency offset, and an active audio filter. The final stage is the modification to give full break-in. There are a lot of circuit changes involved in the complete conversion and I strongly suggest that you make and try them out one at a time. Troubleshooting a problem can be fairly easy when you know that it must be due to those last five wires you moved. A lot more time and test equipment will be needed if the set is silent and the cause could lurk in any of a half dozen modified areas. There are a lot of circuit changes involved in the complete conversion but most can be made and tested a few at a time.

A complete "road map" of the conversion is shown in Fig. 16 where a block diagram of the transceiver shows how the various steps fit into the big picture. For a starting point, it is assumed that your board is checked out and working as designed on 11 meters.

Several last precautions are in order before getting down to circuit details. Hy-Gain made a lot of these boards in many different varieties. Many have open areas on the circuit board which when filled with components add features like the i-f noise blanker. Don't worry too much about the missing components, but if you are given a choice, take the board with the most parts in it.

There are two different audio amplifier ICs in the sets I have seen: the pin-out and circuit are different, so you should watch out for that. Some boards were made to have the channel switch solder directly to the board, while others had posts for wire leads—this is a minor matter, but something you may have to allow for.

There is one crucial dif-

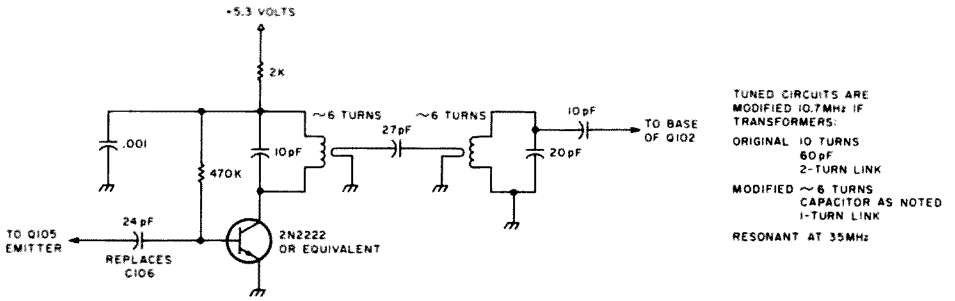

Fig. 3. Tripler schematic diagram.

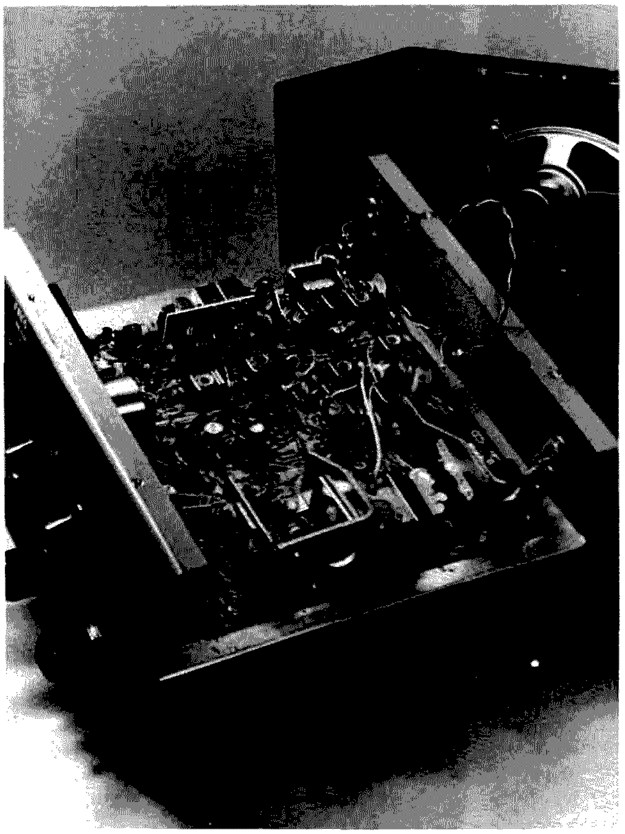

Interior view. Note the tripler board and the active filter board mounted upright from the main circuit board. Also shown is the method of mounting the speaker inside the top cover.

ference between the boards presently available—the PLL IC sometimes has 16 leads and sometimes has 18. The 16-pin packages may have one of several type numbers, but all are similar to the PLL-02A and can be converted as described in this (and the earlier) article. The 18-pin PLL IC is a dead end. These boards were destined to go in the Hy-Gain 16, a uP-controlled trunk mount model with a fancy calculator-like microphone/control unit. The PC card communicated with that unit via a serial data bus controlled in part by extra circuits inside the 18-pin PLL IC. Those boards cannot be converted as described here. If you have one of those boards, your best bet is to get the microphone and interface card that go with the main board and put it on 10 by changing the 11.806-MHz crystal.

Stage One—The Basic CW Conversion

The first and biggest step in modifying the rig is getting the operating frequency to ten meters. The conversion of the phase-locked loop requires three main steps: changing the programming of the loop divider, increasing the passband of the low-pass filter following the loop mixer, and adding a frequency tripler between the 11.806-MHz crystal oscillator and the loop mixer. Changing the loop frequency programming is the easiest step of the three. The PLL-02A chip contains a nine-stage binary divider which, along with the 10-kHz reference derived from the 10.240-MHz oscillator, sets the loop operating frequency. The divider is switched by changing the dc levels on pins 7 through 15. A logic one (5 volts) on a particular pin will enable the division controlled by that pin. All nine control pins are manipulated by the channel switch so that for channel 1 the overall division is 224 while on channel 40 the division is 268. The plan is to change this switch coding and therefore the operating frequency.

For example, note that since channel 1 is on 26.965 MHz and the steps are 10 kHz apart, we could move channel 1 to 28.005 MHz if we could change the divisor code to correspond to 328 on that channel instead of 224. Unfortunately, we can't make completely arbitrary changes in the divisor size because we are stuck with the channel switch and the code built into it. However, it is possible to reroute the connections between the switch and the PLL chip so that channel 1 moves up 960 kHz to 27.925 MHz. This means that channel 8 will then fall on 28.015 MHz and channel 40 on 28.365 MHz. The bulk of ten-meter CW activity takes place in the lower 200 kHz of the band, so the seven lower channels won't really be missed.

Now for the actual wiring changes. The schematic of the change is shown in Fig. 1. First cut apart pins 8, 9, and 10 of the IC on the circuit board foil. Pin 7 is disconnected from the channel switch and connected to +5 volts at pin 1, and the same is done for pin 9. Pin 8 is grounded and pin 10 is connected to the switch terminal that used to go to pin 7. That's all there is to the channel selector modification.

The frequencies for the new channels are given in Table 1 along with the appropriate phase-locked loop coding. The logic 1 level corresponds to 5 volts, while the 0 is ground, and you will want to run down the IC pins with a voltmeter to verify that the correct code for a particular channel actually shows up. There are several types of 40-channel switches sold for use with this board and it is easy to get confused about where the 5 volts goes in and the various IC pin connections come out.

Notice that the 10-meter channels, like the CB channels, are 10 kHz apart but that some frequencies are skipped and others are out of order. Be careful of the

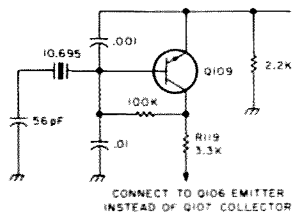

Fig. 4. The bfo, Q109, is supplied power constantly from Q106 instead of only during transmit.

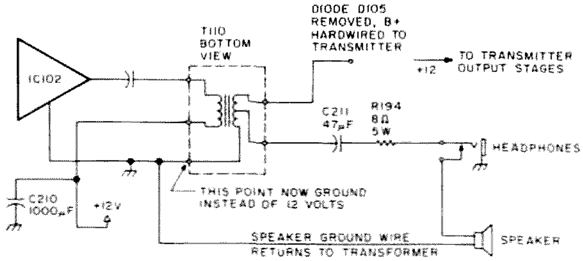

Fig. 5. Changes to audio output stage. The modulator is disabled by the removal of D105 and the speaker circuit is now operated at ground potential.

band edges, particularly if you're a Novice and especially after the fine-tuning modification is added.

The next step is to change the passband of the low-pass filter between the loop mixer, Q102, and the mixer buffer, Q103. This modification is necessary because the highest frequency passing through this filter is now 3.64 MHz instead of 2.68 MHz. The circuit changes, shown in Fig. 2 are straightforward. C108 and C109 are reduced from 330 to 130 pF, about one-third of the turns are removed from L101, and the inductor is paralleled by a 24-pF capacitor. These changes are fairly non-critical; the set described in the earlier article used 180-pF capacitors, half the turns on L101, and 82 pF in parallel with the coil. The values shown in Fig. 2 work fine, but if you have some capacitors that are slightly larger, don't be afraid to try them.

The final and probably most complex change is the addition of the tripler following the 11.806-MHz oscillator. The mixer input is really looking for the third harmonic of that frequency, but the Hy-Gain designers were able to save a stage by letting the mixer do the frequency multiplication as well as the mixing function. That trick doesn't work as well for us because the loop operating frequencies are shifted enough that some of the spurious mixer products cause trouble. As explained in the previous article, these spurious products can actually prevent lock on frequencies higher in the ten-meter band. The CW end of the band is close enough to the CB frequencies that the loop will lock without the tripler addition, but I found that the fine-tuning modification (described later) would not function properly. The frequency would shift all right, but over a portion of the shift range an unwanted beat note would appear in the mixer output. This beat would cause FM on both the transmitted and received signals. The tripler completely cured the problem, but you may elect to first get the loop running without that added complication as an easy means of verifying the other PLL modifications. By all means do add the tripler before getting on the air, or be prepared to get a lot of reports of hum on your signal (and don't be fooled, as I was at first, by looking at your output envelope and seeing no modulation—it sounds like AM hum, but being FM won't show on a scope.

The tripler schematic shown in Fig. 3 is simpler than the one described in the first article, but works just as well. A single stage multiplies the 11.806-MHz signal and two lightly coupled tuned circuits select out the 35.4-MHz signal. The tuned circuits used in this version are 10.7-MHz i-f transformers modified by the removal of half the turns on the core and replacement of the 55-pF stock capacitors with 20-pF units. Some experimentation may be necessary to get the circuits resonant at 35 MHz, and a good grid-dip meter is an invaluable aid. There are other techniques which would work well. For example, if you're really well equipped, you could use a variable frequency signal source and a high bandwidth oscilloscope. Of course, you can use any other type of tuned circuit—whatever the junk box has as long as it fits into the space available.

As shown in the photographs, I built the circuit on a small scrap of printed circuit board and supported it by the stiff leads used to supply power and signals to the board. This isn't the most mechanically rugged technique, but it is neat and with careful placement of the support leads is strong enough to be reliable. I reinforced the wires where they entered the main circuit board with a small drop of epoxy cement so that the stress would not be on the thin circuit foil below the board.

Once these circuit modifications are made, the loop can be adjusted for proper operation. Monitor the dc voltage on the positive side of C115 and adjust the vco slug (T101) so that the voltage varies from a low of around a volt on channel 1 to a high of about two volts on channel 40. The voltage should change slightly each time the channel switch is advanced. This voltage is a measure of the driving force necessary to pull the vco from its free-running frequency (set by T101) to the frequency requested by the channel selector; in fact, a meter inserted at this point could be calibrated to

*These frequencies are in the Novice segment.

All frequencies given are nominal and may vary ±5 kHz or so if you include the fine-tuning modification.

Table 1. New channel frequencies and PLL coding.

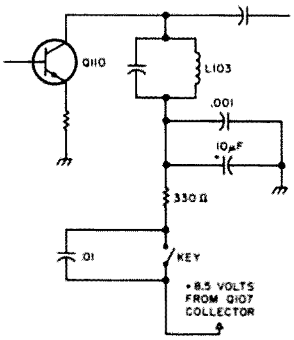

Fig. 6. Circuit modification to allow transmitter keying at the transmitter mixer, Q110.

read the ten-meter operating frequency.

Knowing this, you can easily determine if the phase-locked loop is running normally. If, for example, you can switch channels without changing the voltage at C115, then the vco frequency hasn't moved as it should and something is wrong. If the voltage seems to hop around in great leaps as you rotate the channel selector, then the channel switch is probably wired up to the PLL incorrectly.

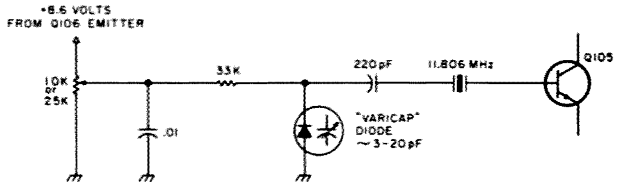

Fig. 7. Fine tuning with a varicap diode.

Another good means of testing for proper operation is to listen to the output of the loop mixer with a receiver. Remember that on channel 1 the loop divider is set to 320 and that on channel 40 it is set to 364. That means that the output of the mixer buffer, Q103, will be at 3.200 MHz on channel 1 and 3.640 MHz on channel 40. Accordingly, when the channel is set to 36, the output of Q103 should be on 3.600 MHz, and that can be easily verified by connecting one end of a length of wire to the antenna terminal of an 80-meter receiver and wrapping the other end (insulated, with no direct electrical connection) around Q103. You can figure out which channel position corresponds to 36 by counting backwards from channel 40; that channel you can find by watching for the large voltage change across C115 as the loop jumps from channel 40 to channel 1.

As an aside, it's interesting to note that the rig can now be used as a crystal-controlled calibrator which can be walked in precise 10-kHz steps across the bottom portion of 80 meters. The 3.600-MHz output on channel 36 can be zero beat with your crystal calibrator by adjusting the 10.240-MHz oscillator; then the PLL signals will be just as accurate on any of its channels as your calibrator is at 3.6 MHz.

With the PLL modifications complete and operating, the set should operate as an AM rig (into a dummy only!) from 27.925 to 28.365 MHz. By peaking up the receiver front end (T104 and T105) and connecting an antenna, you should be able to hear some CW signals, though without a bfo you won't be able to copy them. The transmitter can be peaked into a dummy load by adjusting L103, L102, T102, T103, L106, L109, and L110. You'll find that the first three adjustments mentioned are the sharpest tuning ones. I would suggest peaking everything up on 28.115 MHz (channel 16) since most of your operation will be within 100 kHz of that frequency.

The remaining steps in the basic CW conversion are the bfo addition, the AM to CW transmitter change, and the provision for fine tuning. These steps were covered in detail in the first article so will only be mentioned briefly here. The bfo is actually the 10.695-MHz transmit carrier oscillator, Q109, which can be turned on during receive by connecting the supply end of the 3.3k emitter resistor (R119) so that it gets 8.5 volts all the time in-

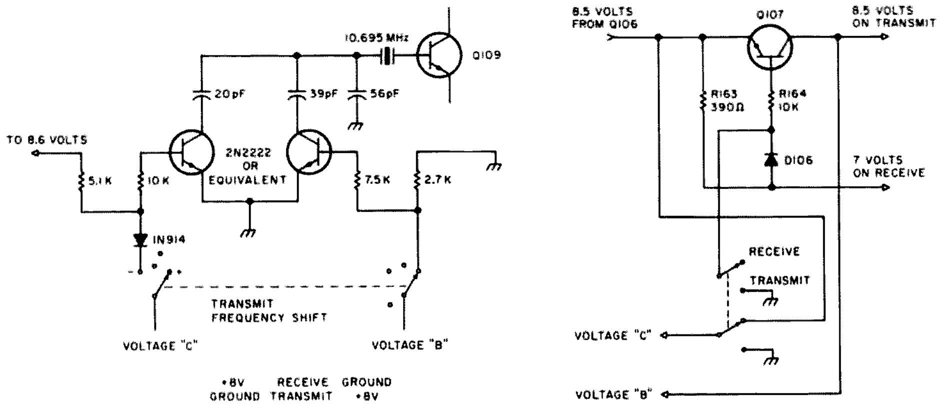

Fig. 8. (a) Circuit to provide a selectable frequency offset during transmit. (b) Circuit for manual T/R switching.

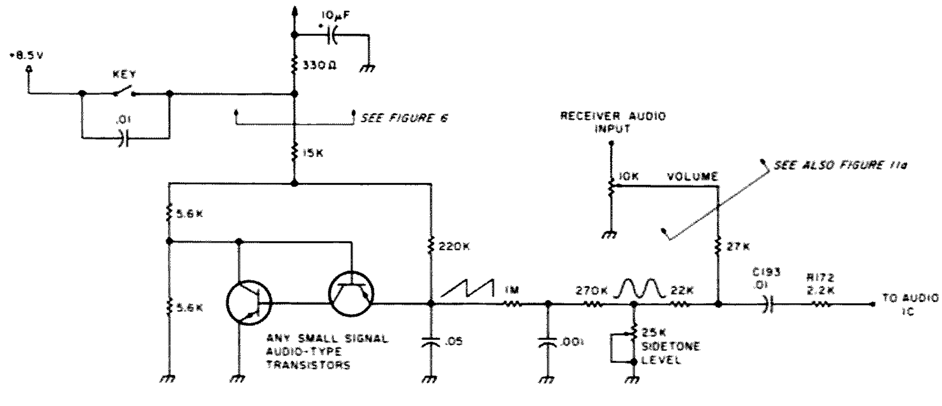

Fig. 9. Sidetone oscillator circuit.

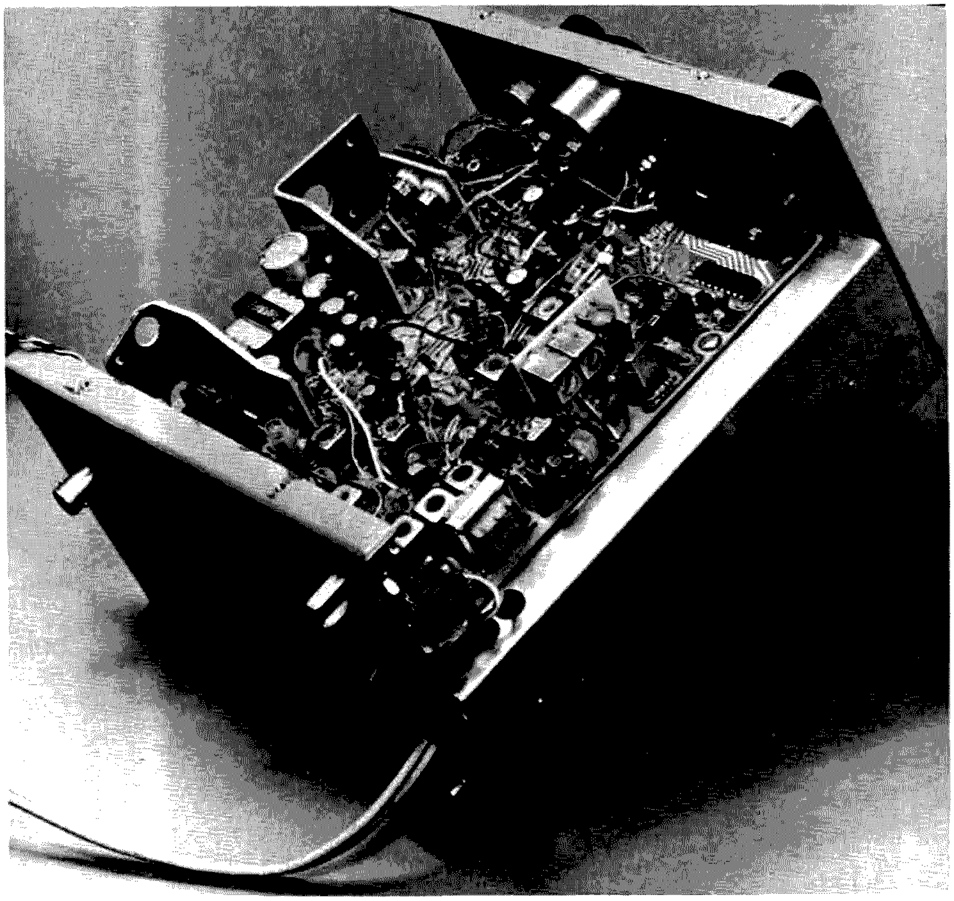
stead of only when the rig is transmitting. The emitter of Q106 (the 8.5-volt voltage regulator) is a convenient source for this voltage. The circuit change is shown in Fig. 4.

Putting the transmitter on CW is almost as simple. First the modulator output is disconnected from the transmitter driver and final amplifier by the removal of diode D105 (located just behind the audio transformer). The transmitter stages are then powered by wiring the 12-volt line directly to what used to be the cathode end of the diode. The final and driver are class C amplifiers so they won't draw any current until driven and there is no need to switch this power line. It is prudent to keep a load on the audio power stage at all times, but at this point there is no load during transmit because the modulator function is disconnected. The microphone push-to-talk switch normally opens the speaker circuit during transmit and that should be rewired so that the lower end of the speaker is connected to ground at all times. The output transformer is also rewired so that the speaker circuit does not operate with a 12-volt bias. This step helps reduce speaker thumps caused by the 12-volt supply dropping when the transmitter is keyed. These modifications to the transmitter are shown in Fig. 5.

Finally, some provision must be made for keying the transmitter, and that is done by keying the B+ line feeding the transmit mixer as shown in Fig. 6. The RC filter added in series with the power lead softens the rise and fall times enough to give brisk but clickless keying.

The fine-tuning modification is shown in Fig. 7. The 11.806-MHz heterodyne oscillator is tuned over about a 4-kHz range with a varicap diode, thus giving after frequency multiplication a 12-kHz shift in operating frequency. If your junk box doesn't have any varicap diodes, you could substitute a 35-to-55-pF trimmer capacitor, but the diode is a neater method. Not all tuning diodes are the same and you may have to try several or put several in parallel in order to get the required frequency change. Notice that as the oscillator is moved around in frequency, the phase-locked loop will force the vco to move in step so that the output signal of the loop mixer (Q103) will not change in frequency.

At this stage of development the rig is ready to go on the air. Keep in mind that the zero-beat frequency is the transmit frequency and people will have a tendency to move in that direction. Once you realize that is happening, you can ask the other fellow to stay a kHz offset from your transmitting frequency, or you can simply move the fine-tuning knob a bit when you start to receive. That's a nuisance, but not really a big problem when you get used to it.

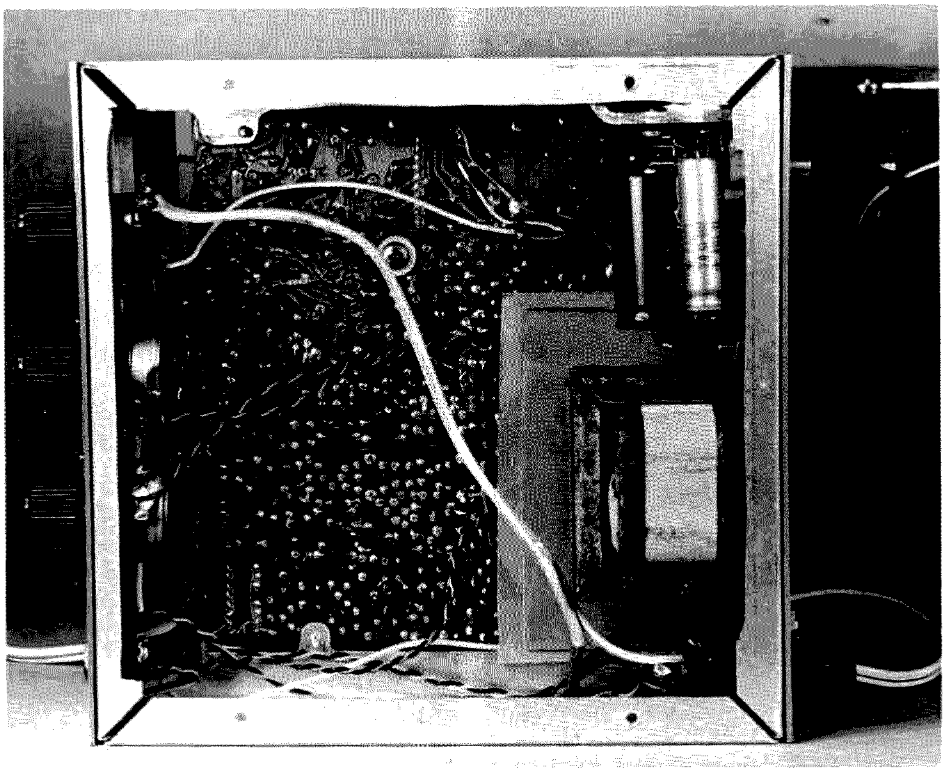


Back inside view. Note rear panel BNC for rf, miniature jack for external speaker DPST switch and male jack for external dc supply, and ac fuse for internal supply.

Stage Two—Some Convenience Features

There are a lot of features which can be added to the basic transceiver to increase operating convenience. The most appreciated will probably be a means of automatically offsetting the transmitter's frequency from the receiver's and the sidetone oscillator. The receiver performance can be increased considerably by removing the agc circuitry, which is now responding to the bfo instead of the other station anyway, and controlling the rf and i-f gains from a front-panel potentiometer. There are some changes which can be made to increase the sensitivity of the detector—mainly the removal of the noise limiter. Last but not least is the addition of an active audio filter to give the receiver some much needed selectivity.

The way to offset the carrier oscillator is shown in Fig. 8. If you examine the printed circuit foil closely, you'll find that this same technique was destined to be used on the 10.24-MHz oscillator as a receiver offset option. Somehow it seems more natural to move the transmitted frequency without affecting the receiver. Depending on the characteristics of in-



Bottom view. Power supply module in place. Rectangular object behind the transformer is the magnetic shield described in the text. Power supply connecting wires are left long enough to allow the module to be moved for circuit board servicing. Note that the cut-out portion of the chassis top allows for dc isolation of the PC board ground.

dividual crystals, there may be some changes required in the sizes of the 56, 39, and 20-pF capacitors. Those values with my crystal gave a ±700-Hz offset. The circuit shown is designed to be mated with voltages available from the break-in sequencing circuits described later. If you are going to use a mechanical switch for the transmit-receive changeover, then the circuit of Fig. 8(b) is an easy means of getting the two controlling voltages.

The circuit for the sidetone oscillator is shown in Fig. 9. There is nothing special about this circuit, but it does use few parts and draws only about .3 mA of current. The tone can be adjusted by changing the size of the 220k resistor if desired. The oscillator generates a sawtooth which is a bit harsh-sounding, so a low-pass filter comprised of a 1 meg resistor, the .001-uF capacitor, and the 270k resistor is used to smooth out the waveform. There is nothing critical about any of these components or the transistors used and value changes of as much as 30% will probably go unnoticed.

Several changes were made to the detector circuitry to make it more suitable for CW use. The "before" and "after" schematics are shown in Fig. 10. Two changes are clearly needed: The S-meter and agc are removed because they now respond to the bfo signal instead of incoming Morse signals. This was particularly troublesome since the agc insisted on keeping the receiver gain low, and so the first change is to control the agc line with a front-panel 25k pot. (I had hoped that this control wouldn't be necessary and that the receiver could be set for maximum gain, but it turns out that strong signals on nearby frequencies, i.e., local CBers and worse, can cross-modulate the front end and show up in the audio output. This is probably due to using the 10.695-MHz bfo as much as poor front-end design. In the future, I want to try adding a proper 455-kHz bfo, but for now I can significantly reduce the problem by using the i-f gain control and switching when necessary to a horizontal dipole. Most CB operation is with vertical antennas, so the local operators are attenuated by 3 or 4 S-units when a horizontal antenna is used.)

Also removed from the detector circuit is the noise

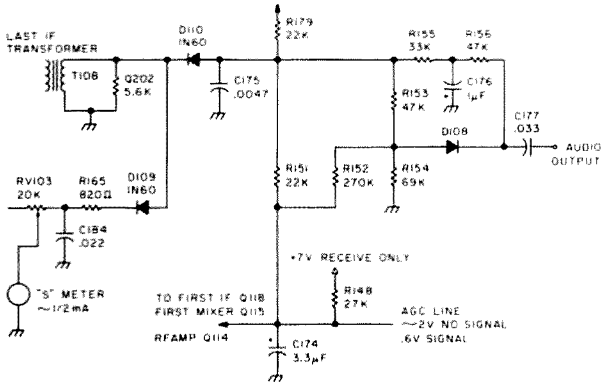


Fig. 10(a). Detector circuit before modification.

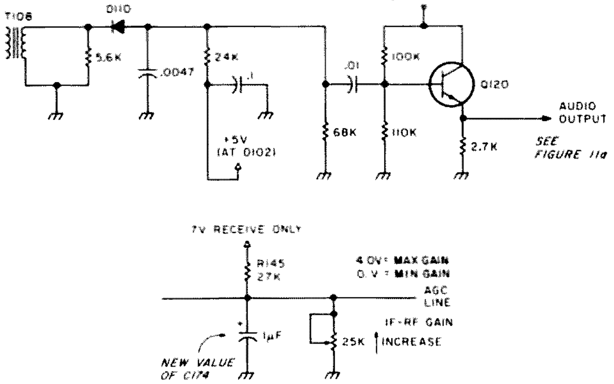

Fig. 10(b). Detector circuit after modification.

limiter consisting of R155, R156, C176, and D108. These components are in a rather clever arrangement which clips both low-level fuzz and high-level spikes. Interestingly, the circuit on the board is always wired up and operating and it was only the models which had the provision for turning the circuit off (by putting a switch in place of the jumper J106) that advertised the feature!

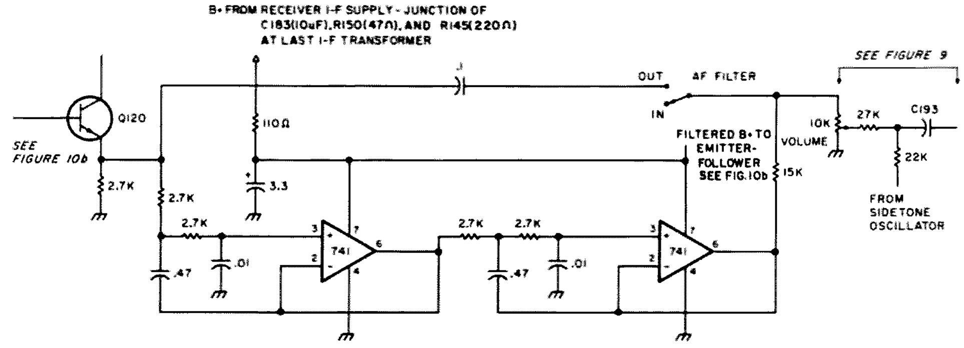

Fig. 11(a). Circuit diagram for active filter.

The squelch is also removed, but the squelch transistor, Q120, is rewired as an emitter-follower buffering the audio output signal. There are two reasons for this addition. It was found in the breadboard stage that the original volume control setup, a 50k pot from C177 to ground, was susceptible to picking up hum as I probed around the circuit board with a finger. The use of an emitter-follower makes it possible to have all of the wires leaving the board be low-impedance lines, while at the same time the high-impedance portions of the circuit are kept physically small, which means that hum is much less of a problem. The emitter-follower is also a good interface between the detector and the active audio filter. As can be seen in Figs. 11(a) and 10(b), the same B+ decoupling circuit is used to power the active filter and emitter-follower. There is a lot of audio gain after these circuits and a well-filtered voltage source is a must to prevent audio oscillations.

The audio filter design is straight from *Solid State Design for the Radio Amateur* (an ARRL publication). A peaked low-pass characteristic was chosen because of its high attenuation above the cutoff frequency. Two sections are used, each with a Q near 5 and a cutoff frequency of about 800 Hz; the overall frequency response is shown in Fig. 11(b). The two op amps are operated between ground and the 12-volt supply, with the input signal being biased at 6 volts by the emitter-follower. This arrangement saves the several resistors which would otherwise be necessary to derive the bias voltage. The output of the filter is fed to the volume control through a 15k resistor, thus providing some attenuation to compensate for the peaking above unity gain which occurs at the cutoff frequency.

The 15k value was chosen so that the speaker level of an 800-Hz tone is approximately the same either with or without the filter being used. The resistor also serves the purpose of providing a high-output impedance for the filter—when the filter is switched "out," what actually happens is that the low-impedance output of the emitter-follower attenuates the filter output into insignificance. The audio from the volume control is fed into the IC audio amplifier as indicated in Figs. 9 and 11. The filter is quite a help when the band gets crowded, often making otherwise impossible contacts easy copy. With the filter switched out, it is easy to quickly scan the band using only the channel switch since even signals several kHz from bfo zero beat can then be copied.

The rf voltmeter shown in the photographs was introduced simply by inserting parts into the proper holes on the circuit board. This was another feature not wired until the last stages of manufacture. The only departure I made from the Hy-Gain layout is the replacement of the variable resistor (Rv104) on the circuit board) with a fixed 15k unit. That gives about half scale on my meter, a .5-mA unit, with five Watts of output. You can change this as necessary to fit the meter you choose. The circuit, shown in Fig. 12, has a 10-uF capacitor to filter the rectified waveshape so that the pointer won't slam back and forth with keying.

Stage Three—Full Break-in

Full break-in CW operation is something that few newer hams have experienced, principally because many amateur transceivers are designed with sideband in mind and CW added as a "tack-on." With full break-in it is possible to hear the other fellow sending whenever your key is up, even in the middle of a letter. When the stations at both ends of a QSO have break-in capability, the conversation is

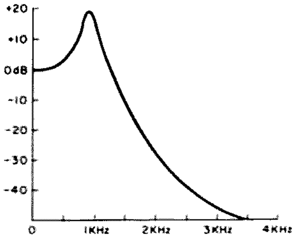

Fig. 11(b). Measured performance of filter.

very much more natural than the usual segmented contact. Break-in is also a good operating feature: It's much easier to make and continue QSOs under difficult conditions when you can hear what's going on during your transmission.

The big problem with getting a transceiver to operate full break-in successfully is the elimination of clicks and thumps in the receiver as the rig is switched rapidly between transmitting and receiving. Many things must occur in an ordered sequence as the rig is keyed. When the key is closed, the receiver must be biased off—the rf amplifier must be disabled, the agc turned down, perhaps an i-f stage muted as well. Any frequency offset in the vfo must be done before the

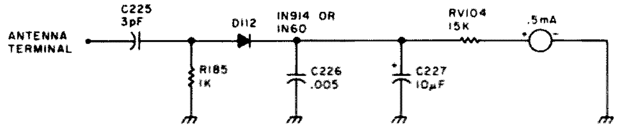

Fig. 12. Rf voltmeter added by putting parts into the appropriate positions on the PC board.

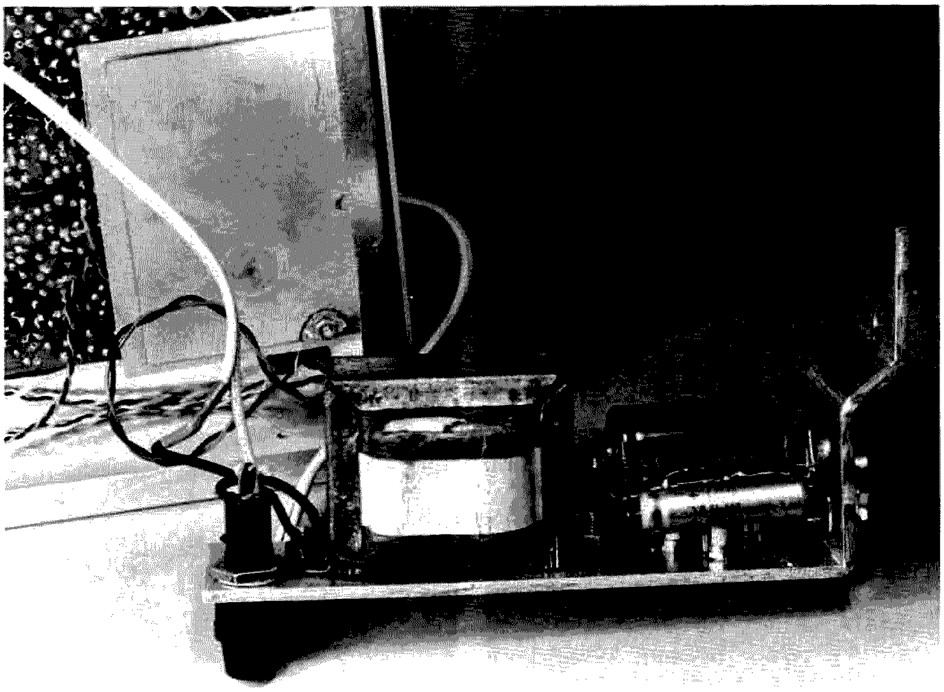

The power supply module removed from the main chassis to show construction. The aluminum bracket is 1/8" thick and transfers the power dissipated from the IC regulator into the main chassis.

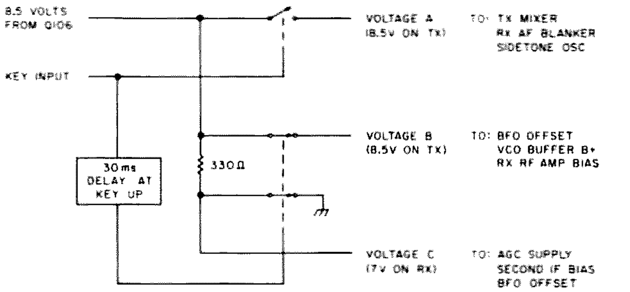

Fig. 13(a). Block diagram of break-in timing system shown in receive mode. Note that voltage C is inverse of voltage B.

transmitter comes on, and some sidetone must be inserted into the audio amplifier. The rf envelope must come up smoothly to avoid over-the-air clicks. When the key is raised, nothing should happen until the rf output has smoothly died away; then the vfo shift must be reinstituted and the receiver reactivated. Most importantly, all of these big shifts in operating condition should occur rapidly, yet without causing undue disturbances in the output audio. Ideally, the operator listening to the receiver would hear his own keying just as if it were coming from another station over the air. A very good break-in system is difficult to come by, and the circuits worked out for this application, while not providing perfect break-in, certainly provide acceptable performance.

The heart of the break-in circuitry, shown in Fig. 13, requires the addition of three transistors labeled Q1, Q2, and Q3. When the key is closed (keying current is 7 mA, which should be compatible with any keyer), Q107 is turned on directly and its output turns on the transmitter and turns off the receiver audio with a circuit which will be described shortly. The grounded keying terminal also provides a rapid discharge path for the 4.7-uF capacitor. Notice that while this capacitor can discharge through the signal diode, it must recharge more slowly through a 10k resistor. That inequality will provide a 30-ms recovery delay to keep the receiver off until the transmitter output has decayed completely away. The voltage across the 4.7-uF capacitor drives the base of Q1, and the emitter of that transistor is biased at about 2.4 volts by a forward-biased diode and an LED (which serves double duty as a front-panel power indicator). As the voltage at the base of Q1 rises and falls past 3 volts or so, the transistor turns on and off, switching in turn Q2 and Q3. The timing waveforms are shown in Fig. 13(c), with the exception of voltage B, which does pretty much the opposite of voltage C. The important fact to note is that while all three of these controlling voltages switch

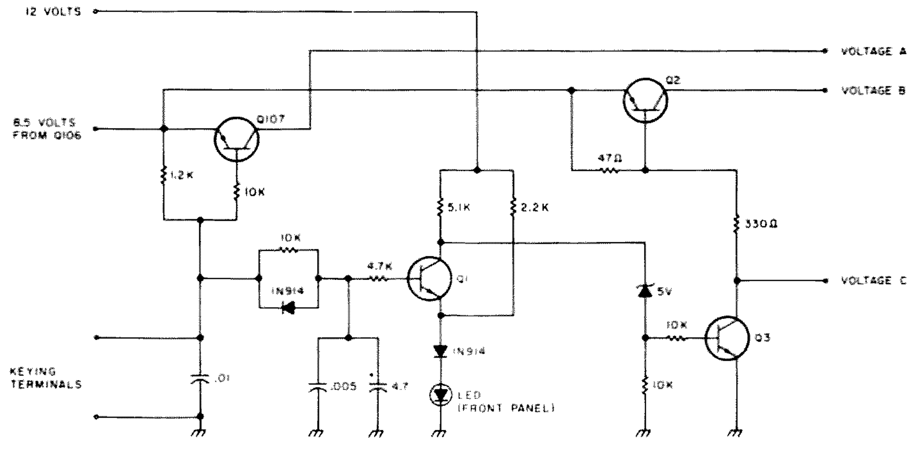

Fig. 13(b). Schematic diagram of break-in timing system. The transistors are general-purpose low power types.

simultaneously at key-down, only the collector voltage of Q107 switches immediately at key-up. As shown in Fig. 13(c), the 30-ms delay gives plenty of time for the transmitter to get off the air before the receiver is turned back on. Also indicated in Fig. 13(b) and Fig. 16 is where the three controlling voltages go in the rig as a whole.

The sequencing circuits just described give plenty of receiver protection during keying, but unfortunately they are not thumpless. Some additional quieting was achieved with the addition of the simple audio blanker shown in Fig. 14. I've used this system for several months and find its performance quite acceptable. Being a bit of a perfectionist, however, I have looked into the reasons for the remaining thumps. The complete cure would seem to require a soft exponential transition of perhaps 10-ms time constant on all of the keying waveforms controlling the receiver. The rf amplifier bias, second i-f bias, and agc line inputs are relatively easy to filter by the addition of the proper capacitors, but vco buffer B+ must be powered from a low-impedance source during transmit and so would require either the addition of another transistor or a change in the timing circuits to ensure that the receiver is off when buffer B+ is stepped up or down. Turning the receiver off exponentially may require a different sequencing circuit in any case to delay the transmitter turn-on. The system described in Fig. 13 works fine, but if you enjoy experimenting, you might look into some variations.

One last hint on reducing keying noise: Be sure to return the speaker ground wire to the circuit board as closely as possible to the ground pin of the audio IC. This will be pin 2 if the IC is a BA521 or pin 9 if it is a TA7205. Otherwise, the heavy transmitter keying current (around 1 Amp) can couple into the speaker wiring and cause a click that is not muted by the receiver gain control.

Odds and Ends—Power Supply, Cabinet, Future Work

All in all, this makes a very nice little CW rig. The only reason it might be classified as a toy is that it is so inexpensive to get on the air. If your junk box contained several old transistor radios, the total cash outlay for the project to this point should be something less than $20. I built the rig to this level and used it for about a month before deciding on a cabinet. The construction for the final enclosure is pretty well explained by the photographs. The board was mounted into the top surface of a 7″ × 7″ × 2″ chassis, front, back, and bottom plates were added, and a U-shaped cover was fabricated to form the top and sides. A 2½″ × 4″ oval speaker rescued from a junk TV set was mounted behind a grid of holes drilled in the top of the U. The holes were drilled using a piece of scrap perfboard as a guide—that made it easy to get such a nice even array. A piece of thin black cloth contact-cemented over the holes from the rear (after painting the box) protects the speaker from dust and dirt. The U-shaped piece happens to be a section cut from a large steel chassis bottom plate so I was able to solder nuts to the underside as anchors for the speaker mounting clamps.

It is certainly a convenience to have a built-in ac-operated power supply, and with any number of excellent IC regulators available for a couple of dollars, it seemed a shame to tie up a bench supply. The power supply shown in the photographs was built around a transformer and regulator found in my junk box. The circuit suggested in Fig. 15 will fit in the same space and shouldn't cost more than $15 if you buy all new parts.

As can be seen in the photographs, the power supply is built as a separate module. The aluminium bracket is fashioned from part of an old 1/8″ thick rack panel and fits up against the insides of the main chassis which then serves as a heat sink. To provide for portable opera-

tion with an external 12-volt battery, a DPDT switch and male jack are mounted on the rear of the set to select the desired power source. Note in Fig. 16 that the power switch on the back of the volume control is also a DPDT unit and that this allows switching of both the ac and dc power lines so that the switch will work with either internal or external supplies.

What is not clear in the photographs or schematics is that the entire enclosure is isolated by capacitors from the circuit board's dc ground. This feature could prevent some fireworks if you used the rig in a car with a positive ground electrical system! The dc isolation is provided for on the board by separate foil mounting pads, but you have to be careful to use isolating washers when mounting the key and headphone jacks.

While on the subject of power supplies, a word or two about dc supply voltage is in order. The transmitter rf output will vary from set to set because of transistor differences, but it will always go up with increased supply voltage. With my transmitter, 11 volts gives 3 Watts, 12 volts gives 4 Watts, 14 volts gives 5 Watts, and 15 volts gives 5.5 Watts of transmitter output. My power supply is set to deliver 12.7 volts on receive and this falls to 12 volts on transmit because of the 1.5-Amp current drain. Going to a 15-volt supply would provide an extra Watt and a half of output, but that is only 1.4 dB or less than ¼ of an S-unit worth of signal gain. You will notice in the photographs that the output transistor's heat sink is not attached to the cabinet wall as intended for the CB application. With a 12-volt supply, the final stage input is about 11 Watts, and with 4 Watts of output power, that leaves 7 Watts of heat to be dissipated by the heat sink. After a long transmission, the heat sink gets warm to the touch though not uncomfortably so. Higher input power would probably require that some attention be paid to this heat sink as well as the power supply. All in all, it doesn't seem worth the trouble for less than ¼ of an S-unit.

Whenever a power transformer is mounted in close proximity to sensitive circuits, the possibility exists of magnetically coupling 60-Hz hum into the signal path. For this reason, the transformer was mounted as far as possible from the audio section of the printed circuit board. Despite this precaution, there was a noticeable amount of hum modulating the received signals whenever the internal supply was used. This problem was completely cured by shielding the circuit board from the transformer with a 2½" × 3½" plate of sheet steel. As can be seen in the under-chassis photograph, this shield is mounted directly between the power transformer and the circuit board with a slightly larger rectangle of thin cardboard between the shield and circuitry to prevent shorting the PC runs together. The longer wire ends protruding below the PC card were also trimmed with a pair of side cutters to keep them from wearing their way through the cardboard. The shield is held in place by a nut soldered to one corner which is engaged by one of the screws holding the circuit board to the chassis.

The conversion steps described in this article are mostly simple circuit changes, but they often require the addition of several parts to the modified circuit. If you haven't worked much with printed circuit boards, you may wonder how additional parts can be added to an existing foil pattern. Actually, there are several ways to accomplish that feat.

First, there are lots of unused foil islands on this board. Most of these were supposed to be used in the addition of optional features and so are available to use when making circuit additions.

Next, there is a lot that can be done to add parts by modifying existing foil runs. Often in changing a circuit a long foil run is freed up when the component or circuit at one end is no longer needed. A sharp knife can be used to cut and remove a short section to open the circuit, and then the remainder of the run can be sectioned into several other islands. To make connection to these islands, a small hole can be drilled next to the foil (runs are so narrow that drilling a hole through them can ruin them) and the paint scraped off the copper to permit soldering.

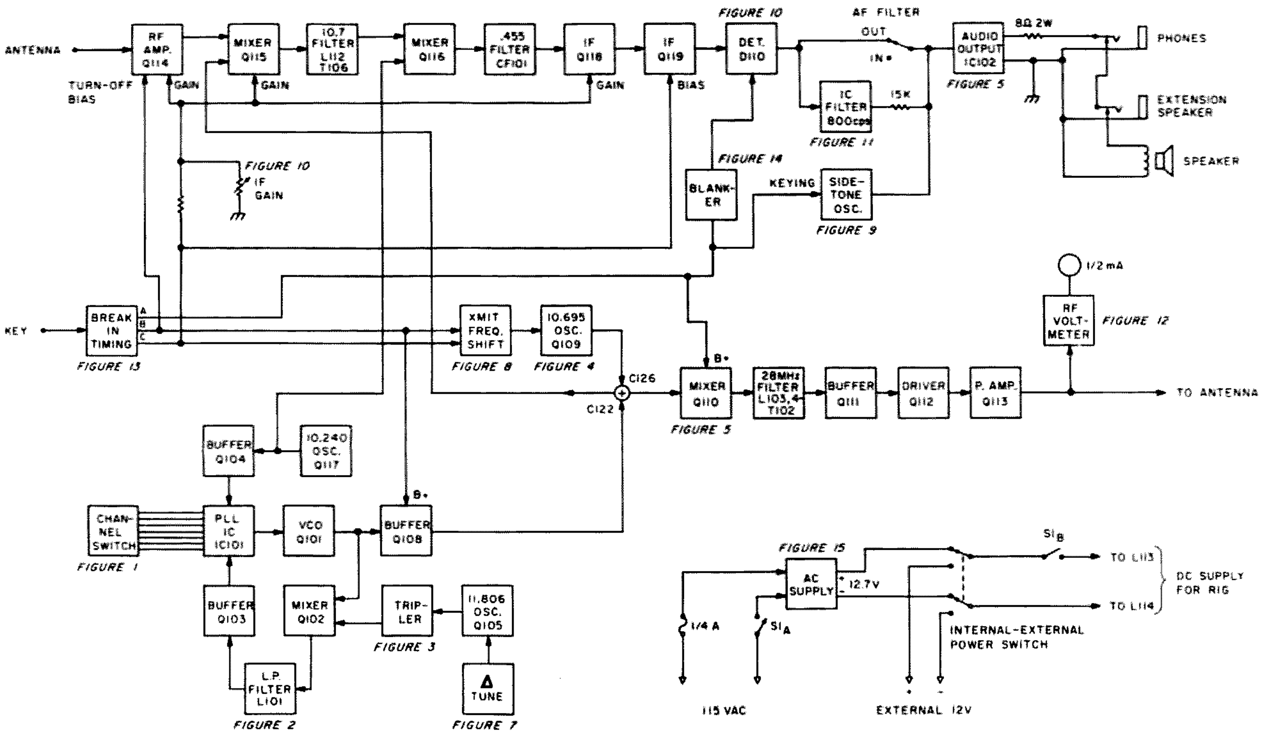

Fig. 16. Block diagram of the converted transceiver.

Be sure to leave the section of copper long enough that the whole strip won't come unglued when you solder to it. Remember that for modification purposes the primary need is for component support since the actual circuit connections can be made with small insulated jumpers. To provide adequate support, it is not necessary that each of a component's leads be anchored to the foil. It is quite acceptable, for example, to have a small resistor standing upright with only one end actually soldered to the board and the top end connected elsewhere with a jumper.

It is also possible to make connections by soldering new leads to other wires where they come out on the top of the circuit board, though this technique is less desirable because it can mean that to disconnect one component may require unsoldering several.

The principal thing to remember when you're looking for a way to add a component is that you're modifying the board, not manufacturing it. Amateurs often unconsciously accept the manufacturer's techniques as ideal standards when actually the manufacturer laid out the board the way it is only so that it could be built efficiently and reliably by the people and machines on his production line. The techniques suggested here, while certainly not as efficient in construction time, can be just as reliable as the manufacturer's if they are applied neatly and carefully. Take the time to make good neat solder joints. If a part seems loose on top of the board or a component wire has to support a heavy mass, use a dab of epoxy to help carry the load. A lot of the problems I had with these boards were due to something like a support wire on one of the output coils coming loose on the underside of the board and causing intermittent open circuits. A little care in construction can make a big difference in reliability.

This project got started because the basic circuit board was so cheap that I just had to find a use for it. The guiding philosophy has been to keep the cost down by avoiding expensive or exotic parts. There are no crystals to be ordered and no strange ICs you have to mail away for; if your junk box doesn't have what you need, the local parts store probably does. This design approach has produced a rig whose performance is better than I had expected, but there are still improvements to be made by the experimenter. The thing which has the biggest payoff potential is an improved bfo. The 10.695-MHz technique works, but the bfo signal passes through all of the i-f stages of the receiver and that puts a limit on the i-f gain usable (before the receiver chokes on its own bfo) and probably generates some spurious responses as well. A bfo at 455 kHz has several advantages aside from the i-f considerations: The detector stage could be replaced with one of the simpler product detectors for better linearity, a separate agc detector could be included and the agc put back into service, and (though much less important) the S-meter could be hooked back up. There are two ways to go about adding the bfo—with and without a crystal. If you have or can get a 455-kHz crystal, you're all set; otherwise, you might try making a free-running oscillator with an old i-f transformer. The free-running version may work fine—after all, the frequency is low and drift certainly isn't the problem it used to be in the vacuum tube days.

In closing I would like to express my appreciation for the photography and help with the text tendered by Steve W1GSL. In a project of this size, it is easy to get lost in small details, so an impartial but informed observer is an invaluable aid.■

Hands Across the Water

—CW lives on historic Cape Cod

The operator casually twirls the passband control of a $7,000 Watkins-Johnson receiver as he peels another CW signal off the side of a noisy pileup. He's been at it—slapping out 20-word-per-minute CW—for almost eight hours now. Soon his shift will be over and someone else will take his place.

As he concludes another contact, he habitually spins the antenna switch, sampling the various rhombics he uses for receiving while trying to pull yet another signal up out of the pack that has zero-beat on top of him. Europe, the Med, the Persian Gulf, Africa, the South Atlantic—as the rhombics click by, one signal finally surfaces above the rest.

Tapping his bug in response, the operator keys his remote transmitter. From the shore of a sleepy tidal marsh green with sea grass five miles away, his antennas—mostly doublets, dipoles, and curtains—march out toward the rolling Atlantic. Two 4-500s drive two 4-5000s and his signal is easily heard on the other side of the world.

After a brief exchange of formalities, the text of a message is passed between another ship at sea and the largest and oldest commercial CW station still operating in the United States: RCA Globecom's WCC. In a few minutes the shift will end, the paddle will be passed, and another watch in the life of a professional CW operator will come to an end on Cape Cod.

Fig. 1. List of hams working at WCC.

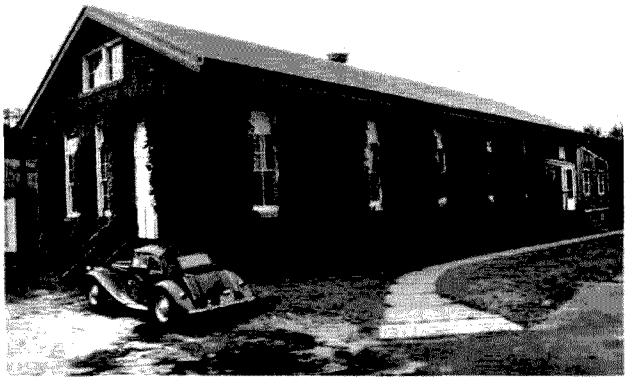

Fig. 2. In this rustic, ivy-covered building with a history as long as radio communication itself, 900 messages a day are handled by 21 professional CW operators, almost half of whom are hams.

Back In Time

Visiting WCC, RCA's marine message-handling station in the town of Chatham, Massachusetts, a good ways out on Cape Cod, is like taking a trip back through time. Once there, you're back in the Golden Age of shortwave radio communications. The rustic ivy-covered brick buildings, erected by the Marconi Company in 1914 (only eleven years after the first transoceanic radio

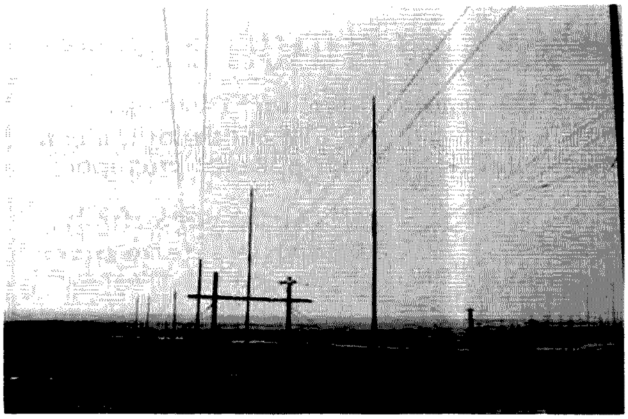

Fig. 3. At a remote transmitter site on the edge of a tidal marsh, WCC's antennas march out toward the Atlantic Ocean. These doublets and dipoles are fed with 10 kW of rf on 6, 8, 12, 16, and 22 megahertz.

message was sent from nearby South Wellfleet), are still intact. Most stand vacant now, victims of a technology to which they helped give birth. One, however, is as busy as ever.

Though methods of long-range radio communications have changed drastically during the last 60 years, the nobility of WCC remains. This station, which once provided weather information for Charles Lindbergh, maintained contact with Richard Byrd on his ill-fated trek to the pole, and monitored, then lost, Amelia Earhart's distant transmissions, has survived. And, in spite of the pressures for modernization, development, and progress surrounding them, these buildings, like the CW they shelter, are holding their ground in 1982.

What impresses most on a visit to WCC is the fact that in this high-speed, packet radio, orbiting-satellite world we live in, there is still a place where the Morse code is hammered out twenty-four hours a day, for a profit.

Edgar Hammons, manager of WCC: "Well, though we've seen a gradual decline over the last four years in the number of CW messages we handle, we're still quite busy." Though it may be on the decline, the WCC CW traffic list is, nonetheless, impressive. During the course of one twenty-four-hour operating day, 900 messages will be handled by WCC—most of them on CW. In rotating shifts, the station's 21 CW operators provide thousands of ships at sea with a reliable and inexpensive means of contacting their home offices.

"Satellites and digital communications are fine," says Hammons, but, he adds, "they are also extremely expensive to install and maintain." A modern shipboard satellite terminal can cost a ship owner over $50,000. As a result, many owners cling to CW and WCC as their only reliable communications link.

In addition to conventional CW, WCC offers customers with the proper equipment SITOR communications services. SITOR (Simplex Telex Over Radio) operates as an answer-back RTTY system. Running at 75 baud (50 wpm), SITOR transmitters and receivers at WCC echo message characters back to the ships that transmitted them. The result is error-free automated copy. In some instances, SITOR-equipped ships and their home offices can be connected directly through WCC for more private (and

Fig. 4. A new sign welcomes visiting amateurs to RCA's oldest commercial radio facility.

expedient) communications. A three-minute SITOR exchange with WCC costs an American ship about $9, a substantial savings over the CW rate which is based on a 52¢-per-word charge.

For the time being, however, CW is still the mainstay of WCC operations. After the hourly traffic list is broadcast by the station on the 4-, 8-, 12-, 16-, and 22-megahertz marine bands, CW signals pile up for each of the eight operators manning the shift. Once he establishes contact with a ship, a WCC operator types the text of the message he has received or sends the text of the message he is holding. Received messages at WCC are passed to one of three printer clerks via a small conveyor belt. The printer clerks then key the typewritten messages into a teleprinter that connects directly to an RCA message-center computer in New Jersey. At this point, the computer takes over and automatically telexes the message to its final destination.

The obvious thing about WCC's message-handling procedures is that they are highly labor intensive: It takes a lot of people to get a message delivered. According to manager Hammons, however, staffing the station poses little problem, despite its location on remote Cape Cod. "We have no openings here at present," says Hammons, "although we frequently do. In fact," he adds, "I have two applications for CW operator in my desk drawer right now. Tell your readers that I'm always glad to get new applications, though."

WCC's operating staff numbers 34; 21 are CW operators, nine are marine telex clerks, and four are technicians. There are 13 hams on the staff (See Fig. 1), almost 40% of the total employees! The starting salary for a CW operator is approximately $23,000 per year and the present contract calls for 10% yearly increases in wages.

Where does WCC find professional CW aficionados to man its station? Basically, there are two sources. Station operators come from the ranks of the military or from the ranks of amateur radio. Of the 21 full-time CW operators at WCC, eight are hams. In addition, all four technicians who attend to the day-to-day equipment maintenance and repair are hams.

Standard equipment for

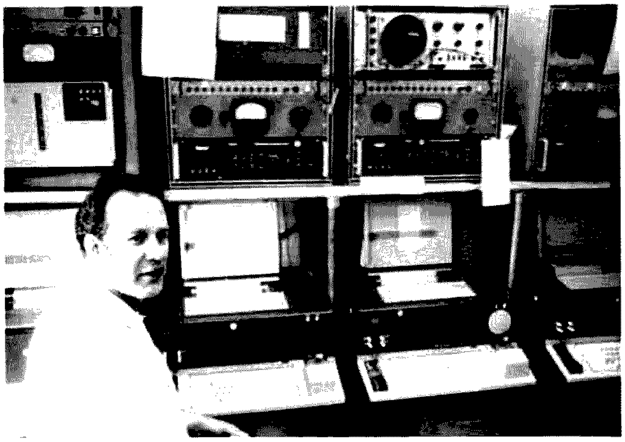

Fig. 5. K1TV manning the SITOR transmitter.

Fig. 6. A typical WCC operating position. Emphasis is put on receiver performance and typing ability.

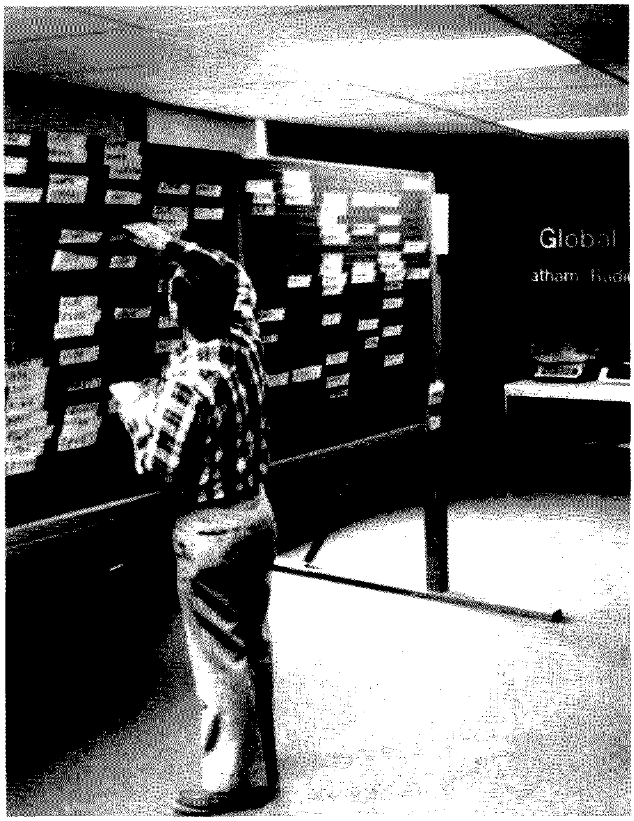

Fig. 7. Outgoing traffic is posted on the WCC message board. Between 700 and 1000 pieces of traffic are handled on a typical day.

hams operating at WCC includes a second class commercial telegraph license and a well-worn Vibroplex bug. Hand keys are available at each operating position, but, in a partial concession to modernity, most operators prefer to use their own mechanical keyer. No electronic keyers are in evidence, although one ham on the staff has been experimenting with the use of a CW keyboard.

Traffic at WCC is usually passed at around 15 words per minute but, in some cases, more slowly if the shipboard operator is not up to speed with the WCC crew. The quality of the code coming into WCC, both in tone and in style, varies. Some shipboard signals chirp like late-night Russian DX on 40 meters, and some of the fists sending these signals are straight out of the Novice bands.

Through it all, however, the cool professionalism of the WCC crew prevails. It is only rarely that the text of a message must be repeated by a tired operator in a distant port of call.

The Future at WCC

The future of WCC as a CW operation is open to question. Ed Hammons, conceding that CW is being eclipsed by the more cost-effective SITOR system, thinks CW will be around for some time, however. "I believe that we will always have Morse code," he said, adding that, "eventually it may not be the biggest segment of our business." Hammons went on to say that SITOR is gaining in popularity rapidly and that, at present, WCC is handling a new ship on SITOR almost every day.

For the CW operators at WCC, all of whom take turns babysitting the SITOR equipment now and then, CW remains more than a business; for most, it is a passion. One of them who argued most adamantly for the maintenance of high-quality standards on CW, as well as for the retention of CW as a requirement for amateur licensing, was not even a ham. He simply felt that CW was "something special, something human" in our digitally-automated world of tomorrow.

Sentimentality aside, the fact remains that a substantial portion of the message traffic that passes between the U.S. merchant fleet and their home offices in this information age in which we live does so via CW. For beleagured CW stalwarts who constantly find themselves on the defensive when confronted by their SSB- or ASCII-loving ham brethren, that may be comforting to remember.

It may also be reassuring to remember that, should the cares of this modern information age become too great, there is an alternative. In a quiet village on old Cape Cod there is an ivy-covered building with a history as long as radio communications itself where a CW-loving ham can earn a decent living by pounding out ten kilowatts of Morse for all the ships at sea. All he needs is a love of CW and a well-broken-in, vintage Vibroplex bug.

Amateurs visiting Cape Cod are welcome to tour WCC. The station management requests that all visits be made between 8 am and 4 pm, weekdays only, and, when possible, arranged one day in advance. ■

A Three-Piece CPO

—battery not included

Recently, I had need of a code-practice oscillator to teach a Girl Scout troop how to properly send the international distress signals. We had already learned the emergency signals for ground-to-air, railroads, and the trucking industry. (How would *you* signal an oncoming train that a bridge was washed out?) It was just as important that the girls knew how to signal for help using Morse code. Hence, our program on emergency communications.

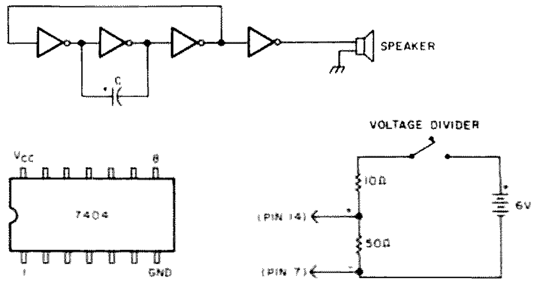

Fig. 1. The simplest cpo. The IC is a 7404 low-power Schottky hex inverter. C is a 5- to 30-μF electrolytic selected for desired pitch. The speaker is a 2-inch, 8-Ohm unit.

The cpo itself was built using 1 IC, 1 capacitor, and 1 speaker! The volume was sufficient for our meeting area and four C-cells wired in series provided the required 6 volts. Did I say 6 volts? Oh, yes, not wishing to build a 5-volt power supply (as required by the Schottky IC) for the circuit, I just used a voltage-divider network consisting of two resistors wired in series with the battery pack. One resistor was 10 Ohms, the other was 50 Ohms. The 50-Ohm resistor will function just like a miniature 5-volt battery. One end of the resistor will be the positive terminal and the other end will be the negative terminal. The current drain of the IC is so small that there is no problem with this arrangement.

The circuit was soldered directly to an IC socket and the speaker. I could have soldered directly to the IC pins, but happened to have a spare 14-pin socket in my junk box.

I used two 100-Ohm resistors in parallel to produce 50 Ohms. A standard 51-Ohm resistor would have worked just as well, as the maximum voltage for the IC is 5.25 volts.

The schematic diagram is self-explanatory. Build it and enjoy! ■

Coherent CW for VHF

—will it work?

The so-called system of "coherent CW," which is actually a form of matched filtering with extremely narrow bandwidths, has been applied to the high-frequency spectrum and should have interesting VHF applications. Information is typically communicated at a bandwidth of only 10 Hz, resulting in a remarkably high signal-to-noise ratio. Successful contacts have been carried on at low power levels (such as 1 Watt) on 80 meters and over long distances (California to Asia) on 20 meters.

Interesting technical byproducts have been the development and use of the Petit filter with readily adjustable narrow bandwidths, the production and use of high-quality frequency synthesizers, and major advances in frequency stability, along with greatly improved methods of frequency measurement. Another important factor is the use of keyers with precision timing and phasing for each bit of each Morse element, using either the Accu-Keyer or special computer keying programs.

To our knowledge, the application of all of these technologies has not been made to VHF communication, but some of them may hold promise for important future advances at these higher frequencies.

Why Narrow Bandwidth at VHF?

The use of FM and the promise of packet communication of digital information at high speeds has drawn attention to the advantages of the wider bandwidths available at VHF. But for some applications, a completely opposite approach may be better. Suppose that we would prefer to get maximum range or highest intelligibility for only a brief message or one that might just as well go slowly. This could be, for instance, where the most important information might be evidence of contact through call letters and a signal report.

Let us make a simplifying assumption (not exactly true) that the methods of modulation and detection would be the same for either wide- or narrow-bandwidth communication and that the bandwidth required is the same as the bits sent per second. Curiously, 10 kHz completely filled for one second with 10,000 bits of information (as in a packet) would transmit exactly the same number of bits as 1,000 separate channels, each 10 Hz wide and each transmitting only 10 bits during the second (as in CCW). Noise power on each channel is proportionate to channel bandwidth. So, for the same signal-to-noise ratio, each narrowband signal using one milliwatt would do as well as the packet transmitter using 1 Watt. All the narrowband stations together would use

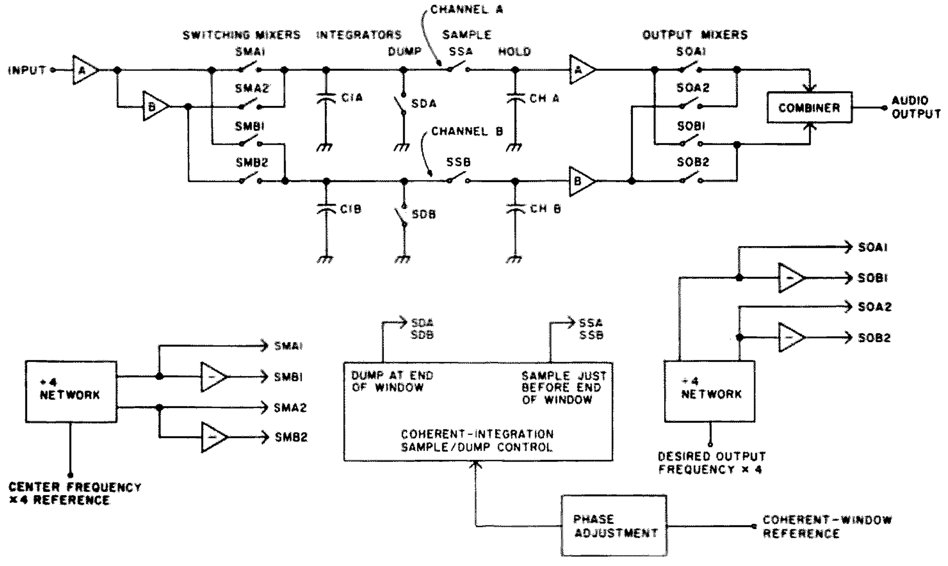

Fig. 1. Block diagram of the Petit filter (originally appeared in QST, May, 1981).

1 Watt—or if we preferred to use only one channel, we would use the same total amount of energy by taking 1,000 seconds to send the same message!

Thus, neither method has an inherent advantage in bits of information per unit of transmitted energy. So our choice will be made by whether we prefer speed at higher power or slowness at lower power (or perhaps greater range at the same power, at the sacrifice of speed).

We should note that if the total time is minimally used by packets or if the total frequencies are minimally used by lower-power narrowband signals, the chances of interference to either mode by the other mode in the same frequency range are very slight. Each tends to be immune to the other. (This will not apply, of course, if some greedy DXer tries a kilowatt on CCW!)

The Narrowband Matched Filter

We usually think of Morse code in terms of dot and dash patterns, each attached to a particular letter, number, etc. But Morse can be just as well conceived as a digital system based on an "on" (= one) or "off" (= zero) condition during a series of equal time intervals. Each time interval would be the length of a dot. A dot is a single one. A dash becomes three consecutive ones. A space within a character is usually one zero, between characters is three consecutive zeroes, and between words is seven consecutive zeroes.

If the timing of the Morse transmitter is precisely controlled, it will be sending a serial stream of digital information in classical binary form. Then a receiver can be constructed with a filter and detector carefully matched to decipher the digital message.

Despite the title of "coherent" CW, there is no way to preserve the phase coherence between the transmitted and received waves. Ionospheric or tropospheric media always cause some phase disturbances. The true essence of CCW is in the use of a matched filter.

At code speeds used by amateurs, bandwidths of matched filters can be extremely small. Typical dot lengths are a tenth of a second, producing about 12-wpm code speed. A Petit filter matched to such a signal has a 3-dB bandwidth of only 9 Hz. This allows for an outstandingly good signal-to-noise ratio.

The Petit Filter

The Petit filter refers to a design by Ray Petit W7GHM. Although the details of its circuit are described in the bibliography at the end of this article and will not be repeated here, a block diagram is shown in Fig. 1. The filter has several distinct features:

1. It operates near zero beat. Usually the filter bfo is at 1 kHz and it tunes to a receiver signal output very close to 1 kHz.

2. Two filter channels are used with a 90-degree phase difference between them. This quadrature phasing is necessary because near zero beat there is always the possibility that output in one channel alone might be in such a phase as to give almost no output. In that case, the quadrature channel output would be nearly maximum. Adding the two channels ensures an output whenever a signal is really present. The phase shift between the two 1-kHz-filter bfo signals is obtained by properly dividing 4 kHz by 4.

3. Matching is achieved by using a high-precision secondary frequency standard to control all functions on both transmitter and receiver. This not only ensures close tolerance in receiver tuning (within 1 Hz), but also close synchronization between received digital pulses and filter pulse sampling. A controlled-pulse repetition rate is not sufficient to hold this synchronization; the phasing of the time sampled by the filter must also be adjusted so that the transmitted signal is framed within a "window" opened to each signal pulse. Ten phasing-switch positions allow adjustment of the framing in 10-ms steps. Initial adjustment is made by listening for the clearest reception of a series of transmitted dots.

4. Each 100-ms window opening is the result of an integrating circuit in each filter channel. The integrated output is remembered for the next 100 ms by a sample-and-hold circuit. The latter either sets the level of a tone modulator for audio readout or else crosses a threshold for digital detection. At the end of the 100-ms interval, the output of the integrator is dumped by a shorting switch so that the next sample can begin. Note that the total independence of each sampling time interval disallows the "ringing" so common to very selective bandpass filters. Ringing is a condition of slow buildup and decay that can make a Morse signal sound so mushy as to be unreadable. The Petit filter is immune to ringing.

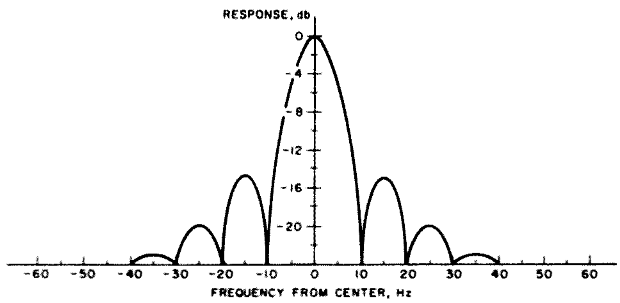

Fig. 2. Petit filter response curve (originally appeared in CQ*, June, 1977).*

The selectivity curve of the Petit filter is shown in Fig. 2. It does have side lobes that are still fairly high, although they remain quite close to center frequency. These side lobes might be diminished or eliminated by using other kinds of filters or by modifying the Petit filter. They are partly the consequence of the assumption in the design of the Petit type of filter that the Morse digital information is In pulses with zero rise and fall times—an inaccurate assumption.

Bandwidth may be adjusted easily by changing the sampling time interval. For instance, 1-second dot intervals will produce a bandwidth of only about 1 Hz, pulling signals out of the noise in a most impressive manner.

Signal-to-Noise Improvements

Some taped samples of 80-meter signals received by W3QVC and lab tests by W7GHM using the Petit filter are available for loan/purchase/copy from W3QVC at a minimal cost.

On an abstract numerical basis, signal-to-noise ratio is inversely proportional to receiver bandwidth. Thus, a 10-Hz-wide channel would give a signal-to-noise power advantage of 210 times (23 dB) compared to a 2100-Hz channel (a typical bandwidth for SSB voice communication).

In practice, the human ears and brain allow a degree of concentration on

the single tone of a CW signal that is the equivalent of a much narrower bandwidth than the wider filter would indicate alone. This effect has varying evaluations. One estimate (Woodson, *QST*, May, 1981) is that "this skill is worth at least a 6-dB margin when using a 2300-Hz filter. QRM, however, is often a confusion factor and therefore causes more degradation of copy than an equivalent amount of random noise. These psychological factors are difficult to quantify, but probably reduce the advantage of CCW over ordinary CW."

Woodson then gives comparisons of CW and CCW at different power levels in 14-MHz communications in 1975 between JR1ZZR and W6BB. Both modes were taped simultaneously on separate stereo channels and each channel was played back to four moderately experienced CW operators. The conclusion saw "an estimated 13-W CW signal as equivalent to a 0.1-W CCW signal in communications effectiveness, or a 24-dB superiority for CCW." (He should have said "21 dB" for that power gain.)

The taped laboratory experiments of W7GHM indicate that a CW signal 5 dB below the white noise level using a 500-Hz filter is just barely audible and only occasionally readable. The addition of a 10-Hz-wide Petit filter brings it to an easily copied level at what Petit describes as a "signal-to-noise ratio of 12 to 15 dB."

When Petit then drops a signal 14 dB below the noise and changes his filter to only 1-Hz bandwidth, the results are truly astonishing. The signal goes from completely lost in the noise up to 15 dB above the noise—a gain of 29 dB!

Frequency Stability

A narrowband system can work only if its overall frequency stability is within its bandwidth. Channels 10 Hz wide will tolerate errors of only a few Hz. Two factors affect frequency stability: (1) phase changes due to variations in the propagation characteristics of the medium through which the wave is sent, and (2) the accuracy of the frequency-control systems for the transmitter and receiver.

Phase changes during propagation set an almost absolute limit to the narrowness of the bandwidth that can be used. How could we imagine, for instance, that a VHF signal broadly modulated by the undulations of aurora reflection could be contained within a 10-Hz channel?

So far we do have some experience with CCW in long-distance HF communication. Woodson says: "For 14-MHz signals, motion in the F layer typically produces 2 or 3 Hz of phase (or frequency) modulation for a JA to W6 path. (We have also observed what appears to be propagation time delays under poor band conditions.)" Woodson goes on to speculate about VHF applications: "CCW might be used for EME communication, but the problem is complicated because of lunar-motion Doppler effects. One might need a computer to calculate the frequency at which the signal is expected to return."

A more practical solution to the Doppler problem with satellite repeaters might be reached through tight phase-locking to the satellite beacon signal, followed by computerized selection of the receiver frequency for a given transmitter. Even this would involve the solution of a complex puzzle.

VHF experimenters will have to discover what atmospheric conditions will allow the practical application of CCW to the VHF and UHF bands. Exactly what phase shift is introduced in tropospheric propagation? Can frequency modulation be confined to 2 or 3 Hz? On what bands, under which circumstances?

Questions like these, with answers not yet available, determine the ultimate possible narrowing of bandwidths. But the picture is less cloudy, indeed hopeful, when we consider the area of equipment frequency control.

Secondary Frequency Standards

The accepted frequency accuracy for HF CCW equipment is one part in ten to the seventh power. This allows for an error of not more than 1 to 2 Hz in either the transmitter or the receiver—adequate for 10-Hz bandwidths. The required precision is met by carefully constructed room-temperature oscillators with temperature compensation through suitable capacitors across the crystal.

VHF CCW calls for at least an order of magnitude of improvement in frequency accuracy. Frequency standards dependable to one part in ten to the eighth are not so simple. They use excellent crystals and both crystal and oscillator are enclosed in two concentric proportionately temperature-controlled ovens. The one ray of hope for amateur use of these standards is that they are available on the surplus market from time to time, currently costing about $75.

The setting of the exact frequency of such a standard is also a problem—but not unsolvable. HF propagation phase shift makes WWV unusable for most people for standardizing frequency to better than one part in ten to the seventh. Higher accuracies can be obtained from one of three comparisons: (1) with WWVB at 60 kHz, (2) with Loran C at 100 kHz, or (3) with TV network colorburst signals.

Comparison With Primary Standards

Don Gross has developed a receiver that allows the signal from WWVB to gate a frequency counter. The frequency of his secondary standard is multiplied by ten, resulting in a 10-MHz wave to be counted. By using 100-second gate times, his standard can be measured to parts in ten to the ninth. Counting errors are typically only 1.4 digits (or 1.4 parts in ten to the ninth) during the midday hours when 60-kHz propagation is most stable. The addition of a voltage-variable capacitor to the frequency standard allows easy trimming adjustments to a part in ten to the ninth. Drift is so slight that such trimming is needed only two or three times a week.

Such high accuracies are possible when WWVB is received on a good balanced and shielded loop antenna and when the receiver bandwidth is narrow enough to provide a good signal-to-noise ratio. The Gross receiver converts the 60-kHz signal to 1.11 kHz, where it passes through an N-path filter only 0.1 Hz wide. It is then re-converted to 60 kHz, limited and zero-crossing detected, then frequency divided to provide the counter gate control. Both the down- and the up-conversions use heterodyning frequencies derived from the secondary standard.

Bert De Kat has developed an effective and fairly simple method of measuring frequency by using Loran C. He uses a switch-controlled frequency-divider system to derive from his secondary standard the pulse repetition rate (PRF) of any Loran C station. (This divider is derived from Fig. 7, Burhans, *73*, May, 1978, ignoring the slave window timer.) He sets his PRF to

coincide with the nearest station and uses this locally-derived signal to trigger his oscilloscope. A broadbanded 100-kHz shielded loop and amplifier provide the Loran C signal to be displayed on the scope. By switching to a one-digit miscount in the divided frequency, the position of the display can be slowly moved across the screen until it reaches a suitable spot; the count is then corrected and the waveform stays in position. By using a high-grade oscilloscope, it is possible to expand any small portion of the 100-kHz waveform. By choosing the third zero-crossing of a pulse being built up, it is easy to keep track of the length of time that part of the wave moves across a measured part of the screen. This information can be used to measure the phase drift of the secondary standard. This measure is highly accurate, since the chosen part of the waveform is purely ground-wave and therefore stable in its propagation. Frequency is readily measured in parts in ten to the ninth or better.

Other methods of precise frequency measurement are covered in the bibliography.

Frequency Synthesizers

Since every frequency and timing element must be accurately controlled, high-quality frequency synthesizers are important. Ray Petit has done outstanding work in this direction. Although the bibliographic references to his synthesizers do not represent his latest developments, they show examples of excellent equipment that can be used to tune in either 100-Hz or 10-Hz increments, all phase-locked to the secondary frequency standard.

Keyers

The keyer that lends itself especially well to the timing requirements of CCW is the Accu-Keyer described in many issues of the ARRL *Radio Amateur's Handbook*. The oscillator part of this keyer is eliminated. A 10-Hz square wave derived from the frequency standard is connected in its place. This same 10 Hz is sent to the clock input of two D flip-flops: The Q output of one of these goes to the dot input of the keyer; the Q output of the other provides the dash input. The paddle (preferably a dual squeeze type) connects to the D inputs of the flip-flops. Debouncing can be arranged by connecting a resistor from each paddle output to the keyer positive voltage and a capacitor from each paddle to ground. CMOS versions of the Accu-Keyer are easily constructed and they are advantageous. The result of this circuit modification is a keyer that follows the desired CCW timing cycle to perfection.

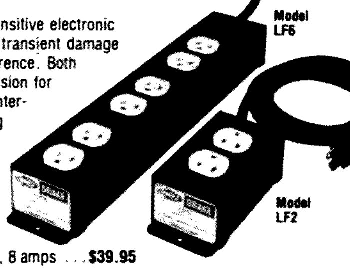
Computerized keying is becoming increasingly popular. Some commercial keyers can be modified for the external timing and phasing required for CCW; others cannot. W3QVC had hoped that his M-80 Morse program for his TRS-80 would be adaptable to CCW. Although its keying speed can be fine tuned, its phase cannot be linked to the secondary frequency standard. As a result, with much that has been learned from volume 4 of the *Disassembled Handbook for the TRS-80* mentioned in the bibliography, he is encouragingly engaged in the production of a machine language Morse program for the TRS-80 (either Model I or Model III) that can use external clocking derived from his frequency standard.

Conclusion

CCW is just beginning to make its mark in amateur radio communication. With all the technological advances now at hand, there is every reason to consider the possible usefulness of CCW in the VHF range. There is plenty of room for new experiments! ■

POWER•LINE FILTERS

These filters protect any sensitive electronic equipment from power line transient damage and radio frequency interference. Both models offer surge suppression for power line "spikes". RF interference is suppressed using both inductive and capacitive components. Ideal for computers, test equipment, or TV.



LF2—A duplex outlet, 120V, 8 amps . . . **$39.95**

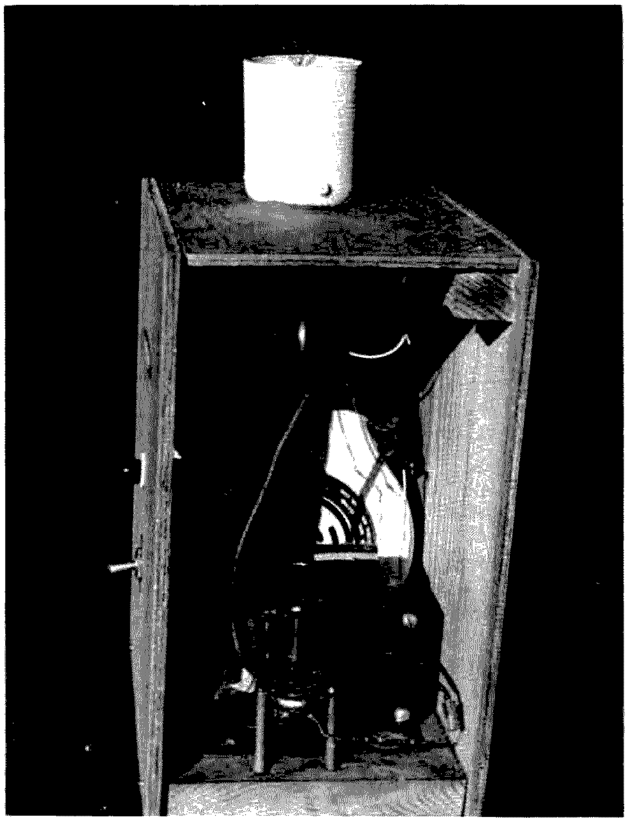
Electric Health via Negative Ions

— combatting an invisible menace

Scientists studying "ill winds" have unearthed some amazing facts. First of all, there really *are* ill winds, air masses that produce nervous and physical symptoms in weather-sensitive people.

In our country, these symptoms have long been considered purely psychological, or just in one's mind, but in other countries such as Germany and Israel, they have long been related to bad winds, the Foehn in Germany and the Sharan in Israel.



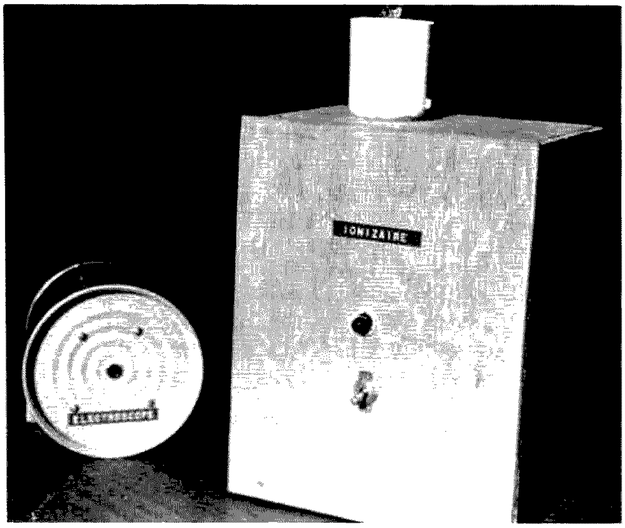
Inside the ion generator. Old hair dryer (without heating elements) is used to disperse ions.

Scientists have found that these air masses produce measurable changes in our bloodstream. And they believe they have found out how.

It seems that even before these winds sweep across an area, the positive ionization of the air increases enormously. In normal air, for every four negative ions there are five positive ions.

These positive ions in some way seem to increase the serotonin in the blood. This is a hormone whose properties are just now being investigated. Already we know serotonin has a great deal to do with our nervous condition, our moods, etc.

Before the ill winds come, the positive ionization of the air increases over 3000%. It's no wonder, then, that people can be affected. Doctors in Israel



Complete negative-ion producing and sensing system.

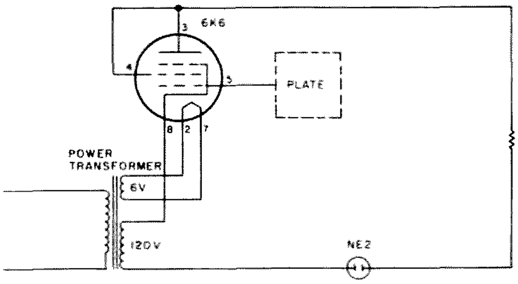


Fig. 1. Schematic of negative-ion-sensing electroscope.

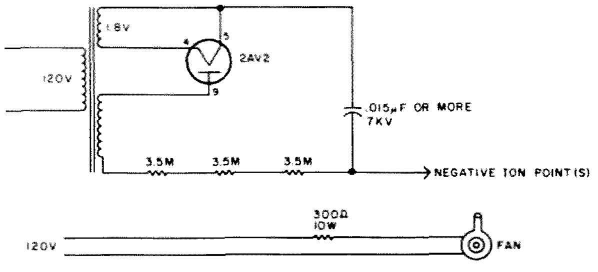

Fig. 2. Negative-ion generator.

often treat the nervous and physical ailments of their patients at these times by drugs that inhibit the action of serotonin, with almost magical results; moods change dramatically.

In our country, we also have such ill winds: the Santa Ana in California and the Chinook of the Rocky Mountains. You have perhaps experienced the exhilarating effects of the air at the seashore, near a waterfall, or in the mountains. In such places, the *negative* ions predominate.

As we become more and more "civilized," we also live in more completely air-conditioned environments. This air-conditioning not only warms or cools the air, it often deprives it of most of its negative ions. Air pollution outside our homes has the same effect. Tobacco smoke, besides being offensive to many noses, also depletes our working and living environments of negative ions, thereby adding to our nervous tension, so we pull out another cigarette, compounding the felony.

The mood we are in while we work is important. The Federal Aviation Administration is even studying the possibility that the imbalance in positive/negative ion concentration in cockpits may contribute to pilot error, resulting in dangerous situations for all on a flight.

This new knowledge of our environment and how it affects us has promoted the rise of several companies producing negative-ion generators, on the theory that if we can change the ion balance in our living or working environment to favor the negative-ion concentration, it will result in better feelings and better work, as well as help purify the air.

Most of these companies are really trying to give us something for our money, but some do it better than others. Some ion generators produce mostly ozone, which is not the negative ions we want; in fact, it has been found detrimental to health.

Later in this article I will detail how you can build your own negative-ion generator. But first we should have a way of telling whether we are really getting negative ions or positive ions or just ozone. We can't *see* any of these. Ozone we can detect if our nose is in good functioning condition, but only our moods could tell us whether there are too many positive ions in our environment.

So, although we can produce our own negative ions, we need a method of detecting these helpful ions. What we need is a negative electroscope. You may be familiar with electroscopes used in high-school science classes, two-leaf affairs made of thin foil which separates when electrostatically charged. The difficulty with these is that they will react to either a positive *or* a negative charge. So we still are in the dark as to which ions we have generated, if any.

The Negative Electroscope

Fig. 1 shows how to build a simple *negative* electroscope which reacts to a concentration of negative ions. As you may know from your knowledge of vacuum tubes, a negative charge on the grid of a tube prevents current from flowing in the tube. In this circuit the grid is connected to a pick-up plate some five inches (13 cm) in diameter. When this plate is in a nega-

tive field (negative ions produce a negative field), it places this negative charge on the grid of the tube and the neon bulb in the plate circuit goes out, showing that current in the tube has been cut off by a negative charge on the grid.

Any triode tube may be used, or a multi-element tube with the screen grid connected to the plate (ignore other elements except filament, cathode, and grid). If the cabinet is made of wood or plastic, you don't need the isolation transformer. But be careful that no high voltage is on any external surface.

I found an aluminum plate from a discarded percolator to be about the right size. I mounted the neon bulb (with its resistor) in the ready-made hole in the center of this plate. Then it was simple to mount a small filament transformer and the tube socket to the back of this plate. I didn't use an isolation transformer as only the plate connected to the grid can be touched from outside, and it has only the voltage of the surrounding air.

Usually the neon bulb will be on because the ordinary air conditions are positive, which allows some plate current to flow. Touching the plate will sometimes cause the neon to go out, but more often than not it will light brighter. You can experiment with this electroscope by combing your hair and bringing the comb next to the plate or walking across the carpet towards the plate. As you will find, most of the static charges produced are of a positive polarity and will make the neon glow even brighter.

The Negative Ionizer

To build the negative ionizer (Fig. 2), I bought a surplus 6-kV transformer, formerly used for a bug-killer. If you have an electronic background and don't mind the size of your ionizer, there is an alternative to a high-voltage transformer. If you have an old working TV set, you could, with some wiring changes, bring out the *negative* high-voltage lead of your TV flyback power supply and use it to generate your negative ions. The anode lead going to the picture tube is positive. In front of the ordinary TV set you will find an overabundance of positive ions. Perhaps this is partly the cause of our moody reaction to television!

I used an ordinary 2AV2 tube for rectifying the high voltage. If you have some very high-voltage diodes, these could be used, but they are not as tolerant of sparks and corona discharge as tubes are.

Build the whole ionizer in a wooden or plastic case or insulate heavily—five or six kilovolts is lethal! The extra 10-megohm resistor (actually three 3.5M resistors) is in the positive lead to ensure that anyone coming into accidental contact with the cathode, or negative-ion lead, will not be seriously shocked. According to Ohm's Law, this 10M resistance would allow about 0.7 mA of current to flow. You probably get much more than this in the thousand-volt shock you get by walking across the carpet and touching someone.

Despite this 10M precaution, shield the negative-ion point or cluster as well as possible from prying fingers. Be sure to keep the whole apparatus *out of reach* of children altogether. The shock that one can get from this ionizer is not serious but could easily produce a jerk of the arm that could upset and knock down the ionizer with more serious consequences. As when you open the back of your TV set, the best advice is: Don't! And the next best is: Know what you are doing and *be careful!*

The capacitor I used to store up the 6-kV charge was the 0.015-μF capacitor that came with the bug-killer. To build a better charge, a higher capacity could be used here (but be sure it is a high-voltage type). With the 6 kV, I had some trouble with arcing and corona discharge at the tube socket. The 10M resistor helped reduce this, and some anti-corona spray made it manageable. The corona discharge usually produces positive ions, so it is undesirable.

I first made the negative discharge element a point (a filed-down iron nail), but later added some extra points to increase the discharge. Perhaps you would like to use a piece of copper mesh such as is used in cleaning utensils. In any case, try to shield this in some way or keep it out of reach of children.

I found the 6-kV bug-killer transformer had enough space to wind a few extra turns on, to light up the filament of the 2AV2. If you can't do this or decide to use another rectifier, a separate transformer could be used for the filament. One advantage to using a high-voltage diode would be the saving of this extra transformer.

I also enclosed in my box an old hair-dryer blower (the heating element had burned out). In series with this I connected a 10-W resistor to slow it down a bit. In this way I had a slight breeze blowing up out of the ionizer to disperse the negative ions generated. But this is a refinement that may not be necessary.

"An ill wind blows no one good" says an old adage. Build this ionizer and be prepared to combat this invisible menace.■

The Very, Very Best CW Filter?

—costs under ten bucks

With dozens of published designs for audio filters, and with thousands of electronics engineers sitting around sipping wine and admiring their diplomas, however in the name of Hiram Percy Maxim do a couple of kitchen-table tinkerers get off calling this "The Very, Very Best CW Filter"? What makes this one worth your attention?

Well, for openers, we've got four aces:

- It works. (Slicker than a politician on the day before election.)
- The price. (How does less than $10 sound?)
- Adjustable bandpass. (Continuously adjustable from less than 30 Hz to full-open. That represents a Q of 25 down to a Q of nothing.)
- It's simple. (*You* can build it in less than an hour. You don't have to understand—just follow the pictures and the instructions.)

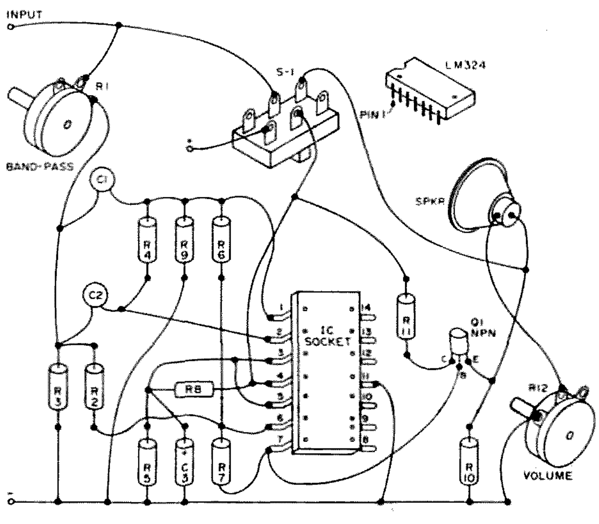

Fig. 1.

So if you're tired of crackles, pops, roars, whistles, and worse yet, interfering stations, this is the gadget for you. You can dial them out almost like magic!

The filter uses only one integrated circuit, the LM-324 quad op amp, which is available at Radio Shack for about $1.50. Also required are some resistors and capacitors, a speaker, and a power supply (batteries will do). If you'd rather travel by Cadillac than skateboard, add a phone jack and construct a power supply as shown in Fig. 3.

The design is nothing new—as a matter of fact, it is based on a filter design shown in the spec sheet for the LM-324. We have added to the design to provide for an adjustable bandpass, and we have tried to write simple directions for construction. Those who are experienced builders are not likely to need or follow our instructions, so we are writing for the person who has never, ever even seen an integrated circuit.

Decisions, Decisions, Decisions

OK, if you are convinced that you can live no longer with QRM and QRN, it's time to make some decisions.

(a) What kind of cabinet? How about a cigar box; maybe a small plastic box; or try one of those small metal card-file boxes from the stationery counter at Woolco.

(b) Chassis—Experienced builders will probably use perfboard or printed circuits, but beginners will probably do better with a small piece of plywood, about 3" × 5". Use small nails for terminals or tie-points, preferably soldered.

(c) Power supply—The operating voltage can be anything from 5 to 14 volts. The unit draws 120 mA at 9 volts. An ordinary 9-volt transistor radio battery will give about 4 hours continuous service, but four C or D cells in series will last several hours longer. (Later we will discuss the elimination of the transistor post-amplifier. Without the transistor, the unit draws only

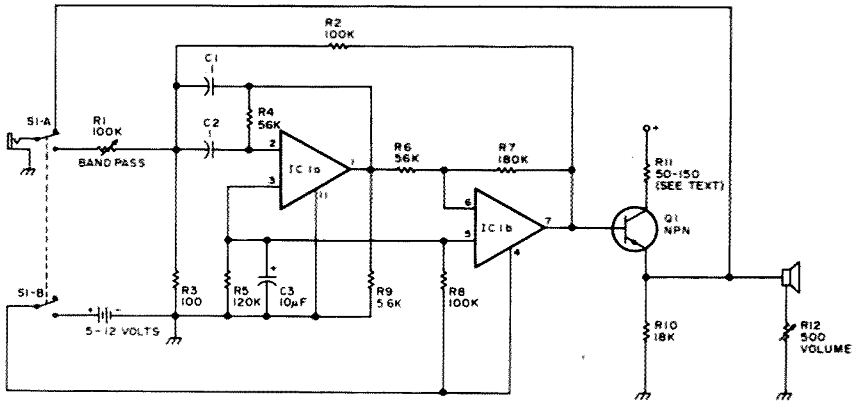

Fig. 2.

20 mA at 9 volts. Your battery would last a long time assuming you remember to turn off the power when the unit is not in use.)

If you opt to construct a power supply to operate from house current, try the one in Fig. 3. It's simple and inexpensive.

(d) Phones, speaker, or both?—The design shows a speaker within the unit, but if you feel you might want to use phones, install a phone jack. Sorry, we can't draw a picture for this; there are just too many types of phone jacks. Consider, though, that the output of the filter is at a constant volume regardless of the input. Many times you will hear a signal at full volume that you cannot hear at all with the unaided ear. You don't have to depend on phones to pick out the weak ones.

(e) Center frequency—This unit should have a center frequency (in its sharpest mode) of about 700 Hz. That is, *if* capacitors C1 and C2 are actually 0.1 uF. Unfortunately, capacitors are flighty things; the actual capacitances are almost never the same as the marked capacitances. So, "ye pays yer money, and ye takes yer chances." More likely, the center frequency will be about 5% to 10% below the designed center frequency. If you would like a different center frequency, the Design Notes give alternative component values.

About Construction

The LM-324 looks like a fat centipede. Pins are numbered counterclockwise beginning to the left of the notch when viewed from the top. (Remember, George, that's clockwise when viewed from the bottom or pin side.) Most ICs also have a small dot marking pin 1. If this is your first IC project, invest six bits in a 14-pin wire-wrap IC socket (that's the one with the long pins). It'll save a lot of cussing—believe it!

The bandpass control (R1) may be 50k to 100k Ohms. The filtering is sharpest when R1 is set at a high resistance, and when R1 is very low, the bandpass is so wide it seems there is no filter at all. When R1 is at 80k Ohms or higher, the bandpass is less than 4% of the center frequency, which is too narrow for ordinary CW use. Most noise disappears when R1 is set at about 30k Ohms, and a setting of 50k Ohms will narrow the bandpass to less than 40 Hz.

Make your connections to the power switch (S1) so that when the power is off, the signal is bypassed around the unit direct to the speaker. See the illustration in Fig. 1.

The transistor used as a post-amplifier needs to have a power dissipation rating of better than 1.5 Watts. The 2N2222 can handle this, but if you substitute another NPN, check it after a couple of minutes of use to see if it is heating too much. You may control this by putting 50 to 150 Ohms resistance between the plus voltage terminal and the collector of the transistor. (This is shown in the drawing as R11. Naturally, if the transistor you use can handle the power without overheating, you may eliminate R11.)

PARTS LIST
(All resistors ¼ Watt)

R1	50k Ohm to 100k Ohm variable resistor
R2, R8	100k Ohms
R3	100 Ohms
R4, R6	56k Ohms
R5	120k Ohms
R7	180k Ohms
R9	5.6k Ohms
R10	18k Ohms
R11	50 to 150 Ohms (see text)
R12	500 Ohm variable resistor
C1, C2	.1 uF
C3	10 uF
C4	1000 uF
Q1	2N2222 or equivalent NPN transistor (see text)
IC1	LM-324 quad op amp integrated circuit
S1	Double-throw, double-pole slide switch

Small speaker
Battery (see text)
For optional power supply see Fig. 3.
IC socket 14-pin wire wrap

The LM-324 filter produces reasonable volume into a small speaker without further amplification. If your shack is not noisy, simply connect one leg of your speaker to pin 7 of the LM-324 and eliminate transistor Q1 and also resistors R10, R11, and R12. The volume will then be enough to be heard clearly from a distance of 10 to 15 feet. (Remember the weak signals sound just as loud as the strong ones.)

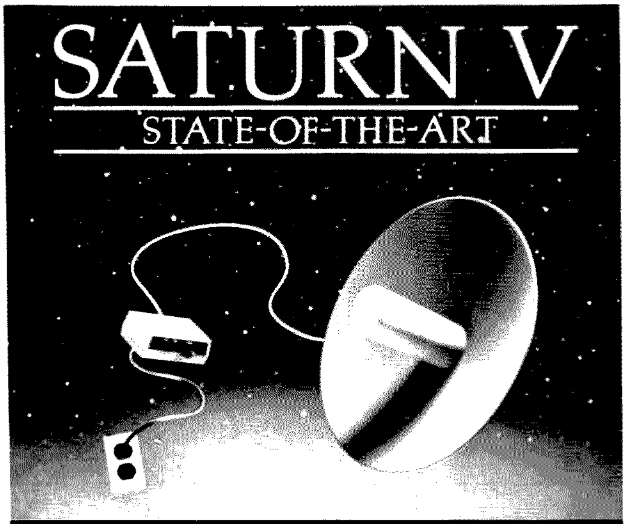
Using the Filter

Connect the input of the filter to the phone jack or external speaker connections of your rig. Turn R1 to

Design Notes
Desired Center Frequency

Component	710 Hz	816 Hz	850 Hz	1020 Hz
R4, R6	56k	51k	47k	39k
R2 (R4 × 1.5)	82k	75k	72k	62k
R3 (R4/623)	91	82	75	62
R5	120k	100k	100k	100k
R7 (R4 × 3)	160k	150k	150k	120k
R8	100k	100k	100k	100k
R9	5.6k	5.6k	5.6k	5.6k

(Computed to nearest standard values—R4 and R6 are considered critical. Other values may vary up to 25%.)



The Saturn V is a deep fringe microwave receiver for homeowners that are outside of the service area of local pay TV stations (i.e., HBO, Showtime). It is normally used within line of sight of a transmitting tower in a 50 mile range and is simply attached to your TV antenna mast. This unit is completely ready to install including all cable and mounting hardware. It is designed to be installed by the homeowner.

its lowest resistance setting. With the power on, you can hear both the desirable and undesirable as you tune across the band. When you have located the signal you want, narrow the filter by adjusting R1, bandpass control, until the undesirable is eliminated. (You may have to slightly retune your receiver as you tighten down on the filter, but you'll soon learn to recognize the center frequency and tuning will be fast and easy.) Keep the volume of the receiver as low as possible. If you get a chug-a-chug sound, you're using too much volume. Remember, the filter will pick up some signals when the volume is turned so low you can't hear them ordinarily.

We've tried to keep it simple—so if you're too tired to build this yourself, give this article and the parts to one of the kids. ■

Editor's Note

Shortly before publication, *73* learned that R5 should be changed to 68k for best performance. Please note this change.

The True-Blue Keyer

—its speed readout doesn't lie

Editor's Note: The 8044 keyer chip used here is available from Curtis Electro Devices, Box 4090, Mountain View CA 94040; telephone (415)-964-3846.

This article describes a project that started as a typical electronic keyer and ended up including a self-contained readout that displays words per minute (wpm). This keyer is unique because of its ability to digitally display the speed in wpm of the keyer IC before either the dot or dash paddle is closed. Additionally, it will display the sender's speed in wpm during a CW transmission. These features were designed into the project using all CMOS technology and mechanical coupling between the keyer and image clocks.

The project features common keyer controls such as speed, volume, tone, weight, sidetone on/off, and transmitter tune with added front-panel switches for display calibrate and image/keyer display.

Circuit Operation

The use of a calibrated, tracking image clock is the circuit's simple method of generating a clock frequency when there is no clock output from the keyer IC, as in a standby condition. When the operator starts sending CW with the paddles, the logic circuitry transfers the wpm display from reading the image clock to reading the keyer clock. The display is updated every 1.2 seconds and will show the correct wpm after the first two update periods. A lower CW speed than the preset level will register if the operator is not sending at the proper rate and with the correct spacings. This feature provides visual feedback, telling the operator if his fist needs some correction. The display will never show a wpm level in excess of the preset value no matter how fast the paddles are actuated because the counter records only the number of clock pulses for 1.2 seconds generated by a particular frequency (speed) selected by the speed control.

Upon completion of the last CW character and, hence, the last keyer clock pulse, the display will show a reduced wpm or even zero for a short interval. Again, the logic functions and the display shows the output of the image clock.

Display keyer.

Circuit Description

The display keyer can best be described by separating it into three sub-circuits. The block diagram of Fig. 1 shows these circuits in their simplest form for those interested in following the logic sequence.

The heart of the system is the 8044 IC. This sub-circuit is shown in Fig. 2. Generally, I used the published circuit* with a few modifications. As shown in Fig. 2, these mods were not major circuit changes but just use of what the 8044 had to offer. For instance, the dot and dash terminals (pins 2 and 7) are normally high during standby. This was used very conveniently to drive the Exclusive NOR, U4a, a CD4077. Another connection to pin 8 of the 8044 was used for clock frequency pick-off to drive the counter and display circuit (Fig. 4) via an FET bilateral switch, U5a, 1/4 of a CD4066.

Another switch, U5c, was wired to the base of the 2N1613 driver transistor. This FET switch grounds the base of the driver transistor when U4b, pin 11 (Fig. 3), is high, thereby preventing the transistor from being keyed during clock calibration.

The output keying transistor, a 2N4356, is configured to drive a grid-block input circuit. Choice of this transistor will depend on your transceiver's grid-

*8044 Keyer Data Sheet, Curtis Electro Devices, Inc., revised February 23, 1979.

block voltage. My HW-101 presents −50 V dc at the key jack, so this transistor with its BVceo of 80 V dc has an adequate margin.

The final mod to the keyer circuit was the addition of the dual, 500k single-shaft pot. The keyer clock is controlled by R1A, while R1B (Fig. 3) controls the image clock frequency. Use of this dual pot mechanically couples the two clocks together to provide proper tracking and the correct wpm display during standby conditions.

The second sub-circuit is shown in Fig. 3. All of the switching and timing functions are controlled by this circuit. The positions of FET switches U5a and U5b as well as SW1 and SW2 are in a standby, ready-to-transmit mode. The logic states of the CD4077 that are useful for this circuit are L+L=H, H+H=H, H+L=L. The following logic states exist for Fig. 3 as shown. U4a pins 1 and 2 are high, thus pin 3 is high. U4c pin 6 is high and pin 5 is low, thus pin 4 is low. U2 is wired as a positive retriggerable monostable. With U2 pins 8 and 12 low, pin 10 will be low. U4d pins 8 and 9 are low, thus pin 10 is high. U4b pin 12 is high and pin 13 is low, thus pin 11 is low and U5c is open.

During standby conditions, the image clock, U3, wired as a free-running astable has its output pin 10 routed to the counter via the closed bilateral FET switch, U5b.

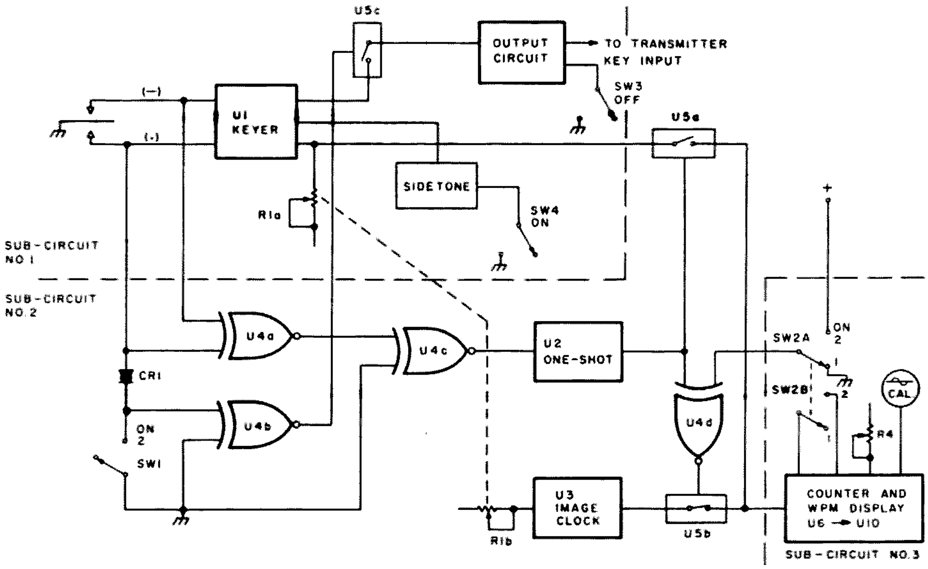

Fig. 1. Display keyer block diagram.

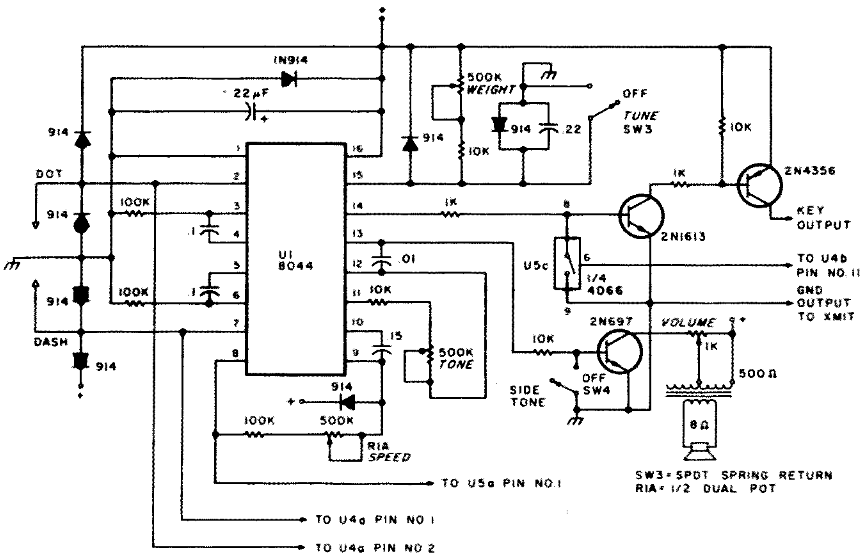

Fig. 2. Keyer and output circuits.

When a dot or dash paddle is closed, U4a's input state will become either L+H=L or H+L=L. As you can see, U4a's output will be forced low in either case. This low is inverted by the controlled inverter, U4c, whose positive output triggers U2. U2's monostable pulse width is set to four seconds by the 1 meg and 1µF RC combination. This pulse width was selected to accommodate low-speed operation, which may include long pauses. If the pause is greater than the pulse width, the display will revert back to the image clock. As long as this condition exists, the display will continue to show random numbers as it bounces between the two clock outputs. U2 pin 10 will remain high for positive retrigger pulses arriving at its input within the four-second on-time. U4d pin 8 now remains high, which forces pin 10 low and opens U5b. The high on U2 pin 10 also controls U5a, causing this switch to close and routing the 8044's clock output to the counter and display circuit. The display now registers the wpm of the transmitted CW up to the maximum set by the speed control.

The logic transfers just described will remain in effect until there is a pause greater than four seconds. Upon completion of the last paddle closure, either a dot or a dash, U2 is retriggered for its last cycle. After four seconds, all logic states will revert back to the standby condition, with the display showing the image clock wpm. During this transition, the display may show a double-zero indication because there is no clock output from the 8044 and U2 has not returned to zero on pin 10, closing U5b and opening U5a.

The image clock, U3, uses R1b for setting the clock output on pin 10.

Rcal is a 100k multi-turn trimpot required to calibrate the image clock so that it will properly track with the 8044 clock.

Fig. 4 shows the third subcircuit, the counter and display. Credit for this circuit goes to Howard F. Batie W7BBX whose fine article, "QRQ, QRS—By the Numbers," appeared in the June, 1980, issue of *73 Magazine*. The circuit description is throughly covered in this article, so further explanation would just duplicate his effort.

Dc power for all circuits is produced by an internal regulated power supply (Fig. 5). The 7808 three-terminal 8-V dc regulator was selected because it provides at least two volts of Vdd margin for the 8044 IC. This IC is rated for 10 V dc maximum while all other CMOS used have a 20-V dc rating. The 7808 is rated for 1 Ampere steady-state load. The circuits in this project can draw 200 mA, which is well within the 7808 rating, but the regulator must be bolted to a heat sink or it will destroy itself. The regulator's mounting tab is its ground terminal and therefore can be electrically attached to the chassis.

Calibration

The following description is based on all switches positioned as shown in Figs. 2, 3, and 4 and the paddles are open.

After ac power is applied, I suggest a warm-up time of five minutes. If all circuits are working properly, the display should indicate a two-digit number.

The 8044 IC is capable of 8 to 50 wpm with the values shown. The image clock was calibrated using Rcal and a speed setting of 30 wpm. This provides tracking within 1 to 2 wpm from 8 to 30. Above 30 wpm, I experienced difficulty in getting proper tracking because of nonlinearities in the image clock. If the speed control is advanced above 30, the image display will increase very rapidly and show a false number. At these higher speeds, with the paddles open, a momentary indication of the correct speed is available when the front-panel clock switch is transferred to the 8044 position. During CW transmission, the display will read correctly for any speed over 30 wpm.

SW1 is an SPDT spring-return switch used during calibration of the image clock

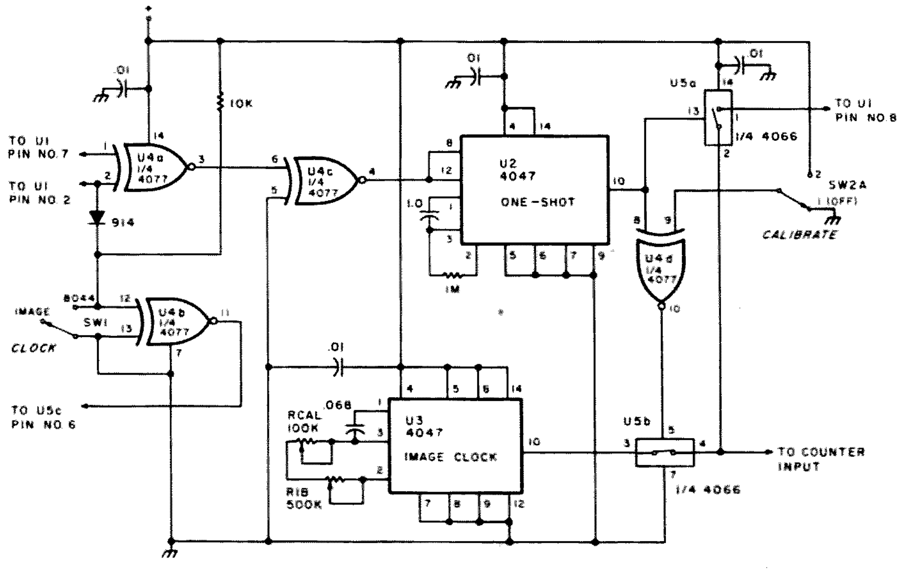

Fig. 3. Display sequencing logic.

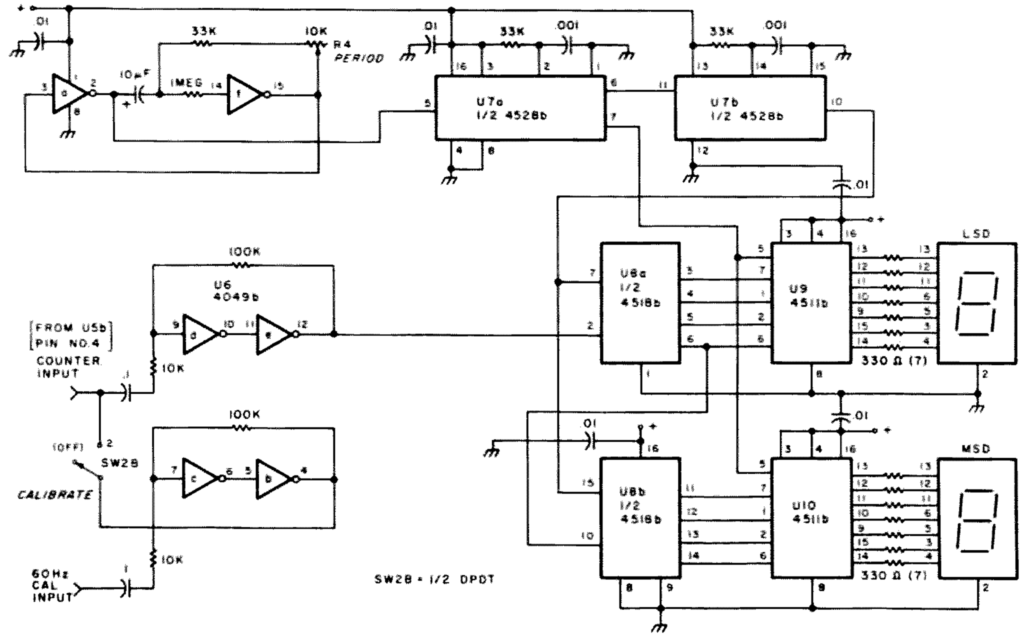

Fig. 4. Counter and wpm display circuit.

to match the 8044 clock. When SW1 is closed, the high on U4b pin 12 via the 10k pull-up resistor is grounded. This does two things: First, the 8044 is turned on through the 1N914 between U4a pin 2 and U4b pin 12. Second, U4b pin 11 goes high, which closes U5c, preventing any transmitter keying during clock calibration. The image clock could be calibrated by simply closing the dot paddle, but this is not recommended because the transmitter would be keyed unnecessarily.

SW2 is a standard DPDT toggle switch used to change the logic state on U4d pin 9 for counter period calibration. A high on pin 9 and a low on pin 8 will force U4d pin 10 low and open switch U5b. With switches U5a and U5b open, the counter input is open and ready to accept the 60-Hz calibration signal.

The counter circuit calibration uses SW2b to connect U6b pin 4 to the input of U6d pin 9. The remaining counter and display circuitry was used as it appeared in W7BBX's article.

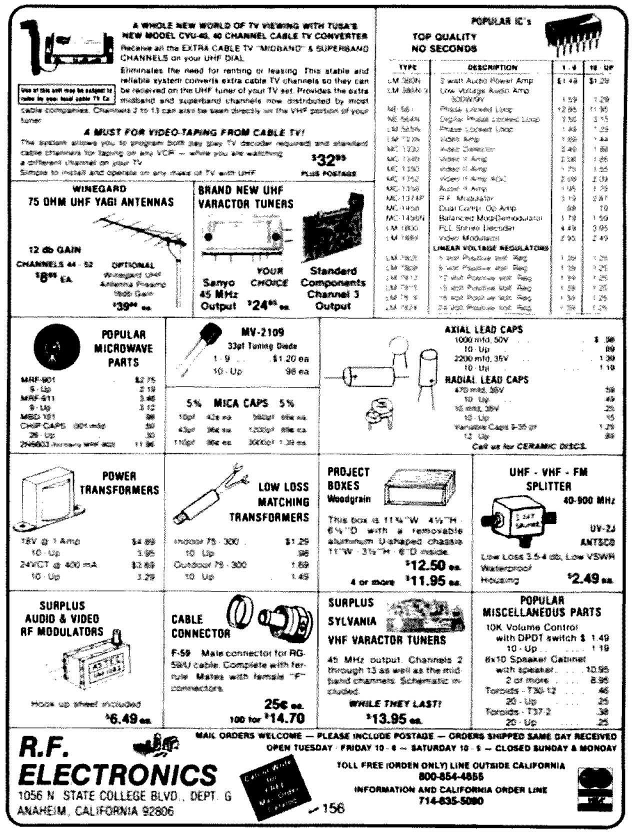
The first calibration step is to set the period, or gating time, of the frequency counter. This time period is controlled by adjusting R4 in Fig. 4. Incidentally, I recommend that a multi-turn trimpot be used for R4 to reduce the sensitivity of this adjustment. The calibration source is a low-voltage 60-Hz signal from the transformer secondary. With 60 Hz and a 1.2-second gating period, the wpm calculates to be 72. Therefore, with the front-panel Calibrate switch (SW2) up, R4 should be varied until a steady reading of 72 registers on the display. Remember to rotate R4 slowly, allowing the counter to count all the pulses during the gating time. When this step is complete, return SW2 to the down position.

The second calibration step involves setting the output frequency of the image clock to coincide with the 8044 clock at 30 wpm. Pressing the front-panel Clock switch (SW1) presents the 8044's clock to the counter/display circuit and registers it directly in wpm. The idea here is to adjust the 100k trimpot, Rcal (Fig. 3), so the image clock matches the 8044 clock. Next, release SW1 and adjust Rcal for the correct wpm. Rotate the Speed control (R1A/B) counterclockwise and check for proper tracking at lower settings.

This completes the calibration for the display keyer and only leaves the remaining keyer controls, which are self-explanatory.

Component layout isn't critical. For ease of fabrication and checkout, I constructed the counter/display circuits on one perfboard and the keyer with switching/timing logic on another. The power supply is mounted to a third perfboard with the 7808 near the center. The regulator's metal heat sink is connected to the rear chassis wall.

The display keyer project was fun to design and build and with its completion has added another dimension to my CW operation. The usefulness of the wpm readout has proved to be more than expected, with its constant reminder of CW speed. Besides being useful on the air, the project makes an excellent CW practice machine. The trainee can develop and improve both his speed and coordination using the display and sidetone as indications of his sending quality. ■



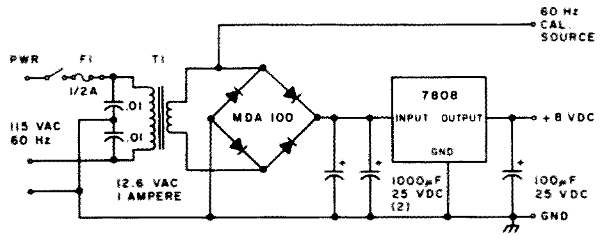


Fig. 5. Power supply.

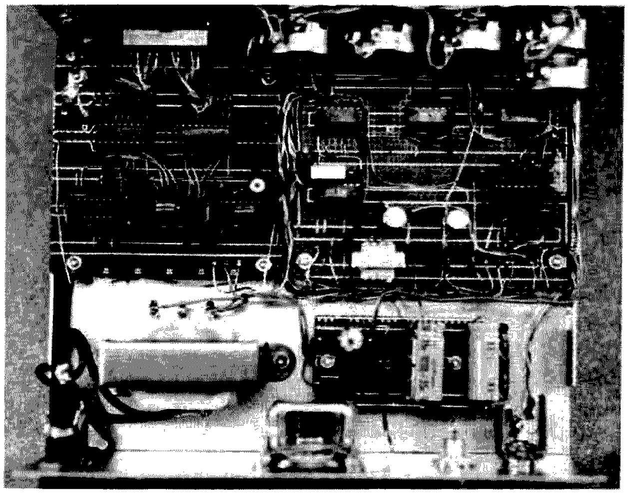

Top view of the display keyer, showing the three perfboards. Speaker, ac fuse, input and output jacks are on the rear panel.

I have been looking for a good program to make it possible for me to use my TRS-80 computer to send CW over the air. I wrote this one, with the following features:

- The transmitter is keyed through the cassette auxiliary plug and does not use the TRS-80 relay.
- Input and output speeds are independent so that you can type well ahead of what is being transmitted.
- The output speed can be increased or decreased at any time by holding the shift key and pressing the up or down arrow key.
- The input is displayed on the screen and can be edited before it is sent out by using the backspace key.
- The character being output is indicated by being removed temporarily from the CRT display, with the dots and dashes displayed in its place as they are sent. Afterwards the character is replaced. This goes on simultaneously with the addition of new characters. You always know exactly where the sending routine is operating.
- Messages can be typed out on the screen, edited, and then stored for later output. When called, the entire message is instantly placed on the screen in the proper sequence and is treated exactly like text you are typing.
- Hitting the break key will clear the screen and the buffers and stop the output.
- The output is perfect machine code of whatever is put on the CRT, including proper spaces.

Operation

Using Edtasm or Tbug, make an object program tape and load it. Operation is extremely simple. Just start typing and anything you type will be displayed and sent.

If you want a faster output speed, hold the shift key and press the up arrow key. Each time you do this, the speed is incremented. To decrease the speed, use the down arrow key in the same way.

To store a message for later use, first press the @ key and then key 1, 2, 3, or 4. Type in your message (up to 256 characters), edit it,

```

```

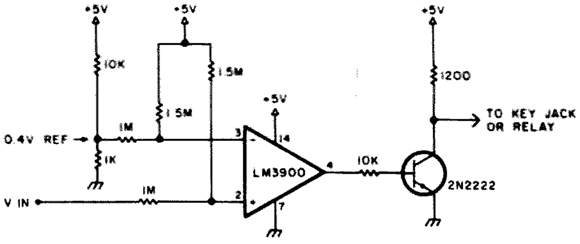

Fig. 1.

and after it appears on the screen just as you want it, press enter to store it. Up to four different messages can be stored.

When you want to send the stored message, hold the shift key and press 1, 2, 3, or 4 according to which message you want. The entire message will appear on the screen immediately after anything you have already typed in and will be sent in proper sequence when the output program gets to it.

Whenever you want to kill the output, hit the break key and you can start over.

The Program

The keyscan (02BH) subroutine in the ROM monitor contains a 17-millisecond delay. I had to rewrite this and put it in this program without that delay. Otherwise, typing in characters would mess up the output timing. Also, you will notice that I have used the keyscan subroutine as the major part of the timing loops for output of code. This is the trick that makes it appear that output and input are independent.

The output cursor is stored at 5000H and adjusted as necessary by using index addressing. The input cursor is handled by the monitor program.

The message routines were greatly simplified by making use of the subroutine in the monitor at 40H. All I had to do was put the start of the message buffer in HL. The subroutine then stores the message and

00000 TOTAL ERRORS
```

prints it on the CRT; at the end, the B register contains the number of characters in the message. This is saved to use when the message is called. The value is used by the LDIR routines which transfer the message to the sending buffer and to the CRT display.

I was tempted to go back and make the program more compact. However, that would make it more difficult to understand and to modify. To add more messages, you can use the ones in the program as a guide and add to the end of the program.

Interface

A schematic of a very simple circuit is presented which can be used to interface the computer with your transmitter. The tip of the cassette auxiliary plug changes voltage from 0.4 to 0.8 whenever OUT(0FFH), A with A=1 appears. This makes it possible to use a low-voltage comparator to drive the transmitter. I measured the current in this circuit at less than 10 mA for a +5-volt supply. Any supply voltage from 4 to 36 volts can be used. Be sure to pick the two resistors in the reference voltage divider so that the reference is just slightly larger than 0.4 volts. When V in is larger than this reference, the output of the comparator goes high and turns on the transistor and this will ground its output. That will key a solid-state transmitter or a relay if you need it.

Conclusion

This program has made sending CW a real pleasure for me and I know the guy on the other end appreciates the perfectly-sent code. The computer is put into service by just plugging in the cassette auxiliary plug—the one in the middle. Correspondence always a pleasure. 73.■

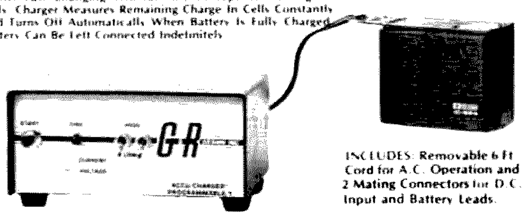
NEW FAST CHARGE
For Your Battery Packs

RECHARGE YOUR HAND HELD RADIO BATTERY PACKS TO FULL CAPACITY IN AS LITTLE AS 45 min. EXAMPLE—Fully Charge ICOM BP3 in 30-45 Minutes.

SEPERATE FUSES PROVIDED INTERNALLY FOR A.C. AND D.C. OPERATION. —BUILT IN REVERSE POLARITY PROTECTION.

ONE UNIT DOES IT ALL
Charge, ICOM, YAESU, KENWOOD, TEMPO, SANTEC and Others Automatically in Your Home, Car, Boat, R.V. or Airplane with Built-in Heavy Duty Power Supply or 12 to 24 V. External D.C. Supply Such as Cigar Lighter in Your Car.

All Solid State
Precision Components Used Throughout. In A Unique Circuit Allows Fast Changing Without Any Perceptible Heating Of Cells. Charger Measures Remaining Charge In Cells Constantly And Turns Off Automatically When Battery Is Fully Charged. Battery Can Be Left Connected Indefinitely



INCLUDES: Removable 6 Ft Cord for A.C. Operation and 2 Mating Connectors for D.C. Input and Battery Leads.

FEATURES: High Quality, Custom Designed Heavy Gauge Aluminum Cabinet.

FULL 1 YR. WARRANTY ON PARTS AND WORKMANSHIP

ACCESSORY CONNECTOR TO FIT ICOM BATTERY PACKS, BP-2, BP3, BP4, BP5, $3

DEALER INQUIRIES INVITED

TERMINALL

apple* + TRS-80*

TERMINALL is a hardware and software system that converts your personal computer into a state of the art communications terminal. Terminall features simple connections to your computer and radio plus sophisticated and reliable software.

Simplicity

TERMINALL was designed from the outset to be easy to connect to your radio and easy to use. Plug into your receiver headphone jack and copy Morse Code or radioteletype (RTTY). Plug into your CW key jack and send Morse Code. Attach a microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.

The software is loaded into your computer from disk or cassette. Enter your callsign and the time and you will start receiving immediately. No settings or adjustments are necessary to receive Morse Code, it's fully automatic, and it works! You may type your message while receiving or transmitting.

You will be on the air, receiving and transmitting in any mode, in minutes. As we said, TERMINALL is simple.

More for your money.

■ TERMINALL has the RTTY terminal unit, demod and AFSK built in. This results in a lower total cost.

■ **Fantastic Morse reception.** Six stage active filter demodulator copies the weak ones. Auto adaptive Morse algorithm copies the sloppy ones. Received code speed displayed on status line.

■ **Outstanding documentation.** Professionally written 90 page user manual contains step-by-step instructions.

■ **Built in, separate, multi-stage, active filter RTTY and CW demodulators.** No phase lock loops. RTTY demodulator has 170 and either 425 or 850 Hz shift keyboard selectable, and uses either the panel meter or scope outputs for easy tuning. Copy the weak ones. Copy the noisy ones. Copy the fading ones.

■ **Built in crystal controlled AFSK.** Rock stable for even the most demanding VHF or HF applications. A must on many VHF RTTY repeaters.

■ **Built in 110 or 220** volt AC power supply.

■ **Built in parallel printer driver software.** Simply attach a parallel ASCII printer (e.g. the EPSON MX 80) to your printer port to obtain hardcopy in all modes.

■ **Multi level displays** allows examining and editing of historical text.

■ **Word wrapping,** word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, multiple user defined WRU, transmit delay (fixed, none or auto adaptive), break mode and more!

■ **The all-in-one TERMINALL design** makes it great for use on HF or VHF Ham, Commercial, SWL or MARS! SWL's TERMINALL may be jumpered for either 425 or 850 Hz reception to copy news and weather services.

System Requirements

TERMINALL T1 Communications terminal for the TRS-80 Model I. Requires a Model I TRS-80, 16K RAM and Level II BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T3 Communications terminal for the TRS-80 Model III. Requires a Model III TRS-80, 16K RAM and Model III BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T2 Communications terminal for the APPLE II. Requires an APPLE II or APPLE II PLus with 48K RAM and disk. Software is provided on disk in DOS 3.2 format. Use MUFFIN utility to convert to DOS 3.3 format. Includes software on disk, assembled and tested hardware and an extensive instruction manual. **$499.**

The communications terminal that does it all!

CW—The Air Force Way

Staff Sgt. Ed Metzler
Keesler Technical Training Center
Keesler AFB MS 39534

Thousands of hams use Morse code every day to make contact with friends and acquaintances around the world, but Morse systems operators in the Air Force use the international code for a more serious reason.

"The people we train here will go to various installations around the world, mainly to assist in communications-gathering operations," said Major Emmitt D. Lane, chief of the Systems Operations Branch at Keesler Technical Training Center, Keesler Air Force Base, Mississippi. "Our operators monitor and transcribe radio communications at many locations, providing the Air Force with a secure communications security program."

It's a critical job in today's complex, ever-changing world and it's the job of the Systems Operations Branch to see that the Air Force operators are highly qualified for their responsibilities. The branch is under the command of the 3300th Technical Training Wing, the Air Force's electronics training center. At Keesler, airmen selected for Morse systems operator duty undergo an intensive 21-week course of instruction that is divided into three blocks of instruction. Students must be able to transcribe 20 groups of code per minute to graduate from the course, although the average graduate does about 25 five-character groups a minute.

To achieve this end, students spend approximately six hours a day, five days a week in the classroom. In block I, the students are introduced to international Morse code and typing.

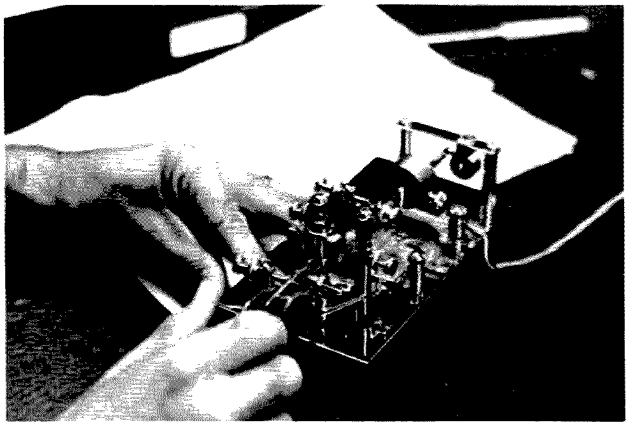
"We teach by the reflex method," said Cicero Rhodes, an instructor supervisor who spent more than 20 years in the field before retiring from active duty. "When the students hear the dahs and dits on their headphones, they automatically type the letter or number. After a lot of drill and repetition, it becomes second nature to them."

"Students learn the 31 characters during their first week of school," said Technical Sgt. Robert C. Templin, block I instructor.

Block I students are drilled on the basic characters of international Morse code.

A block I instructor uses the Vibroflex key to drill students before hooking into the distribution center.

A student in block III scans radio frequencies for message traffic.



A Vibroflex semi-automatic key used by instructors to drill students on individual characters.

"We combine learning the character sounds and typing. On day one, they learn the first finger characters as they appear on a standard typewriter, day two we teach second finger, and so on. By the end of the block, students are expected to copy 12 groups per minute."

Templin added that students who show effort, but have some difficulty learning the code, are set back in the course to bring their proficiency up. About 30 percent of the students, for one reason or another, do not graduate.

After learning the characters, the ditty-boppers, as they call themselves, work on their copy speed. As with learning the characters, this is done gradually.

"We start the classes at four groups per minute, then work up to 12," said Templin. "It's a matter of repetition and memorization." Codes are transmitted to the various classrooms by a closed-circuit system from a single distribution center. The center can send code in separate speeds to individual students or send uniform code to an entire class. The code tapes are made by the school staff, and unlike other branches of the military, are done by hand rather than computer. According to Rhodes, this personalized system allows for more individual attention.

In the basic block, students spend three to four hours a day copying messages from the distribution center. Some time is also spent in character drills. Using the Vibroflex semi-automatic key, an instructor can drill the 20 or so students in his class on particular problem characters or patterns before hooking up to the center.

In blocks II and III, students continue to increase their copying speed while learning other facets of the career field. In the intermediate block, students are taught radio wave and antenna theory and how to operate receivers. At the end of this block, students are able to copy 16 groups of code per minute. The last block deals with complex receiving using more than one receiver and locating copy on different frequencies. By the end of block III, students are expected to copy 20 groups per minute.

An instructor prepares a tape that will be used to broadcast from the distribution center.

"It's a very demanding course," said Sergeant Templin. "The material is very abstract. If someone is having trouble with a particular character, you can't just say, 'OK, turn to page 14 in the text and read all about the letter C.' It requires a person who isn't nervous or high strung, who won't get upset about every mistake he or she makes."

"Like anything else, it takes a lot of practice and patience," Rhodes emphasized. "How many tennis balls do you think you'd hit perfecting your backhand? Our methods aren't hit and miss, by any means, but I would say that repetition is the keystone to learning Morse code."

"I'm confident our methods work and that we are turning out very capable people into the field," said Major Lane. "We have to; our graduates fill some of the most critical positions in the Air Force."■

SOCIAL EVENTS

MILWAUKEE WI
JUL 8-11

The YL International Single Sidebander's (YLISSB) 1982 Convention will be held on July 8-11, 1982, in Milwaukee WI. Activities will include the DX Roundup, the Systems Awards Banquet on Saturday night, and a major door prize of an Icom IC-2AT. Jean Chittenden WA2BGE will tell about her recent China trip. Pre-convention activities will begin July 5, 1982, with golfing, fishing, and side trips planned. Detailed information may be obtained by sending an SASE (business size) to Sus Musachi KB9OC, PO Box 18123, Milwaukee WI 53218.

STATE COLLEGE PA
JUL 10

The Nittany Amateur Radio Club Ham Festival will be held on July 10, 1982, from 8:00 am to 4:00 pm, at the HRB-Singer picnic grounds, Science Park Road (between US 322 West and Rte. 26 East), State College PA. Talk-in on 146.16/.76, 146.25/.85, and 146.52. Features will include a flea market, technical sessions, numerous prizes and contests, and refreshments. Tickets are $3.00; tailgating and tables are $5.00. For more information, contact Richard L. Sine KB3WN 1600 E. Branch Road, State College PA 16801.

OAK CREEK WI
JULY 10

The South Milwaukee Amateur Radio Club will hold its annual swapfest on Saturday, July 10, 1982, from 7:00 am to 5:00 pm at the American Legion Post 434, 9327 South Shepard Avenue, Oak Creek WI. Admission is $2.00 and includes a happy hour with free beverages. Prizes include a $100 first prize and a $50 second prize plus a variety of other prizes to be awarded during the day. Parking, a picnic area, hot and cold sandwiches, liquid refreshments, and overnight camping will be available. Talk-in on 146.94. More details, including a map, may be obtained from the South Milwaukee Amateur Radio Club, PO Box 102, South Milwaukee WI 53172.

MILTON ONT CAN
JUL 10

The Burlington Amateur Radio Club will hold the 8th annual Ontario Hamfest on Saturday, July 10, 1982, at the Milton Fairgrounds, Milton, Ontario. Admission is $3.00 per person or $2.00 for pre-registration. There will be a flea market, displays, an auction, contests, and prizes. Camping will be available and grounds will open Friday night for early campers. For pre-registration, contact Mike Cobb VE3MWR, PO Box 836, Burlington L7R 3Y7, Canada.

BOISSEVAIN MAN CAN
JUL 10-11

The 19th annual International Hamfest will be held on July 10-11, 1982, on the Canadian side of the International Peace Gardens between Dunseith ND and Boissevain MAN in the Canadian Pavilion. Activities will include transmitter hunts, mobile judging, CW and OLF contests, seminars for OMs and YLs, flea markets, a ham auction, a Saturday night dance, a Sunday morning breakfast, and lots of great prizes. For more information, contact Bernie Arcand WD0MD, PO Box 53, Epping ND 58843, or William M. Shryock, Jr. WD0GRC, 322 East 4th Street, Williston ND 58801.

RAPID CITY SD
JUL 10-11

The Black Hills ARC will hold the annual South Dakota Hamfest on July 10-11, 1982, at the Surbeck Center, SD School of Mines and Technology, Rapid City SD. Pre-registration is $7.00; registration at the door is $8.00. There will be a prize drawing for pre-registrants, forums, contests, a picnic, and prizes. Tables are free for the flea market. Talk-in on .34/.94 (W0BLK). For further information, write Black Hills ARC, c/o Rudy WB0PWA, 4822 Capitol, Rapid City SD 57701.

MAPLE RIDGE BC CAN
JUL 10-11

The Maple Ridge ARC will hold its Hamfest '82 on July 10-11, 1982, at the Maple Ridge Fairgrounds, located 30 miles east of Vancouver, Maple Ridge BC. Registration for hams is $5.00; for non-hams over 12 years old, $2.00. There will be food, prizes, a swap & shop, displays, a bunny hunt, ladies' and children's programs, and a main prize drawing for a Kenwood TR-2500. Camper spaces will be available (some with electrical hookups). Talk-in on 146.20/.80. For more information and registration, contact Maple Ridge ARC, Box 292, Maple Ridge BC V2X 7G2.

ALEXANDER NY
JUL 11

The Genesee Radio Amateurs, Inc., will hold the second annual ARRL-approved Batavia Hamfest on Sunday, July 11, 1982, from 7:00 am to 5:00 pm at the Alexander Firemen's Grounds, Rte. 98 (nine miles south of Batavia), Alexander NY. Registration is $2.00 in advance, $3.00 at the gate, and $1.00 for the flea market. There will be many prizes, a large exhibit area, OM and YL programs, contests, plenty of food, overnight camping, and a boat anchor auction at 3:00 pm. Talk-in on 4.71/5.31 (W2RCX) or .52. For advance tickets, make checks payable to Batavia Hamfest, c/o Gram, Inc., Box 572, Batavia NY 14020.

MCKEESPORT PA
JUL 11

The Two Rivers Amateur Radio Club, Inc., will hold its annual hamfest on July 11, 1982, from 9:00 am to 5:00 pm, at the McKeesport Campus of Penn State University, McKeesport PA. There will be forums, prizes, food, an outdoor flea market, and indoor setups. Talk-in on 146.22/.82. For more information, telephone (412)-464-0550.

INDIANAPOLIS IN
JULY 11

The Indiana State Amateur Radio Convention, in conjunction with the Indianapolis Hamfest and Computer Show, will be held on Sunday, July 11, 1982, at the Marion County Fairgrounds at the southeastern intersection of I-74 and I-465. Gate tickets are $4.00 and entitle you to all activities, including the major prize drawing and hourly prizes. There will be inside and outside flea markets, a separate computer show and flea market, a commercial vendors' display area, technical forums, club activities, and ladies' programs. There will be setups after 12:00 noon on Saturday, July 10th. Security will be provided Saturday night and Sunday, and camper hookup facilities will be available on the grounds. For further information, contact Indianapolis Hamfest, Box 11086, Indianapolis IN 46201.

MANCHESTER NH
JUL 17

The New Hampshire FM Association will hold an electronics flea market on Saturday, July 17, 1982, at the Manchester Municipal Airport, Manchester NH, beginning at 9:00 am. General admission is $1.00 per person; sellers, $5.00. Sellers should tailgate or bring their own tables. Commercial displays are welcome. Refreshments will be available and door prizes will be awarded. Talk-in on 146.52 FM and 124.9 AM. For further information, contact Dick DesRosiers W1KGZ at (603)-668-8880, or Doug Aiken K1WPM, 30 Meadowglen Drive, Manchester NH 03103, (603)-622-0831.

SHEBOYGAN WI
JUL 17

The third annual Sheboygan County Amateur Radio Club Lakeshore Swapfest and Brat Fry will be held on July 17, 1982, from 8:00 am to 4:00 pm, at the Wilson Town Hall, south of Sheboygan WI. There will be a public auction and prizes. Tables are free and camping will be available at Terry Andre State Park. For a flyer and additional information, write PO Box 895, Sheboygan WI 53081, or call (414)-457-3203.

HARBOR SPRINGS MI
JUL 17

The Straits Area Amateur Radio Club will hold its annual hamfest on July 17, 1982, from 9:00 am to 4:00 pm at the Harbor Springs High School, Harbor Springs MI. Donations are $2.00 at the door and table space is $2.50. Doors will be open at 8:00 am for setups. Lunch will be served from 11:00 am to 1:00 pm and refreshments will be available during the day. There will be one main door prize and smaller prizes will be awarded hourly. The school parking lot is free for self-contained RVs to use for an overnight stay and many places of interest to YLs are available nearby. Talk-in on .52/.52 and 146.07/.67. For more details, contact Mr. Bernie Slotnick KB8RE, 630 Ann Street, Harbor Springs MI 49740, or call (816)-526-5614.

EUGENE OR
JUL 17-18

The Lane County Ham Fair will be held on July 17-18, 1982, at the Oregon National Guard Armory, 2515 Centennial, Eugene OR. Tickets are $4.00 each and entitle the holder to one extra drawing ticket free if purchased before July 1st. Doors will open at 8:00 am Saturday and Sunday. Features will include a swap and shop at $5.00 a table, a 2-meter bunny hunt, women's activities, a children's corner, computer demos, technical seminars, QCWA, and a grand prize of an Icom 730 low-band mobile rig. There will be an all-day snack bar, free parking for RVs (no hookups), and a Saturday potluck supper at 6:00 pm. Talk-in on .52/.52, 146.28/.88, 147.86/.26, and 3.910 HF. For advance tickets, send an SASE to Eunice Brown WA7MOK, 2456 Corral Court, Springfield OR 97477, or phone (503)-747-7939.

BOWLING GREEN OH
JUL 18

The 17th annual Wood County Ham-A-Rama will be held on Sunday, July 18, 1982, at the Wood County Fairgrounds, Bowling Green OH. Gates will open at 10 am, with free admission and parking. There will be drawings for prizes; tickets are $1.50 in advance and $2.00 at the gate. Trunk sales space and food will be available. Advance table rentals are $3.00 to dealers only. Saturday setup available until 8:00 pm. K8TIH talk-in on .52. For more info or dealer rentals, send an SASE to Wood County ARC, c/o S. Irons, PO Box 73, Luckey OH 43443.

WASHINGTON MO
JUL 18

The Zero Beaters Amateur Radio Club will hold its hamfest on Sunday, July 18, 1982, at the Washington Fairgrounds, Washington MO. Talk-in on 147.84/.24. For more information, contact Rich Noelke WA0NUI, Rte. 3, 10 Richard Drive, Washington MO 63090.

CANTON OH
JUL 18

The Tusco Radio Club (W8ZX) and the Canton Amateur Radio Club (W8AL) will hold the 8th annual Hall of Fame Hamfest on July 18, 1982, at the Nimishillen Grange, 6461 Easton Street, Louisville OH. Admission is $2.50 in advance, $3.00 at the gate, and children under 16 will be admitted free. The flea market will open at 9:00 am and activities will include awards, forums, dealers, and XYL programs. Talk-in on 146.19/.79, 146.52/.52, and 147.72/.12. For reservations and/or information, contact Butch Lebold WA8SHP, 10877 Hazelview Avenue, Alliance OH 44601, or phone (216)-821-8794.

LA PORTE IN
JUL 18

The LaPorte County Summer Hamfest will be held on Sunday, July 18, 1982, at the County Fairgrounds, LaPorte IN. Good food, cold drinks, and an indoor selling area will be available. For reservations and more information, write PO Box 30, LaPorte IN 46350.

GRAND RAPIDS MN
JUL 18

The Range Wide Hamfest will be held on July 18, 1982, from 10:00 am to 4:00 pm at Gunn Park, Highway 38, 6 miles north of Grand Rapids MN. Admission and tables are free. Bring the family for a picnic, games, prizes, and fun. Parking and campgrounds will be available. Talk-in on 146.28/.88 and .52. For more information, write Bob WD0AAF, 736 Crystal Springs Road, Grand Rapids MN 55744, or call (218)-326-2268 (evenings).

OKANOGAN WA
JUL 24-25

The Okanogan Valley International Hamfest will be held July 24-25, 1982, at the Okanogan County Fairgrounds, Okanogan WA. Registration is $3.00 for hams and $2.00 for non-hams. Activities will include bingo, a cake walk, a 2-meter bunny hunt, and a Sunday potluck dinner, followed by a drawing for prizes. Talk-in on 146.97. Hookups will be available for those who need them, and motels and restaurants are close by. For more information, contact Frank Bigelow WA7ZEV or Buck Buchanon W7GSN.

OKLAHOMA CITY OK
JUL 23-25

The Central Oklahoma Radio Amateurs, Inc. will hold the Oklahoma State ARRL Convention at "Ham Holiday '82" on July 23-25, 1982, at the Myriad Convention Center, Oklahoma City OK. Pre-registration is $6.00 and includes free flea-market tables. The pre-registration award is a Radio

Shack TRS-80 color computer. Featured will be a computer fair with programs on personal computers, plus an ARRL forum, AMSAT, DX and the Art of QSLing, FM, Antennas, and Alternate Energy Sources. There will be an indoor flea market, commercial displays, a ladies' program, and on Saturday night, July 24th, the Oklahoma Diamond Jubilee Banquet followed by a western dance. The Ham Holiday Grand Award will be presented on Sunday, July 25th. For registration forms and additional information, write CORA Ham Holiday '82, PO Box 15013, Del City OK 73155.

WELLINGTON OH
JUL 24

The Northern Ohio Amateur Radio Society will hold its annual ARRL NOARSfest on Saturday, July 24, 1982, at the Lorain County Fairgrounds, 18 miles south of Lorain, one mile west of Route 58 on Route 18, Wellington OH. Admission tickets are $2.50 in advance, $3.00 at the gate, and are good for all prize drawings. Children under 12 will be admitted free. Admission tickets may be ordered from NOARSfest, PO Box 354, Lorain OH 44052. There will be over 100 prizes, including an Icom 730 and power supply, an Ameritron, Inc., A1-80 linear amplifier, and an Icom IC-2AT. Featured will be a large flea market with parking spaces at $1.00 each, free parking, an indoor exhibit hall, refreshments, and free overnight camping (without hookups) on Friday. Indoor exhibit spaces with 8-foot tables are available at $8.00 each. Send a check for advance registration to Ernie or Pat Jackson, 201 Park Avenue, Elyria OH 44035. Talk-in on 146.52/.52 and 146.10/.70.

POUGHKEEPSIE NY
JUL 24

The Mt. Beacon Amateur Radio Club will hold its annual hamfest on July 24, 1982, beginning at 8:00 am, at the Arlington Senior High School, Poughkeepsie NY. Admission is $2.00 (XYLs and children admitted free), tailgating space is $3.00 (includes 1 free admission), and a table space is $4.00 (includes 1 free table and admission). There will be the free flea market tables indoors, parking door prizes, an auction starting at 2:00 pm, and hot food and beverages. Talk-in on 146.37/.97 and 146.52. For additional information, advance tickets, or registration, send an SASE to Walt Cotter WA2ZCN, North Hillside Lake Road, Wappingers Falls NY 12590, or phone (914)-226-6636.

GREENVILLE OH
JUL 24-25

The Treaty City Amateur Radio Association will be operating special event station W8UMD from the site of the Annie Oakley Days celebration, from 1600Z July 24 until 1600Z July 25. They will operate up 10 kHz from the bottom of the General band on 40 and 20 meters and will venture into the 40-meter Novice band occasionally. Send a business size SASE and QSL cards for a special certificate to TCARA, Box 91, Greenville OH 45331.

WEST FRIENDSHIP MD
JUL 25

The Baltimore Radio Amateur Television Society (BRATS) will hold its annual BRATS Maryland Hamfest on Sunday, July 25, 1982, at the Howard County Fairgrounds, Route 144 at Route 32, adjacent to Interstate 70, about 15 miles west of Baltimore, in West Friendship MD. Indoor tables with ac power are $15.00 each; without ac power, $10.00 each. Indoor tailgating is $5.00 per space; outdoor tailgating is $3.00 per space. Overnight RV hookups will be available. For more information and reservations, write to BRATS, PO Box 5915, Baltimore MD 21208.

CENTREVILLE MI
JUL 25

The Amateur Radio Public Service Association of St. Joseph County MI will hold its 4th annual swap and shop on July 25, 1982, at the St. Joseph County Fairgrounds, Centreville MI. Doors open at 8:00 am. Tickets are $2.00 in advance and $3.00 at the gate. Indoor tables are $2.00. Trunk sales are free. Camping is available Saturday night only for $6.00. Talk-in on 146.52. For more information, contact Dennis Cutler N8DDU, 3051 Z Avenue, Vickesburg MI 49097.

WHEELING WV
JUL 25

The Triple States Radio Amateur Club will hold its 4th annual hamfest on Sunday, July 25, 1982, from 9:00 am to 4:00 pm, at Wheeling Park, Wheeling WV. Admission is $2.00 (50/50); children under 12 will be admitted free. There will be major prizes plus door prizes every 15 minutes; a 15-minute auction every hour on the hour; free parking for 1,000 cars; refreshments; ARRL/SWOT/TSRAC booths; indoor dealer displays; and a flea market. There will be setups the night before or at 7:00 am Sunday morning. Talk-in on 146.31/.91 and 146.52. For advance dealer registration, electrical outlet and table requests, submission of free ads for the club's hamfest issue, and more information, contact TSRAC, Box 240, RD 2, Adena OH 43901.

NEW ORLEANS LA
JUL 25

The Delgado Community College Amateur Radio Club will hold its annual swapfest on Sunday, July 25, 1982, from 8:00 am to 4:00 pm, at the Peristyle in City Park, New Orleans LA. There is no charge for setting up, but those participating must bring their own tables. Admission is free. There will be plenty of free parking, and food and drinks will be available nearby. Talk-in on 146.67. For further information, contact Jim Wolfe, Club President, Delgado Amateur Radio Club, Delgado Community College, 615

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

I somehow find it hard to believe, but this column marks the beginning of the sixth year of RTTY Loop! Back in 1977, when I started this column in a local club newsletter, the most exotic item I was asked about was the Teletype® Model 28, or occasionally the Model 33. Now, in just a half-dozen years, the bulk of the questions concern adapting any of the myriad of personal computers to RTTY.

Many readers, having sensed my affection for the Motorola 6800 series of computers, have asked about programs directed towards that line. In the past, I have featured quite a few individual programs which allow receiving or transmitting RTTY on a 6800 system. One feature often requested, and certainly available on many commercial RTTY terminals, is the so-called "split-screen" capability. This is the display of both the received signal and transmit buffer on the screen at the same time.

Let's take a look at what such a program requires, and over the next few sessions see if we can develop a reasonable technique for implementing a split-screen RTTY terminal. In doing this, I will try to keep within my design philosophy, which is: If it can be done in software, do it. While this sometimes increases the complexity of the written code, I believe that in the long run working out a logical software solution to problems provides both a straightforward method of problem-solving and a cost-effective approach for the ham on a budget.

The first step will be to define what this terminal will need to do. Let's require only the ability to handle 60-wpm Murray (Baudot) code; other speeds will not be hard to add, and a given code set will keep things simple for the time being. I would like the top half of the screen to display the received signal, with the most recent lines being maintained, and the bottom half to show the transmit buffer. You should be able to fill the transmit buffer while receiving and continue to add to it even while transmitting.

I am going to have to be rather specific on the hardware requirements. We will be writing for a Motorola 6800-based computer, with the I/O block located at $8000, using the old "SWTPC" standards. A video-mapped display will be a must. Users of "smart" terminals, such as the Soroco IQ-120, can position the cursor anywhere using escape sequences, and this could be used to implement a split-screen display. However, in order to selectively scroll the screen, manipulation of data will be required directly, and this will necessitate the type of access a video board allows. While I will be writing for a GIMIX board, the program should be general enough to allow any of the popular video displays to work.

Now, on to the program. In the past, I have received some letters critical of my rapid entry into source codes. It seems that all of you are not as comfortable as I in the realm of LDAA and CPX instructions. I therefore shall wade in from the shallow end, although I prefer diving right in. Let's start by looking at the logic involved for this program.

Well, not just yet. You see, that's been another criticism. Flowcharts, those indispensable tools of the computer programmer, are just so much gobbledygook to a good number of you. I have, in the past, presented several flowcharts without much in the way of background. I shall attempt to rectify this omission herewith.

A flowchart is a map, diagram, or skeleton of a computer program, depending on how you look at it. Let's take a rather simple example. I say something like, "Take a number and call it A. Is it greater than 10? If so, print an H. If not, print an L. Now do it again." This sequence defines a logic sequence. Many of you familiar with BASIC, the rather universal higher-level language used in personal computers, could write rather rapidly from this description the program shown in Fig. 1. This would be one way to accomplish the task. Another is shown in Fig. 2, which is a 6800 assembly-language implementation of the same simple-minded job. I think you can see that there is quite a difference, and can imagine further differences when the process is extended to 6502-, 8080-, Z-80-, Pascal-, FORTRAN-, or APL-speaking computers. What is needed is some universal way to represent the logic sequence. That is the flowchart.

Steps in a flowchart are represented by boxes, each of which contains one logical process. This process may be a simple one-byte instruction or an entire subroutine. It doesn't matter, so long as it can be visualized as a unit. Different shaped boxes are frequently used to represent different types of processes. Three of those are shown in Fig. 3, with their definitions. There are many others, but these three will suffice for this month's flowchart.

```
0010 INPUT "TYPE A NUMBER",A
0020 IF A>10 GOTO 50
0030 PRINT "L"
0040 GOTO 10
0050 PRINT "H"
0060 GOTO 10
```

Fig. 1.

```
START JSR  INPUT
      CMPA 10
      BGT  HIGH
      LDAA 'L
      JSR  OUTPUT
      BRA  START
HIGH  LDAA 'H
      JSR  OUTPUT
      BRA  START
```

Fig. 2.

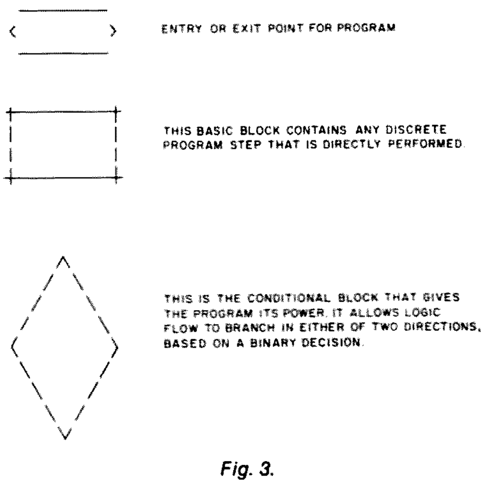

Fig. 3.

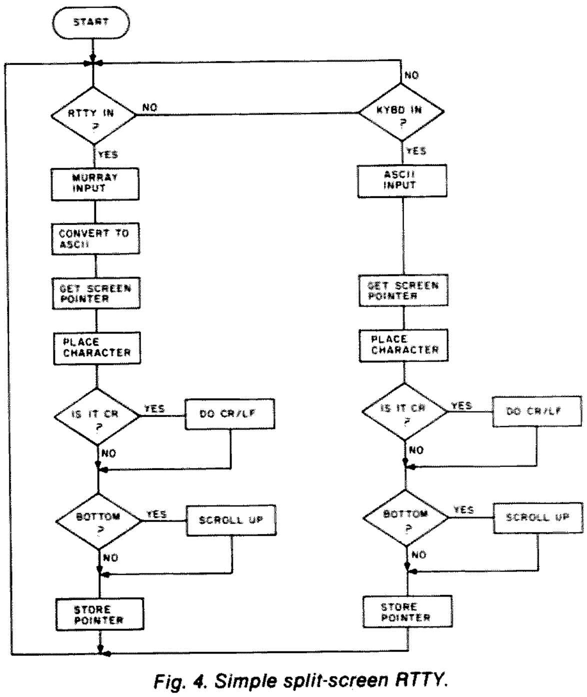

Fig. 4. Simple split-screen RTTY.

The boxes are connected by lines, through which logic flow is presumed to flow in a top-to-bottom, right-to-left direction. If flow is contrary to these directions, arrows are used to define such progression.

With this under our belts, let's take a look at the flowchart in Fig. 4. Entering at START, we immediately come to a decision. If there is a bit on the RTTY input pin, then a character is about to come in. If not, the local keyboard can be checked for input. If no data is found there, the program returns to check the RTTY once again and the loop continues.

If a character has been typed on the local keyboard, it is inserted into a buffer and displayed on the lower half of the screen. Later on, we will add some checking for special characters which will control the program or other features. For now, let's just be happy to fill the buffer.

Received RTTY characters are also stuffed onto the screen, but on the top half. During receipt of the RTTY character, however, there is quite a bit of time when the computer would be idling, waiting for these long, 21-ms pauses to go by. During these pauses, as shown in Fig. 5, the keyboard is checked once again. Input is allowed here, too, and again placed on the screen and stuffed into the buffer.

All this inputting and buffering requires a raft of pointers and protocols. Placing a character on the screen will require pulling a set of pointers from storage, placing the character on the screen, updating the pointers, checking to see if a new line must be started, and possibly scrolling that segment of the display. And all this must be accomplished within the wink of an eye.

Now that we have the road map, let's begin our journey. The program we will use is an implementation of an output routine which will serve as the window into the RTTY terminal we will be building. Before I go into the ins and outs of the program itself, maybe I'd better explain some of the rather peculiar GIMIX system function calls.

Like most operating systems, the GMXBUG monitor features a variety of routines which may be used to input or output characters or manipulate data in various ways. Unlike most, which use subroutine calls to access such routines (JSR ADDR or $BD $nnnn), GMXBUG provides for the use of the software interrupt (SWI or $3F) instruction to create a set of two-byte pseudocodes. In the typical sense, one may write the code $3F $10 to input a character, for example, rather than the MIKBUG style $BD $E1AC (JSR INEEE).

Moreover, GMXBUG features several routines not offered in other 6800 monitors, many of which demonstrate a high level of utility. While these routines may be written in for systems based on another monitor, as long as they are here, why not use them? In order to allow the assembler to handle these two-byte pseudocodes, I write them as double-byte data statements (FDB) and call them as such.

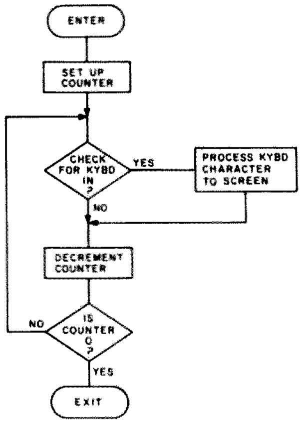

Fig. 5. Murray input delay routine.

Fig. 6.

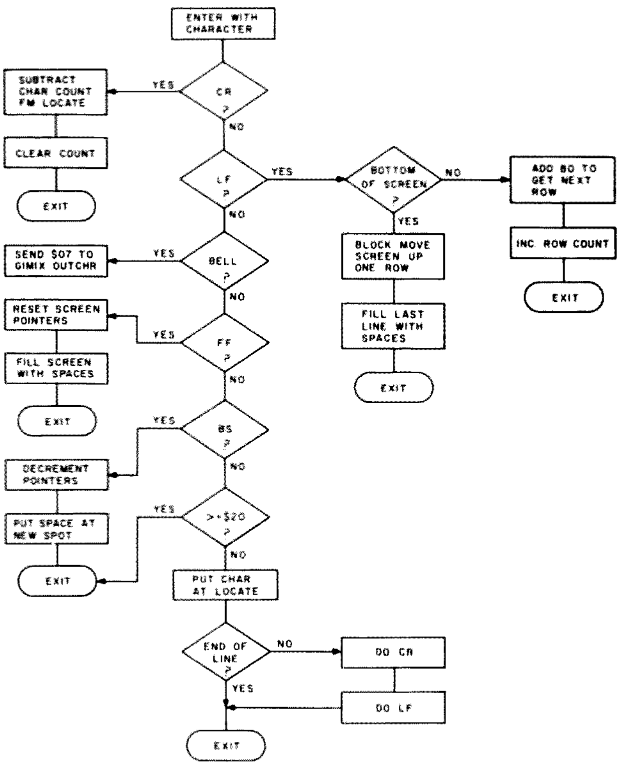

Fig. 7.

Routines used in this month's program include:

ADDAX ($3F04)—Adds the contents of accumulator A to the contents of the index register and places the result in the index register. The addition is unsigned. The former contents of the index register are lost.

SUBAC ($3F06)—Subtracts the contents of accumulator A from the contents of the index register and places the result in the index register. The subtraction is unsigned. The former contents of the Index register are lost.

MOVER ($3FOE)—A general purpose block-mover routine. Moves the contents of memory starting at the address in BEGIN1 ($A002) through the address in END1 ($A004) inclusive to memory starting at the address in BEGIN2 ($A014). Checks for overlap of source and destination areas. If necessary, the move Is done back-to-front.

OUTCHR ($3F11)—Conventional character output to the video-driver routines of the ASCII character contained in the A accumulator.

Enough background? OK, let's see how we can chop a screen in half. The listing in Fig. 6 is a demonstration program to do this. The flowchart in Fig. 7 can be followed step by step, to see how the listing was developed.

To begin with, we shall recognize that certain non-printing characters are useful, so let's screen for them. A carriage return, line feed, bell, form feed, and backspace, each in turn is checked for. Should any of them be found, a branch to a corresponding routine is done, and we will cover those later. Any other control character we will ignore for now.

The handling of printing characters is straightforward. The address of the next character to be printed is stored at a spot we will call "LOCATE." So, we get that address, place the character there, increment to the next spot, and store it. Now, a line counter, call It "COUNT," is incremented to see where on the line we are. If at the end, calls to the carriage-return and line-feed routines initiate a new line. Which routines are these? Why, the same routines that a carriage return and line feed call up, no? Yes! And I bet you thought this was going to be complicated.

Now let's take a look at some of those special routines. What's that I hear? OK, carriage return, you first. What is a carriage return after all? A resetting to zero on the current line, that's all. So, to implement a carriage return, first we load the current location into the index register, then the character count (where on the line are we?) into the A accumulator. Subtract the two, using that SUBAX routine, and you have the beginning of the line. Store that as the new location, clear the line count itself, and the carriage return is done.

Line feed? No, let me save you for last. How about something easy, like the bell. This nonprinting character rings a software bell in the GIMIX system. So let's just send it out through the regular character output. Well, so much for that one.

The form feed is used to clear the screen, and it is a neat character; let's see why. First, we set the character location to the first one in the screen sector, clear the character count and set the row counter to the first row. Next a loop is entered to load the entire screen window with spaces ($20). When that's done, the screen is reset and clear.

Backspace is also not so hard. For now, let's prohibit backspacing past the beginning of the line up onto the previous line. So, we check the character counter and If it's zero we don't backspace. If it's OK, just decrement the count, store it, decrement the location, store it, and put a space where we are now. Like I said, not so hard.

OK gang, time to roll up our sleeves and look at the line feed. If we take it one step at a time, it shouldn't be too hard. We have been keeping track of current row on the screen, as well as character position on the line. So first we must check the row counter and, if the current row is the last on the screen, initiate a scroll. Hang onto that one for a second. If not a scroll, it is easy. With eighty characters per line, adding eighty to the current location gives the corresponding spot on the line below. Increment the row number, add eighty to the location, store all this new data, and we are done.

Now, about that scroll, let's look. First, we find the start of the second screen line; this will become the top line after the scroll. This address is stored in BEGIN1 for use by the MOVER routine. The end of the screen defines END1, and the data on display is shifted up one line. Now one more task needs to be taken care of. The last line on the screen is filled with spaces, clearing it for new data.

Note, by the way, that the carriage return does not initiate a scroll, nor does a line feed reset position within a line. It takes both!

The data and storage needed for the program is situated at the end of the instructions. I've got to indicate here that there is nothing sacred about using the bottom thirteen lines, as shown here, or the whole eighty characters across. Change it to the middle sixteen lines with thirty-two characters if you are nostalgic. Versions of this same routine will be used for several windows in the RTTY terminal which we will be building up.

As time goes on, we will continue to develop the routines needed, one by one, for this full-featured RTTY terminal. Next month, though, I'll take a crack at some of the mail from readers which has been piling up on my desk. That and more, In RTTY Loop to come.

HAM HELP

I need manuals and/or schematics for the following:

- SG92 A/U rf sweep generator
- Nems Clarke receiver 2501B
- Nems Clarke signal display SDU 350-9
- Nems Clarke Range Extender REU 300B
- Tektronix Model 564 (early model) oscilloscope mainframe

I will pay reasonable costs for copying and postage.

TVRO: Georgia Style

—one man's junk is another man's antenna

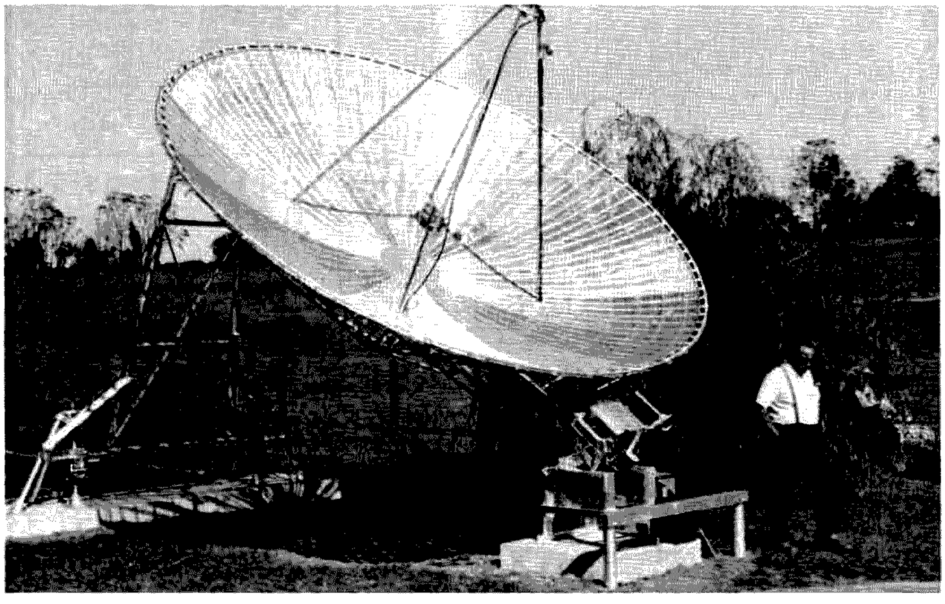
Timothy Daniel N8RK
73 Magazine Staff

This is not the typical *73* construction article. Herman "Tex" Friedsam's satellite TV antenna is not offered in kit form, nor are a complete set of plans available.

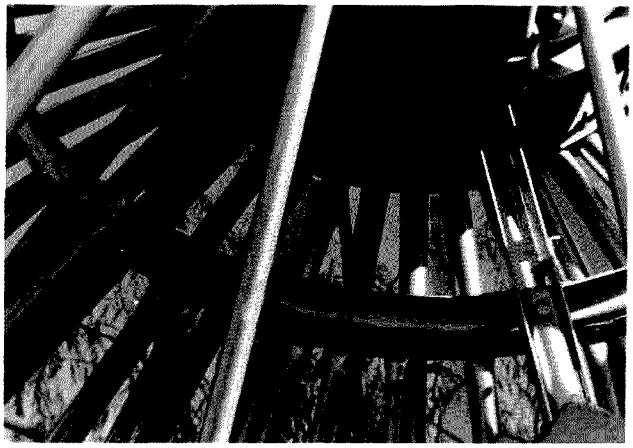
Just in case you still want to give this project a try, here are some of the parts you will need: the magnesium bell housing for a helicopter's propeller, one line shaft from a cotton gin, and don't forget the swivel-type hitch from a cultivator. With those items acquired, it is time to continue the search, this time looking for a worm gear reducer (Tex salvaged his from a brick factory's conveyor); you'll also need a frame for the drive mechanism—try the local hammer mill.

What may sound like a hopelessly incompatible pile of junk has become an engineering masterpiece in the small town of Marshallville, Georgia. Tex, whose ham call is WA4OPY, approached this project like he does most things. Using his experience as a textile plant engineer, he started with an idea but not a plan. After collecting several of the key components, he settled on a design for a 15.27888-foot-diameter parabolic reflector. The 18 hours of research and planning were among the project's easiest work. Construction of the frame, which began in the spring of 1979, took almost 200 hours. Realizing that painstaking accuracy results in a better picture when you are done, Tex and a friend each spent 12 hours making a plywood template of the antenna's curved surface. Two thousand feet of electrical conduit and PVC pipe later, the frame was ready to cover with aluminum screen. The basic dish, when completed, weighed only 425 pounds.

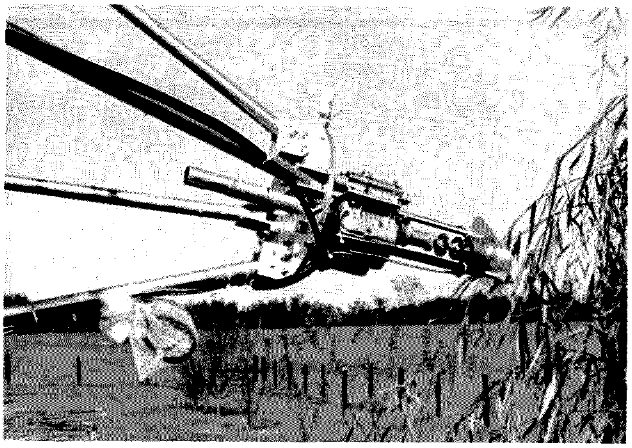
Tex's research pointed out the imperfections of the polar mount, the traditional way a dish scans the hori-



Tex WA4OPY with his home-brew dish.



The antenna's hub is constructed around a helicopter's propeller bell housing. An octagonal frame, eight feet in diameter, extends outward, supporting the antenna's surface.



The feed assembly allows the horn polarization to be changed via a TV rotor and there is provision for very fine adjustments of the horn location. This allows the receive signal to be maximized.

zon. By building a frame that could be moved horizontally as well as in a polar arc, the WA4OPY antenna can be accurately positioned with a minimum of fudging. The major supporting axis is the only part of the system fabricated by an outsider. A 1/2-horsepower motor used to turn the dish is the only component that was purchased new. The rest of the parts were salvaged from local scrap piles. Being the owner of a hardware and variety store didn't hurt, nor did Tex mind using "scrap" from his brother-in-law's grain mill.

Patience seems to be the main rule behind this project. When it came time to fine-tune the antenna's surface, Tex spent 61 hours, much of it with a flashlight and a piece of shiny aluminum. When he was finished, the dish's focal point was no bigger than a nickel. As Tex got around to building a feed assembly, he decided that there was nothing suitable on the commercial market, so he designed his own. It worked so well that he has started to manufacture them for other hobbyists.

By April of 1981, almost two years after he started construction, Tex was ready to give his system a try. The electronics, like the antenna, were home-built. The first pictures, in Tex's words, were "lousy images of a Snoopy cartoon." Today, "lousy" pictures have been replaced by clear reception and satellite television has become part of the Friedsam family life. The receiver has been built into an attractive piece of living room furniture and the dish, which sits across the driveway, moves somewhat mysteriously by remote control.

Tex carefully documented the construction of his system, keeping track of the materials and time he used. For instance, 1700 3/8-inch sheet-metal screws were needed to apply the aluminum screening, and it took 29 hours to install a shielded underground cable between the house and the dish.

Along the way there were many sources of frustration; for example, the frame broke when it was ninety percent complete. Tuning up the microwave circuitry required a signal generator that none of the local scrap piles could offer. Tex built his own, using a klystron tube.

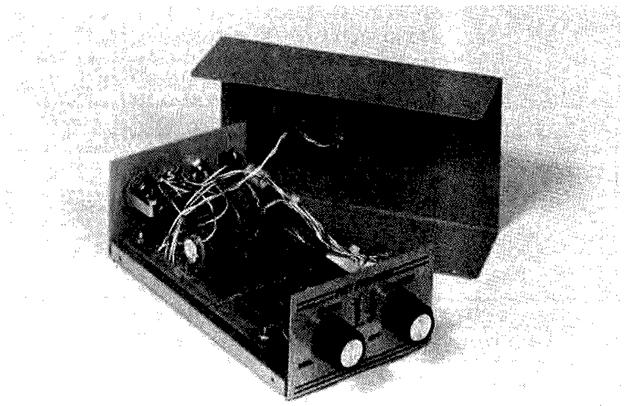
Perhaps the most impressive fact concerning Tex's accomplishment was that he had never seen a TVRO installation and he had never been within a mile of a large parabolic antenna. Working from theory and the scrap piles of Marshallville, Georgia, he has built a functional monument to the home-brew spirit of radio. ■

The dish, which is almost 16 feet in diameter, has a frame built from PVC pipe and electrical conduit. The supporting bar, which spans the dish, is the only piece that Tex did not fabricate himself.

NEW PRODUCTS

STRAIGHT-KEY KEYER

Designed exclusively for straight-key users, the Fist Fighter is an electronic keyer that accurately times the length of dots, dashes, and the spaces between them. The Fist Fighter uses a standard 1:3:1 timing ratio and requires no new hand motions. An automatic tune-up feature is built in so that normal key-down tune-up is possible, without the need for any extra switches. Speed is variable from about 3 to 30 wpm. The Fist Fighter will key grid-block and solid-state transmitters/transceivers. It is available in two forms: kits cost $59.95 and an assembled version sells for $79.95. Additional information and specifications are available from *The Blacksburg Group, Box 242, Blacksburg VA 24060.* Reader Service number 482.

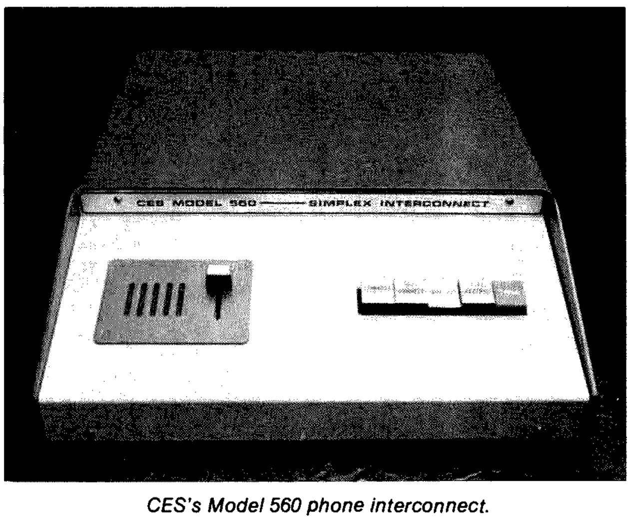


The Fist Fighter.

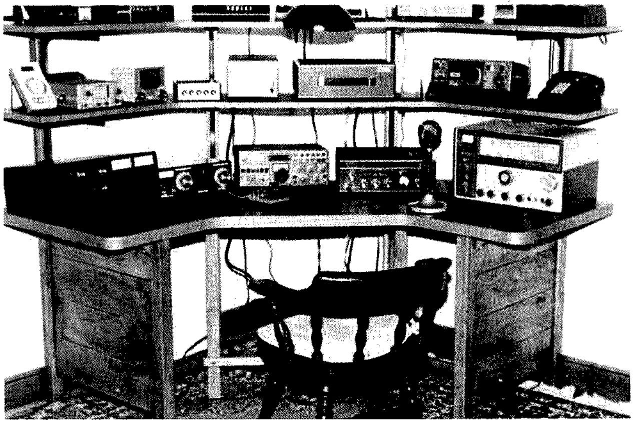
PHONE INTERCONNECT

The CES Model 560 interconnect is designed to interconnect a base station or control station to a telephone line. The 560 is a sampling type of interconnect, using no VOX circuits for control. The Model 560 is one way that repeaters located away from phone lines can have autopatch capability. When the interconnect is in use, the control station will transmit for one second and then sample the receiver for ten to twenty-five milliseconds to determine if a station is transmitting. If a signal is found, the control station will stay on receive until it stops; if no signal is present, the control station will transmit for another second.

Toll-restrict and dial-out capability can be enabled by front-panel switches. The Model 560 does not affect the use of the control station for normal communication. It is priced at $990. For more information, contact *Communications Electronics Specialties, Inc., PO Box 507, Winter Park FL 32790.* Reader Service number 478.



CES's Model 560 phone interconnect.



CQ Products' operating desk.

SHACK FURNITURE

CQ Products announces the introduction of an operator's desk designed like an organ console to place all the operator's equipment within easy view and reach. The desk surface and shelves are constructed of 200-pound industrial-grade chipboard and are covered with formica. The two shelves are adjustable in height to accommodate virtually any ham or computer gear.

The desk is designed to fit into the corner of your ham shack and is also attractive enough to be placed in your living room or den. The desk occupies 60 inches from the room corner to each edge. It is priced at $495. For more information, contact *CQ Products, 8280 Janes Avenue, Suite 137-1700, Woodridge IL 60517.* Reader Service number 476.

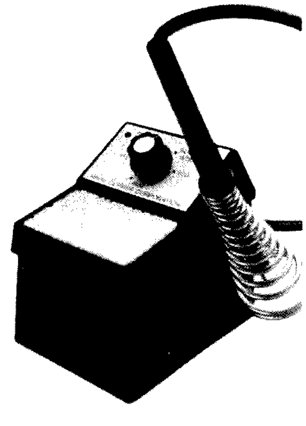
MICRO SOLDERING STATION

The Wahl Clipper Iso-Tip 7470 micro soldering station eliminates continuous switching to maintain temperature and, therefore, the spikes that can damage delicate electrical components. The totally grounded unit can be adjusted for any temperature between 500 and 700 degrees F. With the selection of the proper tip, heat is delivered only to those points where it is needed. The temperature-adjustable soldering station comes complete with sponge holder, tip-wiping sponge, soldering iron, and stand. The suggested price is $47.75. For further information, contact *Wahl Clipper Corp., PO Box 578, Sterling IL 61081.* Reader Service number 479.

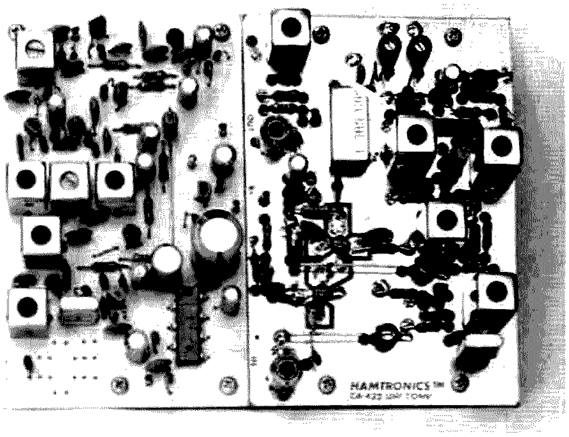
VHF KITS

The R76 VHF FM receiver kit is an improved version of the R75 receiver for 10m, 6m, 2m, 220 MHz, or the adjacent commercial bands. It features a very low-noise front end, pump-resistant squelch with hysteresis to lock onto fading signals, onboard volume and squelch controls for easy wiring, and fixed i-f filters for easy alignment. It is available in two selectivity options, starting at $84.95.

A new UHF receiver kit has also been introduced. The

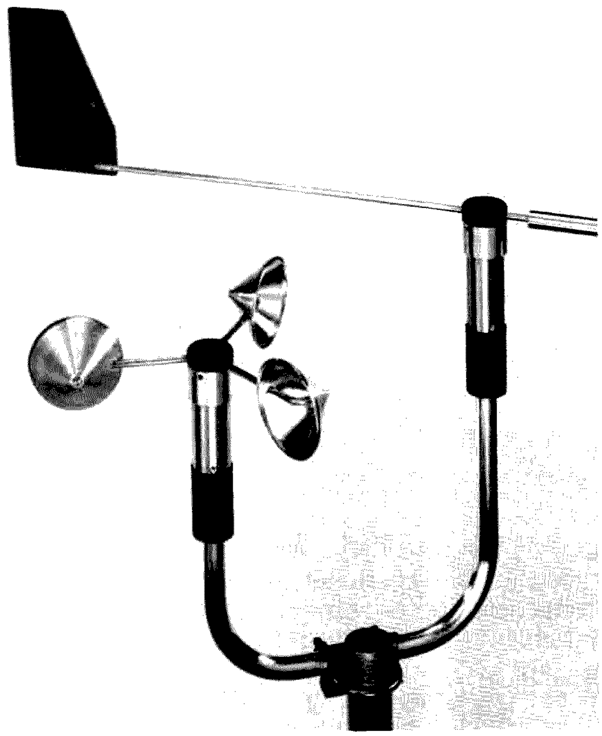


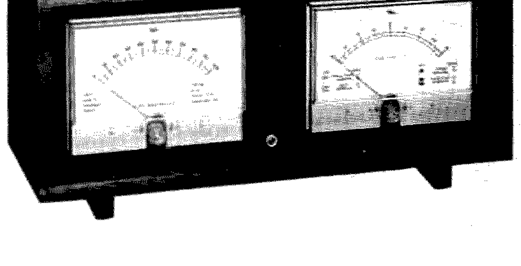
Wahl's Iso-Tip 7470 micro soldering station.



Hamtronics' Shuttle receiver.

Palomar Engineers' PT-407 antenna tuner.





TMAC Products' S.D.-500 weather station.

model R451 includes the features listed above plus automatic frequency control to lock onto drifting transmit signals. Kits are available with various options starting at $94.95.

Hamtronics has a new line of low-noise amplifiers. In appearance, they resemble Hamtronics' earlier P30 and P432 receiver preamplifiers, but the circuit is new. They are optimized for lowest noise figure in the ham bands but can also be used on adjacent commercial bands. Noise figures typically run 0.5 dB at 28 and 50 MHz, 0.6 dB at 144 MHz, 0.7 dB at 220 MHz, and 0.95 dB at 432 MHz. Gain runs from 33 dB at 28 and 50 MHz to 17 dB at 432 MHz.The price is $39.95 for the VHF units and $44.95 for the UHF unit, all wired and tested.

The Hamtronics R110-450 UHF AM aircraft receiver may be used to listen to the Space Shuttle. Good results have been reported using simple UHF antennas. The special Shuttle receiver kit is available off the shelf for $94.95.

For further information on these products, write to *Hamtronics, Inc., 65-V Moul Road, Hilton NY 14468; (716)-392-9430.* Reader Service number 480.

WEATHER STATION

TMAC Products is introducing the S.D.-500 weather station. This system provides wind velocity indications from 0-100 mph and wind direction readings covering 16 compass points. The console is constructed of hand-finished mahogany and the transmitter can be up to 300 feet away from the console and a 50-foot cable is supplied. The unit is powered by 155 volts ac. The list price is $360. For more information, contact *TMAC Products, PO Box 28341, Columbus OH 43228.* Reader Service number 483.

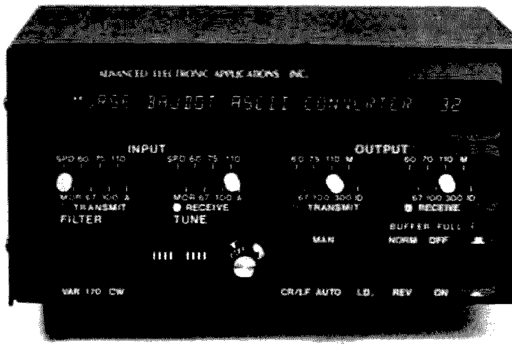
ANTENNA TUNER

The Palomar Engineers PT-407 is a general-purpose tuner for 1.8-30 MHz to match antennas fed with coaxial or open-wire lines, single-wire or mobile antennas. The 300-Watt power rating makes it just right for most transceivers. The PT-407 is an efficient tuner with a large airwound coil, a large balun for open-wire feed, and ceramic insulation throughout. It is housed in an 8" × 4" × 7" aluminum cabinet. All controls are on the front panel, coaxial connectors are S0-239, and porcelain insulators are used for balanced lines and single-wire inputs. The PT-407 antenna tuner sells for $149.95. For more information, write to *Palomar Engineers, 1924-F W. Mission Road, Escondido CA 92025.*

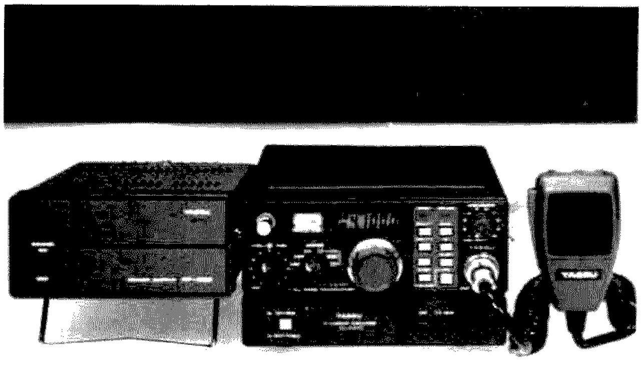
SATELLITE STATION

The Ten-Tec Model 2510 contains a 435-MHz USB/CW transmitter and a high dynamic range 2-meter-to-10-meter receive converter. The Model 2510 and a 10-meter SSB/CW receiver provide full duplex, transmit, and receive functions for operating on the upcoming OSCAR Phase 3 satellite in Mode B.

The transmitter operates from 435 to 435.5 MHz (coverage can be extended to 437 MHz with an optional oscillator). Ten Watts out is available in USB and CW. The receive portion converts 144-146 MHz to 28-30 MHz. A 12-volt power supply is required. Amateur net price for



AEA's MBA-RC reader/converter.



Yaesu's FT-290R transceiver.

the Model 2510 is $489. For more information, contact *Ten-Tec, Sevierville TN 37862.*

READER/CONVERTER

The Advanced Electronics Applications MBA-RC (Morse, Baudot, ASCII Reader/Code Converter) is actually several sophisticated devices all wrapped up in one package. The unit performs as a full-function decoder and display unit for Morse-, Baudot-, and ASCII-coded signals, operating directly from the audio output of any stable communications receiver. The MBA-RC also encompasses a Morse, Baudot, and ASCII encoder and code converter. The unit will perform serial-to-parallel and parallel-to-serial code conversions as well as cross-mode conversions. All the necessary analog processing and tone generation for two-way contacts in any MBA codes is included.

Other features include a built-in sidetone monitor, an FSK tone generator, and an automatic station ID message. The MBA-RC has a list price of $469.95. For more information, contact *Advanced Electronic Applications, PO Box 2160, Lynwood WA 98036.* Reader Service number 477.

PORTABLE TRANSCEIVERS

The FT-290R and FT-690R are multi-mode battery portable transceivers for 2 meters and 6 meters, respectively. Designed for 2.5 Watts output on SSB, CW, and FM (the FT-690R also has AM), these transceivers use liquid crystal displays and include scanning in variable steps. The FT-290R and FT-690R are powered by alkaline or nicad C-cells (not supplied). The FT-290R is priced at $399 and the FT-690R is offered for $379. For more information, contact *Yaesu Electronics Corp., PO Box 49, Paramount CA 90723.* Reader Service number 481.

Dealers . . . SELL

Selling *73 Magazine* will make money for you. Consider the facts:

Fact #1: Selling *73 Magazine* increases store traffic—our dealers tell us that *73 Magazine* is the hottest-selling amateur radio magazine on the newsstands.

Fact #2: There is a direct correlation between store traffic and sales—increase the number of people coming through your door and you'll increase sales.

Fact #3: Fact #1 + Fact #2 = INCREASED ALE, which means more money for you. And that's a fact.

For information on selling *73 Magazine*, call 800-343-0728 and speak with Ginnie Boudrieau, our bulk sales manager. Or write to her at *73 Magazine*, 80 Pine St., Peterborough, NH 03458.

73 MAGAZINE

RF **ANNOUNCING**

RF PRODUCTS announces production of 5/8 wavelength VHF telescoping antennas for 144-148 MHz (2M) 152-174 MHz and 220-225 MHz (1¼). These new antennas are intended for use on hand-held and base station transceivers. They are available with BNC connector, 5/16-32 stud or PL-259 connector. A telescoping brass nickel-plated nine section radiator is used for lighter weight and less RF junctions than previously available 5/8 wavelength antennas. Maximum gain is achieved by the combination of a base spring for whip protection and a tuned matching network for minimum VSWR. Minimum 2 meter bandwidth for 1.5:1 VSWR is 3.5 MHz. Overall length with BNC connector is 44¼ inches (110.25 CM). The BNC connector and 5/16-32 stud models are intended for hand-held transceiver (HTs) use and the PL-259 model which includes a type M359 right angle adaptor is intended for direct rear mounting on base station transceivers. Suggested list price for all models is $19.95, the most popular of which are listed below.

P/N	DESCRIPTION	P/N	DESCRIPTION

HAM HELP

I am looking for some ideas for simple FM detection in a military R-19 receiver. The unit tunes through the 2-meter band and operates from a 28-V-dc supply.

Dick Levy WB3EVY
1331 Hale St.
Philadelphia PA 19111

I am looking for a copy of the tube chart and updating information for the B & K Precision Model 650 tube tester. I will pay postage both ways so that I can photocopy it.

Larry Schuldt
545 Willow Rd.
Marengo IL 60152

I need instructions for rewiring a standard 6-button telephone keyset so that it can be used with a Western Electric (Ma Bell) 212A modem. I will pay reasonable copying costs and postage.

Doug Ranz N8CDX
PO Box 1425
Warren MI 48090

I have a Jackson Electrical oscilloscope. If I can borrow either the complete manual (instruction) or schematic for Xeroxing, I will return and pay all postage.

Peter Dal Corobbo
18650 Marshall Ave.
Homewood IL 60430

I am looking for manuals/schematics for the following:

- Midland 13-505 2-meter transceiver
- Cleaver Company Model 33A electronic keyer
- Boehme 5C frequency shift converter
- Acton Labs, Inc., Model #810 VTVM

I am also looking for any modifications to improve the Ten-Tec Argonaut 505 transceiver, especially for vfo stability and receiver sensitivity. I will gladly reimburse copying/mailing costs.

Gary Kohtala WA7NTF
S & F Co., USAISD, Box 918
Ft. Devens MA 01433

I would like to buy a National NCX-A ac power supply.

Gary Jones
PO Box 26313
Houston TX 77207

I need help in obtaining a replacement nicad pack for a Wilson Mark IV 4-Watt, 2-meter hand-held transceiver.

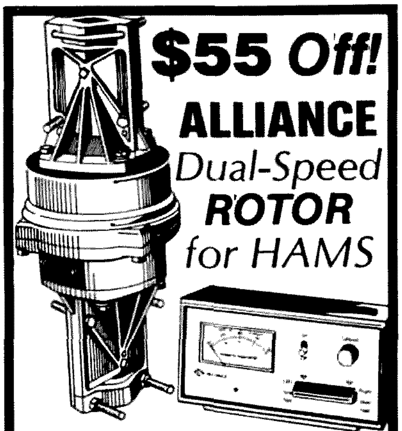
W.A. Lieseke WB7PUP
426 Bremerton Blvd.
Bremerton WA 98312

I need an operating manual/schematic for a Dumont Labs cathode-ray oscillograph, type #208. Costs paid.

Glenn Churchill KA2IOI
21 Bay St.
Glens Falls NY 12801

I would like to modify my Sony ICF-6800W to contain a noise blanker and to receive on longwave. I would like to locate some hardware or technical information concerning these modifications.

Mark Hunt
2135 South Union Ave.
Bakersfield CA 93307



$55 Off!
ALLIANCE Dual-Speed **ROTOR** for HAMS

ALLIANCE HD-73 *Dual-Speed* rotor for Medium sized Ham antennas. Strong aluminum construction with hardened-heavy pitch steel gears & 100 ball bearings. Rated for up to 10.7 ft² wind load area & 1000 lb vertical load. 450 in/lbs starting torque. Mounts in-tower, on tower or mast; accepts 1¼"-2½" O.D. mast. Rotates at (1) RPM for moving over a large arc or *slow* for peaking signals. Automatic brake system, large 3½" meter, calibrated S-W-N-E-S in 10° increments. Black case, brushed aluminum front panel & bezel. 17 lbs.

Regular $154⁹⁵ - ***Sale Price $99⁹⁵***

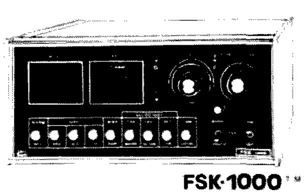
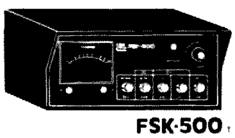
RTTY Demodulators



FSK-1000™

Here is no compromise design and construction:
- Unparalleled selectivity achieved with sophisticated limiterless design utilizing ultrasharp active filters and decision level correction circuits
- The most flexible interface system available to computers and high voltage loops
- Built in 170 volt loop supply
- Selectable bandwidths of 55 and 100 Hz. (copies 110 Baud ASCII)
- Continuously tunable shift coverage
- Rugged construction - commercial quality throughout
- Full complement of rear panel connectors for easy interface
- Keyboard activated switch for break in operation
- Individual tuning meters and LED's for quick, accurate tuning



FSK-500™

This RTTY demodulator is designed for computer interface but is a fine stand alone unit:
- Easy computer interface with RS-232 or 5 volt logic signals
- Three shift coverage without straddle tuning
- Selectable bandwidths give you optimal Baudot or 110 Baud ASCII copy
- Input bandpass preselector using active filters
- High voltage loop keyer output
- Autostart built in
- Three shift AFSK keyer plus narrow shift CW ID
- Fully wired and tested: ready to copy!
- The FSK-500 is the best demodulator available for under $500.00 (Except for our FSK-1000!)
- Positive tuning with meter and LED's

NEVER SAY DIE
editorial by Wayne Green

from page 8

found Haiti. The Bahamas are treacherous, so we were very lucky not to run onto any of the thousands of shoals and reefs.

Exhausted by the storm, we found a protected bay and anchored to rest. A couple of hours later, we awoke to find ourselves at gunpoint—faced by a bunch of excited Haitians who had sneaked aboard our ship. They spoke no English and no one in our group spoke any French... except me. I quickly started trying to remember what I could of my high school French, twenty years unused and mostly forgotten. The menacing guns prompted my memory.

It turned out that these were police from nearby Mole St. Nicholas. They were convinced that they had captured a bunch of invaders bent on taking over Haiti and were looking forward to a good deal of publicity and perhaps *rewards* from the government. The idea died hard, but I finally convinced them that we were a scientific team. How could I ever explain to these simple people that we were hams bent on visiting a deserted island to set up a radio station for *fun*?

We visited the town. Have you ever visited a place where the average income is about $50 per year? Some of our welfare customers should have a chance to see what real poverty can be!

From there we sailed across to Navassa and looked it over. Hmmm. Formidable. Just one place to get up the cliffs which completely surround the island ...and that via a wire rope ladder, with the waves shoving your boat into the undercut cliffs where it would be instantly shredded. We went back to Haiti to rent some Haitians and a small boat so we could get the ham gear onto the island.

At Cape Dame Marie, I once again managed to remember enough French to get the help we needed...and make the bargain. The head of the village made the bargain and gave us two Haitians and a boat. We found out later that he had no intention of giving the two chaps one cent of the pay. We towed the boat with the Haitians behind our ship back to Navassa. On the way one of them managed to fall overboard. Luck was with us and one of our group was looking that way when it happened so we were able to stop and circle around to pick him up. Damned fool couldn't swim and he was thrashing around, which attracts sharks. He wouldn't have lasted ten minutes.

With the help of the Haitians we got all of our ham gear from the boat to the top of the cliff. I'm afraid that *we* had to do most of the work. It was hot and dry. The damned island is covered with cactus and a wide variety of bushes with burrs. They seem to jump out at you if you even get close to them.

We set up two stations, one right at the top of the cliff and the other a couple hundred feet away. We had an enormous gas-driven power generator, two complete towers with beams, and rotors. We spared no expense to be well equipped. Our main receiver was a Drake 1A, a sideband (and CW) only receiver. That was a new way to go back in the early days of sideband.

The ship headed back to Haiti after leaving us off, scheduled to return for us in a few days... we hoped. Soon after the ship left, we found that we had a little problem. Oh, the rigs worked fine, but the heat was merciless and we found that our water supply was zilch. It turned out that the 50 gallons of water we'd brought had been in a rusty drum and had all leaked out on the trip down. Chet had noticed this and solved the problem by not bothering to bring the drum with us to the island. So we were faced with several days without water on this tropical desert island.

A couple of us explored the island, hoping to find some water. At the very top of the island was a tower with a beacon light. It was powered by acetylene which was piped up from bottles kept in a small shed near the tiny bay where we had our ham rigs. We found the remains of a house where, in earlier days, a lighthouse keeper had lived. Digging down through the remains of the house we found a cistern under the rubble. It had quite a bit of slimy water still left in it ...but water it was!

We brought the water down in cans and bottles and boiled it. After a day we got tired of the boiling procedure and decided to see if this was really necessary. Chet, who in many ways had managed to isolate himself from the rest of us, was chosen (without his knowledge) to be the guinea pig. We gave him the untreated water and waited to see if he would survive. He didn't seem to notice anything so we all switched to untreated water.

Navassa had not been active in many years so we had a ball on the air, knocking 'em off by the thousands. Talk about pileups!

When we were getting the equipment from the ship to the small boat and then from there up onto the island, some of the key beam antenna elements managed to slip out of the sling and fall into the water at the base of the cliff. I had my scuba tanks with me just in case of something like this, so I was elected to go after the lost aluminum.

It turned out that the water was only about 60 feet deep right there so I was able to surface dive and bring it all up. I can hold my breath for a minute or so and do pretty well in anything less than 75 feet without the scuba equipment...as long as it is just going down and then back up again. The many sharks and barracuda put the others off from much swimming. I tried to assure them that the fish were just curious and to ignore them, but I wasn't very convincing apparently.

Once the pileups ran down, we packed up and sailed back to Haiti where a couple of us left to fly home and back to business. Four of the group came back with the ham gear to Nassau. I eventually got back most of my ham gear, but never saw my two scuba tanks again.

I ran an article in *CQ* on the DXpedition, doctoring up the photo of the loading area and the cliff with a big "W2NSD" sign. This seemed better than the Coast Guard graffiti which was actually there. Later DXpeditions to Navassa brought paint planning to cover up my W2NSD with their calls. Not finding it, they painted their calls everywhere and made an awful mess.

I have a great 16mm color movie of the expedition which might be of interest some day. My slides were, unfortunately, out on loan to a ham club at the time I was fired from *CQ*, and I was *never able to get them* back.

In 1972, a group of hams from Atlanta decided to do a Navassa DXpedition trip and I got invited. The leader was Chaz Cone W4GKF, who also runs the yearly Atlanta Ham Festival and was recently involved with the new IBM microcomputer system.

This time we flew to Jamaica, where it was only an overnight boat trip to the island. Piece of cake.

The *Time* article was in error on a couple of minor points. The description of amateur radio as a burgeoning (to grow or develop rapidly) hobby is nice to read, but a bit optimistic. And I don't know how one makes mutton stew out of a goat. Goat stew, sure...and it can be delicious if you don't know the name of the goat involved.

They are right about one thing: DXpeditioning is exciting and fun. It *is* adventure and I guarantee that if you break loose and go on one, that you will never forget one single minute of the trip, no matter how long you live. There are not many adventures left like that in our protective (perhaps overprotective) world. Giving a few thousand hams a new country merely supports a branch of the hobby which is of questionable value—country chasing. Few hams in rare countries enjoy the pressures this forces on them, which leads to rare countries being even rarer...thwarting one of the basic values of amateur radio: international friendships.

Maybe we could set up a new rule which would *only* give country credit if you work a DXpedition.

CHINA!

Speaking of adventure...and keeping in mind the recent acti-

vation of China...perhaps you can take the time to break loose this fall and join me for a short trip to China. Ten of us went to Canton a little over a year ago and had an experience that none of us will ever forget.

This fall, starting in late October, there will be a tour of the electronics shows in Tokyo, Seoul, Taipei, and Hong Kong. From there we will go to Bejing for a couple of days and then on around to other electronics shows in Munich and London. Yep, this trip not only will get you into the most interesting places in Asia, including Peking, but is an around-the-world tour.

In general, the tour allows a couple of days for each electronics show and then one for travel, which means that the seven-city tour takes about three weeks. The cost is around $4,000 and that includes first-class hotels, all transportation, and perhaps more meals than you may be able to handle. Some of the meals on these tours are spectacular.

At the shows you get to see the latest in consumer electronic equipment, small computers, and so on. We'll be meeting hams, of course. If you are in electronics you may find some products to import, some firms which want your products, or firms to make things for you. These shows are about the only practical way to reach the smaller businessmen in Asia.

If you're interested in racking up some memories for a lifetime, drop me a note and I'll see that you get the dope on the tour. I've been on it twice now and find it first rate.

AN ARRL RESPONSIBILITY

Many years ago, an amateur organization was formed for the main purpose of providing lobbying for the hobby and for funding legal fights against laws which would be seriously harmful to the hobby. The League spent a fortune to put that new organization out of business, fearing any rivals...even for purposes for which they were not responsible.

Okay...this, to my mind, puts some responsibility on their shoulders to stand up and fight when restrictive laws are passed which are harmful to amateur radio. A case in point is a recent ordinance passed by the city of Burbank, Illinois...and this one is hard to believe.

Firstly, they just recently passed a one-year moratorium on issuing any permits for amateur antennas. Secondly, there is an $11 yearly fee for the inspection of each antenna, with a $10 follow-up fee if the antenna does not pass inspection and has to be reinspected.

Even antennas already in place must be registered, with a lot of legal details plus a proof of bond, proof of insurance on the antenna, proof of inspections, and so on. The bond, by the way, requires those responsible for the installation to put up $5,000 which is kept by the city. The wording of the ordinance could be construed to force any amateur putting up his own antenna to put up this $5,000 bond.

The real capper is the last part of the law which makes it illegal to cause any interference to radios, televisions, musical instruments, hi-fis, and so on. The fine set for this is a minimum of $25 and a maximum of $1,000 for each offense.

This sort of mischief *must* be fought. If it is permitted to stand in one city we can only expect it to proliferate, with each city pointing to the previous ones for legitimacy of the law. Yet fighting laws such as this, which seem silly, but which *are* laws, is an expensive undertaking. Who is going to pay to fight these laws?

I realize that there are a lot of amateurs who believe that *any* law must be obeyed and that it is un-American to even try to fight laws, good or bad. The fact is that there are a lot of really bad laws around and we either have to fight them or else give up more and more of our freedom.

You know, these same television viewers who gang up to force hams off the air will be the first ones to be screaming for ham communications when an emergency strikes. Speaking of emergency communications, the more we can organize this aspect of amateur radio, the stronger case we'll have when we have to deal with idiots such as the ones who put through the Burbank ordinance. Trying to reason with them as mere hobbyists trying to enjoy our hobby won't cut a lot of mustard.

It's funny about our laws. There has been a lot of fuss lately about driving and drinking, yet the courts seem to be fighting the laws and doing all they can to make sure that these drunken turkeys are back in cars again. We had one up here who had a record of drunk driving...and being let loose. He got soused one night, got behind the wheel ...turned his truck over... some people helped him turn it back again and he went on a few minutes later to wipe out three kids when he drove over the line into their lane. The police gave him a drunk meter test, but the court wouldn't allow the results to be mentioned in the trial. And so it goes with laws.

As far as crazy laws are con-

NEWSLETTER OF THE MONTH

This month marks the 12th part of *73*'s Newsletter of the Month series. It seems appropriate to close the first year of the contest by reviewing our eleven winners.—N8RK.

73's August, 1981, pick was the Richardson Wireless Klub's *Chawed Rag*. We appreciated their decision to cover upcoming club activities rather than the minute details of what went on at the last club meeting.

September's choice, *The Birmingham Amateur Radio Club Newsletter*, offered some good technical information. They included details about a simple RTTY station as well as featured a monthly "Technical Corner" in which real-life problems were discussed.

The October winner came from the San Diego Repeater Association. *Squelch Tales* boasts several pages of paid advertising each month. This defrays the publication costs, leaving the club's resources available for other projects.

The name *Squelch Tale* (this time with no "s") popped up again in November. We applauded the Chicago FM Club for their newsletter's eye-catching appearance: a consistent, clean-looking layout that ensures readers will spend some time with each issue.

Rounding out the 1981 winners was *The Scuttlebutt*, published by the Yankee Clipper Contest Club. The Clippers leave no stone unturned in a quest for club members who can provide connections to keep the cost of producing the *Scuttlebutt* to a minimum.

The Wheaton Community Radio Amateurs' *The Hamletter* caught our eye in January, 1982, with its two-color printing job and large number of black and white photos. *The Hamletter* masthead gives more than a list of officers; you'll also find details about when the club meets each month and where to look for the local repeaters and nets. These kinds of details make a newsletter friendly and helpful to new readers.

Humor was a key feature in the February winner, *The National Hampoon*. This publication of the Cleveland-based South East Amateur Radio Club relates a lot of information about the doings of individual members in a good-natured, fun way.

A statewide organization, the Wisconsin Association of Repeaters, was recognized for its newsletter in the March, 1982, issue of *73*. Our judges said, "A newsletter editor needs to keep in mind the audience he is trying to reach; if he gives his specialized audience the specialized information that they joined together to learn, they will be happy both with the newsletter and the club."

April's pick, the Metroplex Amateur Radio Communications Association newsletter, was recognized for its beautiful layout. This publication is another example of utilizing the talents of your club members—the editor is a commercial artist.

The May winner, *Kansas Amateur Radio*, is a good example of the fact that a publication doesn't always need the backing of a club. This statewide newsletter is a nonprofit venture that relies on readers for financial and editorial support. The result is very impressive.

Rounding out the first year of *73*'s Newsletter of the Month Contest was *The Log*, published by the Northern Ohio Amateur Radio Society. *The Log* includes something for everyone: reports for awards chasers, the contest crowd, DX hounds, traffic handlers and Novices.

cerned, we need to keep our eyes out for them and make sure that the ARRL, our *only* national club, is held responsible for our protection. Remember that they are our *only* club because they have spent the money it took to shoot down all the others. I'm not pot-shotting the League—only pointing out the facts and the responsibilities which we, as members, have to hold them to.

GENERAL NOTES

Every now and then a reader writes in with indignation that he (or she, rarely) has written me a letter and I have not personally answered. First, let me assure you that I do, indeed, read my mail. If you write to me, I will get the letter. The odds are not so good that you will get an answer, for the simple reason that I am but one person and you, the reader, are one of about 750,000 who read my magazines each month. You get the picture?

The average magazine editor writes a paragraph or two a month, an exercise not likely to get many readers fired up into a letter-writing frenzy. My extended editorials in five monthly magazines seem to flip the more delicately balanced (unbalanced?) readers into an ennui which is only surmounted by a long letter to Wayne...some enthusiastic and others vituperative. I seem to have a halo when viewed from some angles and distinct horns from others.

The fact is that I am someone who is trying mightily to make up for a deprived childhood. I really wanted to get a small printing press when I was a kid and have been taking out the resulting frustration on a growing number of not very innocent bystanders. I've got one now and I am having a ball.

Mind you, whether I can answer or not, I *do* want to hear from you. If you have anything to tell me about some of my editorials, I am always open to more data. Emotional reactions? No. Reasoned arguments? Sure. And if you run into newspaper or magazine clippings I might have missed, I would really appreciate getting them. You probably already know about my interests, such as anything to do with amateur radio, microcomputers, education, UFOs, radar, TVRO... things like that.

If you have a subscription problem, I'm sympathetic but almost as helpless as you are. Send word of your problem to *73* Subscription Dept., Box 931, Farmingdale NY 11737, and give *all* of the details. If this manages to fail to help after about six weeks, the next step is to write to the Circulation Manager, *73 Magazine*, Peterborough NH 03458. If that doesn't get action, try General Manager Debra Boudrieau, Wayne Green, Inc., 80 Pine Street, Peterborough NH 03458. If that, too, fails, let me know and I will rattle the chains.

If you need a back issue, try your best to identify it. We don't have a staff sitting around ready to try to find articles via a clue or two. Check our yearly index for hints. Check our Radio Bookshop for back issue prices... if we have the issues.

We have just enough people here to barely get the magazine out each month, so there is no one sitting around to give technical help or to design circuits for you. If you do have a question, please send it to the Technical Editor, *73 Magazine*, Peterborough NH 03458, complete with an SASE...and then hope that he gets some time. For the most part, you want to try to deal with the author of an article, remembering that he, too, may be up to here in trying to keep up with correspondence. It is not unusual for an author to get a thousand letters after a particularly interesting article. Now, how is he going to handle all of that?

ARTICLES

In the main, we are looking for construction projects. I have this bee in my bonnet about getting hams into building again, even if I have to drag them kicking and screaming into it...as I did with FM and repeaters. Boy! Did the readers hate FM when I started with *that*!

Articles are simple to write. You must type them in upper- and lowercase characters. You must double-space and leave generous margins on the pages for editing. We are now able to accept articles written on your TRS-80 I and III. Send in both the disk and a double-spaced printout. Then we will be able to do the editing on the printout and update the disk, finally dumping the edited article from the disk directly into our typesetting system. That will speed things up for us substantially.

We're also looking for articles which may help encourage schools to set up ham clubs. I feel that the future of both amateur radio and the technology of our country depends on this development.

Photos are most helpful in making the article interesting for the readers. If you have built a gadget and are not equipped with a first-rate camera, please send in the unit so that we can shoot it. We have a Mamiya RB-67 and can do a professional job. No more fuzzy Polaroids, okay? It takes a large-format camera and good lighting to turn out a good photo.

One more thing: Don't ever, ever send your article to two magazines at the same time.

THE PHONE

My apologies to readers wanting to get through to me on the phone. What with trying to manage six monthly publications, nine separate divisions of the company, do consulting, get to shows, give talks, keep up with the literature in two fields, and even ham a bit, my time even for telephone calls is very limited. This means it is getting more and more difficult to break through to me. But if I don't do that, I won't keep all these things growing...or be able to write all these editorials (*no smart remarks*).

In general, if my calendar permits, I'm available for talks to groups at $1,000 plus expenses for Sherry and me. Consulting runs about $500 a day plus expenses for the two of us, whether it is worth it or not. The same goes for the talks. The steep prices make it so that I have more time to do my work ...though I've had no complaints as yet.

CORRECTIONS

In the review of the CES 635 Microdialer (May, 1982, p. 138), we stated an incorrect price. The correct price for this microphone is $99.95.

Jeff DeTray WB8BTH
***73 Magazine* Staff**

In the April issue, page 10, the article "Watching the Weather" will undoubtedly interest many hams having the old deskfax in their parts closet.

There is, however, one portion of the layout which in my opinion can be simplified and possibly be made less expensive. This involves the need to reduce the drum rpm from 180 to 120 which, in the article, requires a 40-Hz voltage amplifier. The same rpm requirement can be met by leaving the motor as a straight 120-volt, 60-cycle unit and changing the output gearing.

Standard gear catalog listings do not show a 1.0-inch-center distance with the required 30 to 1 ratio. I guess nothing in our hobby comes easy, and a little work is required. There is, however, a gear set which comes close to the 1.0-inch-center distance spacing and the exact ratio.

The data are as follows:

- Worm Gear—32 diametral pitch, face width 7/32, bore: .25 diameter, hub diameter 11/16, projection 5/16, 60 teeth, 1.875 PD; catalog #D-1132, item code 13514.
- Worm—32 diametral pitch (double thread), PD .438, bore 3/16; LTHB item code 12922.
- Source—local industrial distributor handling Boston Gears. The manufacturer is Boston Gear Division, 14 Hayward St., Quincy MA 02171, (617)-328-3300.

Since the center distance will now be 1.156 inches with the new gears instead of the original 1.0 inch, it becomes an easy job with the help of a drill motor and a half-round file to lower the motor 5/32 of an inch. The worm will fit as is, but a new pin hole may have to be drilled. The worm gear must be reworked from a .250-diameter center hole to a .500 diameter. Once installed, the standard input of 120 volts at 60 Hz will drive the drum at 120 rpm.

This will eliminate the 80-kHz oscillator, the divider chain, the 40-Watt amplifier, and, of course, the autotransformer.

Glendale NY 11385

THE POSTMAN RETURNS

From Guam to Austria, Alaska to Florida, hams from all over the globe responded to the 1982 edition of the annual Fun! poll. The results, as always, were fascinating, and I wish to thank everyone who participated. I also want to thank my postman, who once again risked his back delivering all those envelopes.

Frankly, what always astounds me about this poll is not only the number of people who take the time to fill out a rather lengthy questionnaire, but also the number who write very long and generally thoughtful letters. Amateur radio will always be a vital hobby as long as there are people around who care about its future.

So thanks once again to the 1,016 of you who wrote in. Here's what you had to say.

ELEMENT 1—BACKGROUND

1) Sex:
A) Male—91% B) Female—9%
A three percent increase in the number of female amateurs over last year. An encouraging trend, but not conclusive enough to indicate a real trend.

2) Age:
A) 15 or below—5% B) 16-21—6% C) 22-39—49% D) 40-59—27% E) 60 and above—13%
Not very encouraging for our hobby's future.

3) License class:
A) Novice—6% B) Technician—10% C) General—30% D) Advanced—40% E) Extra—14%
Compared to last year, seems like there's been an upswing in upgrading.

4) Number of years licensed:
A) 1 year or less—4% B) 1-5 years—33% C) 6-10 years—8% D) 11-20 years—29% E) 21 years and up—26%
The old-timers reign.

5) Do you have a new (post-March '78) call?
A) Yes—45% B) No—55%
The new calls have an 8% increase over last year.

6) How many hours a week do you devote to amateur radio?
A) 0-1 hour—5% B) 2-5 hours—29% C) 6-10 hours—44% D) 11-20 hours—16% E) 21 or more hours—6%
About the same statistics as last year.

7) Which HF band do you most use?
A) 80-75 meters—15% B) 40 meters—20% C) 20 meters—21% D) 15 and/or 10 meters—35% E) Don't operate HF—9%
As the sunspots diminish, so does 15- and 10-meter operation—down from 43% last year.

8) Which VHF-UHF band do you most use?
A) 6 meters—3% B) 2 meters—71% C) 220 MHz—6% D) 420 MHz and/or up—1% E) Don't operate VHF-UHF—19%
Spread out, guys!

9) Which mode do you most use?
A) SSB—41% B) CW—20% C) FM—30% D) RTTY—5% E) Other—4%
If CW is so great, why does its popularity keep dropping?

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenditures.)
A) \$0-\$250—39% B) \$251-\$500—30% C) \$501-\$1,000—24% D) \$1,001-\$2,500—4% E) \$2,501 and up—3%
A continued downward trend.

ELEMENT 2—SOCIAL CHARACTERISTICS

11) Has amateur radio influenced your career choice?
A) Greatly—25% B) Somewhat—26% C) Not at all—49%
Quite an impressive statistic, really.

12) Do you answer QSLs with no return postage?
A) Yes—76% B) No—24%
The fact that the word "Novice" was eliminated from this question, plus two postage increases, might account for the 20% positive response drop.

13) Politically, how would you define yourself?
A) Conservative—40% B) Middle-of-the-road—51% C) Liberal—9%
I've always felt hams were a pretty conservative lot, and it looks like my suspicions were correct. Being a C person, I feel pretty lonely.

14) Do you think amateur radio will exist 20 years from now?
A) Yes—87% B) No—13%
Hams are a pretty optimistic lot.

15) Have you ever had a fight with a family member over amateur radio?
A) Yes—71% B) No—29%
Wow! I want the first aid concession at the next hamfest.

16) Do you have any relatives who are hams?
A) Yes—49% B) No—51%

17) Are most of your friends (more than half) hams?
A) Yes—40% B) No—60%
Takes one to know one—almost.

18) Did you ever use a "cheat book" (not counting the ARRL *License Manual*) to upgrade your license?
A) Yes—16% B) No—84%
No comment.

19) If someone offered you five million dollars, tax-free, on the condition that you give up amateur radio forever, would you?
A) Yes—81% B) No—19%
We raised the ante by four million over last year and got 20% more takers. As for the other 19%, I still say every man has his price. How about 10 million?

20) Do you belong to a local ham radio club?
A) Yes—45% B) No—55%
Not good enough.

21) Have you ever attended a ham flea market?
A) Yes—79% B) No—21%
If you haven't, you don't know what you're missing.

22) Have you ever attended the Dayton Hamvention?
A) Yes—24% B) No—76%
I haven't made it since 1978, but it was a gas!

23) Would you pay five dollars to join the ARRL if they offered no magazine, QSL services, awards, or technical and instructional help?
A) Yes—22% B) No—78%
Guess it must be that great magazine that makes the League. I, for one, love to regale my friends on 15 with the latest activity reports.

24) Would you like to see another national organization compete with the ARRL?
A) Yes—22% B) No—78%
Hoo boy! Did I raise a hornet's nest with this one. One respondent even went so far as to call me a rabble-rouser. I take no stand on this question, but judging from the results, I certainly wouldn't invest my money in the stock of a competitor.

ELEMENT 3—OPERATING HABITS

25) Would you favor a licensing system that had only two classes: Novice and General or Communicator and General?
A) Yes—58% B) No—42%
So much for incentive licensing.

26) Would you like to see the FCC turn over amateur testing responsibility to clubs?
A) Yes—61% B) No—39%
Many of those who were against were afraid of abuses.

27) Do you think religious and politically-oriented nets have a place in ham radio?
A) Yes—79% B) No—21%
Hey, you guys who picked B. Haven't you ever heard of free speech?

28) Should contests be outlawed?
A) Yes—31% B) No—69%
Emotions ran hot and heavy on this one.

29) Do you think the FCC should assign exclusive frequencies and times to nets?
A) Yes—7% B) No—93%
Not a very attractive proposition.

30) Do you think the FCC should assign exclusive frequencies to repeaters?
A) Yes—20% B) No—80%
I don't like the idea, either.

31) Should there be a no-code, VHF and above, "Digital class" license? This license would require a heavy theory test and carry no phone or CW privileges (except perhaps for ID purposes).
A) Yes—34% B) No—66%
I can't figure it: Some letters were downright hostile to the influx of computer users on the bands, as if they were taking over the hobby. Many respondents seemed to welcome the digital ticket idea, but not enough to make a majority.

32) Should there be a no-code 220-MHz, "Communicator class" license? This license would require a moderately difficult theory test and carry only F3 privileges at a maximum of 50 Watts.
A) Yes—41% B) No—59%
A hard core of respondents seemed to be against dropping the code test for any type of license.

33) Do you own a microcomputer?
A) Yes—39% B) No—61%
I can't see how a technically-inclined person can be without one.

34) What sort of CW sending device do you most often use?
A) Straight key—56% B) Keyer—25% C) Bug—4% D) Keyboard—6% E) Never operate CW—9%
Last year, I accidentally left out bugs and received scores of letters asking why. This year, I insert the classification and find out only 4% use them. Can't win.

35) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes—75% B) No—25%
Compared with last year, our skills are diminishing.

36) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes—11% B) No—89%
About the same as last year.

37) Do you think the FCC affects amateur radio in a positive manner?
A) Yes—48% B) No—52%
A little more positive than last year.

38) Do you ever speak to foreign, non-English-speaking hams in their own language?
A) Always—3% B) Sometimes—15% C) I attempt it—25% D) Rarely—6% E) Never—51%
No substantial change over last year.

39) Do you feel yourself competent to replace the finals in a tube-type rig?
A) Yes—91% B) No—9%
Does anyone still own a tube rig? Only kidding!

40) Do you feel yourself competent to replace the finals in a transistor-type rig?
A) Yes—80% B) No—20%
A soldering iron? I thought it was an electric cigar!

41) Have you ever built an electronic project from a kit?
A) Yes—98% B) No—2%
A ham isn't a ham unless he's unpacked all of those little brown bags before opening the instruction booklet

42) Have you ever "home-brewed" an electronic project from a book or magazine?
A) Yes—75% B) No—25%
A bit down from last year. For shame on those who haven't.

43) Have you ever designed your own electronic project?
A) Yes—61% B) No—39%
Hasn't everyone?

44) What do you think of contesting?
A) Great—15% B) Good—20% C) Okay—17% D) Don't like it—29% E) Despise it—19%
You're 59 New York.

45) What do you think of DXing?
A) Great—40% B) Good—31% C) Okay—19% D) Don't like it—5% E) Despise it—5%
QSL via the bureau.

46) What do you think of repeaters?
A) Great—35% B) Good—30% C) Okay—22% D) Don't like them—8% E) Despise them—5%
Wait for the beep.

47) What do you think of traffic handling?
A) Great—10% B) Good—35% C) Okay—40% D) Don't like it—14% E) Despise it—1%

48) Do you plan to use Phase III OSCAR within a year of its launch?
A) Yes—28% B) No—72%
Looks like that passband is going to get pretty crowded.

49) Do you plan to use the new 10.1-MHz band within one year of its opening?
A) Yes—40% B) No—60%
That should be around Jan. 1, 2065, at the rate the U.S. Senate is moving.

50) Do you believe amateurs should have the right to build, use, and sell equipment for the reception of subscription television?
A) Yes—24% B) No—76%
I should have left "sell" out of the question. Seems many amateurs think they should be able to pirate signals for their own use, but not for others.

SELECTED COMMENTS

Too many private repeaters tying up amateur frequencies. Some systems have only three people on them.—KB6BO.

Morse code should be outlawed as a requirement, although I love it.—K6XR.

Amateur radio needs quality, not quantity. We should strive to keep the standards high.—WB5ZDP.

We will keyboard and computerize ourselves away from the human fashion of hamming.—W4YDL

Let's have more polls—these are FUN!!—KF4W.

I think the Communicator class is a very good idea. I am partially deaf. Code is very hard for me. This may give deaf people a chance to communicate by RTTY.—KA7CYE.

After 21 years of hamming, I earned my Extra class license and not a word of congratulations from the ARRL or any manufacturer of ham gear.—KD1J.

This has been the only column you've put in print that I knew all the answers to.—N7AVM.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CANADA CONTEST

Starts: 0000 GMT July 1
Ends: 2400 GMT July 1

Sponsored by the Canadian Amateur Radio Federation (CARF), the contest is open to all amateurs, and everybody works everybody. Entry classes include single operator/all bands, single operator/single band, and multi-operator/single transmitter/all bands. There are separate single-operator QRP (5 W dc, 10 W PEP out) and single-operator non-Advanced amateur classes.

Use all bands from 160 to 2 meters on CW and phone combined. All contacts with amateur stations are valid. Stations may be worked twice on each band, once on CW and once on phone. No crossmode contacts, and no CW contacts in the phone bands are allowed.

EXCHANGE:

Signal report and consecutive serial number starting with 001; VE1 stations should also send their province (NS, NB, PEI).

SCORING:

Score 10 points for each contact with Canada, 1 point for contacts with others. VEØ counts as Canada. Score 10 points for each contact with any CARF official news station using the suffix TCA or VCA. Multipliers are the number of Canadian provinces/territories worked on each band, on each mode (12 provinces/territories × 8 bands × 2 modes for a maximum of 192 possible multipliers). Contacts with stations outside Canada count for points but not multipliers.

FREQUENCIES:

Phone—1810, 3770, 3900, 7070, 7230, 14150, 14300, 21200, 21400, 28500, 50.1, 146.52.

CW—1810, 3525, 7025, 14025, 21025, 28025, 50.1, 144.1.

Suggest phone on the even hours (GMT), CW on the odd hours (GMT). Since this is a Canadian-sponsored contest, remember to stay within the legal frequencies for your country!

AWARDS:

A plaque will be awarded to the highest score single operator/all bands entry. Certificates will be awarded to the highest score in each category in each province/territory, US call area, and DX country.

ENTRIES:

A valid entry must contain log sheets, dupe sheets, a cover sheet showing claimed QSO points, a list of multipliers, and a calculation of final claimed score. Cover sheets and multiplier check lists are available. Entries should be mailed within one month of the contest, with your comments, to: CARF, PO Box 2172, Stn. D, Ottawa, Ontario K1P 5W4, Canada.

Results will be published in *TCA*, the Canadian amateur magazine. Non-subscribers may include an SASE for a copy of the results.

INTERNATIONAL QRP CONTEST

Starts: 1500 GMT July 17
Ends: 1500 GMT July 18

The first International QRP Contest is being sponsored by the World QRP Federation (WQF) and offers a variety of awards for leading stations. This is a CW-only event with separate categories for single- or multi-operator stations, and for those operating fixed or portable. Multi-operator stations may be on the air for the entire 24-hour contest period, while single-operator entries must be off the air for at least an eight-hour period. All stations may be worked once per band for QSO and multiplier credits.

EXCHANGES:

RST, QSO serial number, and class (599 001/2D). Add X after RST if crystal-controlled (559X 001/2D).

FREQUENCIES:

The traditional QRP frequencies will be utilized: 1810, 3560, 14060, 21060, and 28060, all plus or minus QRM.

OPERATING CLASSES:

1 = single operator, 2 = multi-operator, A = fixed station up to 2 Watts input or 1 Watt output, B = fixed station up to 10 Watts input or 5 Watts output, C = portable station up to 2 Watts input or 1 Watt output, D = portable station up to 10 Watts input or 5 Watts output, and E = QRO stations of more than 10 Watts input or 5 Watts output.

SCORING:

Count 1 point for QRP to QRO contacts, 2 points for QRP to QRP. For multipliers, count 1 if both stations are in the same country, 2 if the other station is in another country on the same continent, 3 if the other station is in another country and on another continent. For scoring purposes, all call areas within a country are counted as multipliers (e.g., 10 for W/K, 8 for VE, 10 for PY, etc.). For crystal stations with a maximum of three crystals per band, QSO and multiplier points are doubled. Contacts with crystal-controlled stations count double. Band points are the QSO points per band times the multiplier points per band. Final score is the sum of band points from each band.

AWARDS:

DL-AGCW will provide awards for fixed station leaders and band leaders. QRP ARCI will provide plaques to the first place single- and multi-operator portable stations worldwide plus certificates for the multiple- and single-operator portable station in each country with two or more entries.

ENTRIES:

Send logs within six weeks of conclusion of the contest as follows: fixed stations to Siegfried Hari DK9FN, Spessartstrasse 80, D-6453 Seligenstadt, West Germany; portable stations to William W. Dickerson WA2JOC, 352 Crampton Drive, Monroe MI 48161, USA.

INTERNATIONAL WORLDWIDE DX SSTV CONTEST

Starts: 0000 GMT July 17
Ends: 2400 GMT July 18

This is the second annual DX SSTV contest sponsored by *A5 ATV Magazine*. This is a 48-hour SSTV video contest using 80 through 10 meters within the recommended SSTV calling/operating frequencies listed below. To encourage use of all bands, extra bonus points are granted on the 10-, 15-, 40-, and 80-meter band segments. Single- and multi-operator stations are recognized with cross-band contacts not permitted. Individual contacts count only

once per band with repetitive multi-band contacts acceptable.

Callsigns and video reports must be in "video" form. Mugshots of the station operator, family, or friends can count only once. Slower clock-rate speeds are encouraged in either 128/16.5-second or 256/31-second timebases. Color work must contain a minimum of 2-color overlay to qualify with standard RGB frame transmissions. Motion SSTV must have a minimum of 2 frames sent with automatic-receive switching circuitry or manually operated switching by the receiving operator, and 64 × 64 "quadrant" storage of no less than 4 separate pictures with replays.

SCORING:

Each SSTV two-way contact is worth 5 points within the same country and 10 points for DX out-of-country. Contact bonus points are available as follows: mugshots—1 point, slow speed—2 points, quad frame—3 points, motion SSTV—4 points, high resolution—5 points, and *color* SSTV—10 points.

A band multiplier of 3 can be claimed for contacts on 40 and 30 meters, and 2 for contacts on 10 and 15 meters. Stations with over 25 DX countries worked—add 25 points, 50 DX countries—add 50 points, and over 100 DX countries—add 100 points!

FREQUENCIES:

Advanced/Extra—3845, 7220, 14230, 21340, 28680, 50.150.
General—3990, 7290, 14340, 21440, 28680, 50.150.

AWARDS:

First-place winner receives 3-year subscription (worth $60) to *A5 ATV Magazine* with front-cover picture plus a Gold Certificate. Second- and third-place winners receive one-year subscriptions and Gold Certificates. All entries regardless of score *receive* Gold Certificates suitable for framing. Results will be in the November issue of *A5 ATV Magazine*.

ENTRIES:

Submission of logs and totaled scores must be postmarked no later than August 1st and submitted to: Contest Manager, *A5 ATV Magazine*, PO Box H, Lowden IA 52255-0408. Logs will be returned as will any photos, etc. Some log sheets and DX country lists are available from WB0QCD.

CW COUNTY HUNTERS CONTEST

Starts: 0000 GMT July 24
Ends: 0200 GMT July 26

The CW County Hunters Net invites all amateurs to participate in this year's contest. All mobile and portable operation in less-active counties is welcomed and encouraged. Stations may be worked once on each band, and again if the station has changed counties. Portable or mobile stations changing counties during the contest may repeat contacts for QSO points.

EXCHANGE:

QSO number; category (P for portable, M for mobile); RST; state, province, or country; and US county. Stations on county lines give and receive only one QSO number, but each county is valid for a multiplier.

FREQUENCIES:

Frequencies are 3575, 7055, 14070, 21070, and 28070. It is strongly requested that only P or M category stations call CQ or QRZ on 40 meters below 7055 and on 20 meters below 14070, with all other stations spreading out above those frequencies.

SCORING:

QSOs with fixed stations are 1 point, QSOs with portable or mobile stations are 3 points. Multiply the number of QSO points times the number of US counties worked. Mobiles and portables calculate their score on the basis of total contacts within a state for the state certificate, and calculate their score on all operation if they operated from more than one state in competition for the High Portable or High Mobile Trophy.

AWARDS:

Certificates will be awarded in three categories:

1) Highest fixed or fixed-portable station in each state, province, and country with 1,000 or more points.

2) Highest station in each state operating portable from a county which is not his normal point of operation, with 1,000 or more points.

3) Highest station in each state operating mobile *from* 3 or more counties with a minimum

RESULTS

RESULTS OF *A5 ATV MAGAZINE* WORKED ALL STATES SSTV CONTEST

(Full results appeared in the June issue of *A5 ATV Magazine*, PO Box H, Lowden IA 52255-0408.)

The top 5 entries from 59 entries received:

1st—Luis Chartarifsky XE1LCH
2nd—Roland Soucie N6WQ
3rd—Larry Benson K9KQO
4th—John Hudak III KA3X
5th—Harry Harchan W2GND

of 10 QSOs in at least each of 3 counties.

Trophies will be awarded to the highest single-operator station in the US in categories P and M. The Awards Committee may issue additional awards.

ENTRIES:

Logs must show category, date/time in GMT, station worked, band, exchanges, QSO points, location, and claimed score. All entries with 100 or more QSOs *must include a check sheet of counties worked or be disqualified from receiving awards*. Enclose a *large* SASE if results are desired. Logs must be postmarked by September 1st and sent to: CW County Hunters Net, c/o Jeffrey P. Bechner W9MSE, 673 Bruce Street, Fond du Lac WI 54935.

DX

Chod Harris VP2ML
Box 4881
Santa Rosa CA 95402

CHINA

China. The very word conjures up visions of mystery and Marco Polo. And to DXers China means Number 1 on everyone's Most Wanted List. The *DX Bulletin* annual survey (the benchmark of the Most Wanted Lists) continues to show China in the top spot again this year.

Over the past few years, the China rumors have been flying thick and fast. "China will be opening soon." "Hundreds of China stations will start operating next week." And so on. One prominent New Zealand amateur came within inches of spurring China into the amateur radio arena, but his US citizenship sabotaged the effort.

The positive attitude of the China authorities encourages the rumors and rumor-followers. Unlike many countries where amateur radio is flatly prohibited, China has been enthusiastic about the future role of amateur radio. It is just a matter of time.

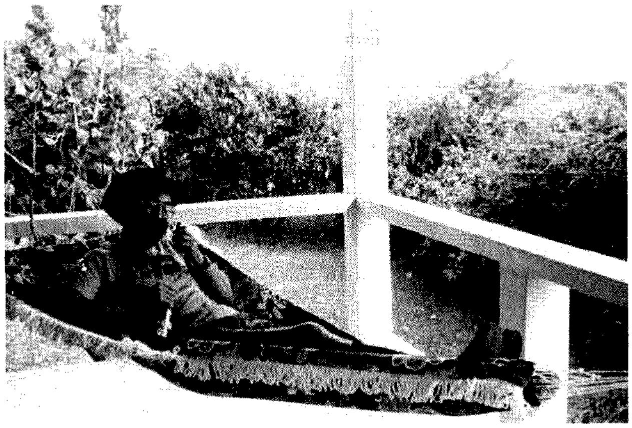
That time may have finally come. On March 29, BY1PK appeared on 15 meter CW, working (of course) JAs.

Tom Wong VE7BC clearly performs the role of hero in this operation. His tireless efforts over the past few years have just begun to provide fruit. Tom has been instrumental in funneling equipment, training materials, books, and expertise from the ARRL and other stateside organizations to the appropriate authorities in China.

The BY1PK operation represents not a one-shot, contest-style operation, but the reawakening of amateur radio in the most populated country in the world. Although China will move slowly in the amateur radio field, it is moving in the right direction, and the next few years should see that Number 1 ranking slip further and further down the Most Wanted survey.

The "Other" China

The neophyte DXer, unfamiliar with the prefix BY, might turn to the International Prefix Allocation List to locate the source of the signals. The list shows all the B callsigns as belonging to China. The *Callbook* shows no China amateurs. Or does it?



In addition to working on his monthly DX column for 73 Magazine, *Chod Harris VP2ML leads a very demanding life. Here he's shown slaving away at his VP2 QTH.*

Just before the BY listing in the *Callbook* is the BV listing: two amateurs. If the BY call signifies China, what does the BV signify? Answer: The "other" China—our former ally, Taiwan, the Republic of China.

Not to be confused with the People's Republic of China, Taiwan is the last refuge of the anti-Communist forces driven out of mainland China after World War II. The Nationalist government of Taiwan considers itself to be the legitimate authority over all of China, hence the BV callsign.

But only two amateurs in a country as rich and well populated as Taiwan? A small amateur population is more typical of a smaller, undeveloped country, a distinction hardly appropriate for industrial Taiwan. So why only two hams?

The question is not why there are only two amateurs in Taiwan, but rather why there are any amateurs at all. Taiwan considers itself still at war with the mainland government. Both sides would like the other to go away, to reunite the country (shades of Korea and Vietnam here). And military governments under states of war or emergency are notoriously reluctant to allow free use of the amateur bands.

One of the very first proclamations under the martial law in Poland was the crackdown on amateur radio activities. Even in the US, amateur radio activity ceases during wartime.

We can understand why a country at war would feel uncomfortable about permitting unrestricted use of the amateur bands. The independence of the amateurs and the tremendous flexibility of amateur equipment are powerful communications tools to those on the outs with the government.

The increasing use of amateur radio gear in illegal drug shipments demonstrates that ham radio equipment and expertise can be a disturbing factor in sensitive political differences. Hence many countries simply prohibit all amateur radio activities; witness Albania, for example.

So we return to our original question: Why is there any amateur radio activity at all from a divided country engaged in a "civil war"?

First, there is really only one amateur in Taiwan, with two callsigns: Tim Chen operates BV2A on CW and BV2B on SSB. Somehow a single individual has obtained permission to operate amateur radio in Taiwan. But that permission is probably the most restricted amateur radio authority short of a flat-out ban. Tim's operating authority restricts him to specified times and frequencies. Can you imagine your radio license specifying the exact frequency and time of operation? It would certainly put a crimp in your DXing.

Fortunately for DXers throughout the world, Tim maintains his activity, keeps to his schedules, and regularly provides QSLs from the "other" China.

Look for Tim Wednesdays between 1200 and 1600Z on one of the following frequencies: 14025, 14040, 14218, or 14250. Tim usually shows up on CW first and switches to SSB a little later. Tim also has operating permission Saturday from 2300 to 0200Z. When band conditions permit 15-meter operation, Tim operates on 21030, 21110, 21270, and 21350. And more recently Tim has added the 10-meter frequency of 28530 to the possibilities.

Tim QSLs consistently either direct to Box 101, Taipei, Taiwan, Republic of China, or via QSL manager K2CM at his *Callbook* address.

If you hear BV2B on 20 meters and have trouble breaking through the pileup, perhaps your choice of phonetics could use improvement. Let's continue our discussion from last month.

PHONETICS

Last month we discussed the different kinds of phonetic call-

signs: standard, place names, and "cute" phonetics. Now we look at how you evaluate your own choice of phonetics and how you can select alternate phonetics.

A phonetic call should have two characteristics: The call must be unambiguous, and it should punch through the pileup. Removing ambiguity from a potential phonetic callsign is easy: Pick easily recognized words which have no common homophones (a word that *sounds* similar, but is spelled differently).

A couple of examples of what *not* to do might illustrate this: A W5 called me using "Motel" as a phonetic. The confusion between this and "Hotel" is obvious. And one Field Day, an amateur called me with the phonetic suffix, "Fuzzy Wuzzy Wabbit!" I was forced to ask for clarification: "Is that R as in Rabbit or W as in Wabbit?" Back came the reply, "Wabbit! Wabbit, wabbit, wabbit!" Memorable, but not very effective in a DX pileup. Stick with less confusing phonetics.

Selecting a phonetic call with punch is more difficult. I suggest going to a station equipped with an oscilloscope monitor of the outgoing signal. Try different phonetics and combinations of phonetics while watching the scope. Look for those phonetics which give the greatest average output, or the "blockiest" output pattern. Lacking a scope, try watching the relative power output meter on your rig. Again, try to keep the average power as high as possible.

The two "cute" phonetics mentioned last month (W1NoGood and WA9BlackWhiteYellow) are very effective because they share the two most important characteristics of good phonetics: They are unambiguous and they really cut through the pileups. Watch your output meter while saying "No Good" or "Black White Yellow" to see what a good phonetic does for your average output.

Also, individual amateurs in foreign countries might have a particular difficulty with one of your choices. For one reason or another, an amateur might have a block against that particular phonetic and fail to understand even under good conditions. Be flexible, and don't be afraid to shift to a backup set of phonetics when the first fails after a couple of tries. On the other hand, wait until the DX station is obviously struggling with the call before you switch your phonetics. You use phonetics to *reduce* ambiguity, and throwing dozens of different phonetics at the DX station will more likely confuse the poor DXer and decrease the chances for a successful contact. Keep your different phonetics to a minimum and use an alternate set only when necessary.

I found that three sets of phonetics covered almost any situation. A short, punchy set worked for good conditions, where I knew my call would get through, or for tailending: "Sugar Queen Baker." I tried a slightly longer set when the first one failed: "Sierra Quebec Bravo." This set had the advantage of very high average output; I could really hang the relative power output meter up with Number 2. The final set was the lousy condition set: "Santiago Quebec Bolivia," to be used only under adverse circumstances, when repetition of the other two failed miserably. I used this phonetic *after* contact was established. If the DX station did not have my call correctly, or continued to struggle with the call, I would switch to the longer phonetic.

Many amateurs use phonetics for the *suffix* of their call but ignore the *prefix*. When the only stateside calls began with K, W, WA, and WB, the possibilities for error remained small. But even the advent of WD calls rapidly discredited this practice. The current proliferation of similar sounding prefixes (KB, KD, KE) makes the use of phonetics for both prefix and suffix mandatory.

Testing Your Choice

The ideal way to test your phonetics is to get on the air and start throwing your call into pileups. Does the call get through? Do the DX stations get your call correctly? The best test of a given set of phonetics is success. If it works, try it again. If it works again and again, use it a lot. If it does not cut the pileup, try another combination until you find the most effective.

One sure sign that a given phonetic doesn't work for your combination of voice and station is a pattern of consistent error when the DX station comes back to you. For example, I quickly found that "Whiskey Alpha One Sierra Queen Bravo" was often answered with WA1S something B." Watching the output scope showed me the problem: Output dropped to near zero on the "Queen." That letter wasn't getting through. A switch to "Quebec" (although opening the door for confusion with Canadian stations) eliminated the lost letter phenomenon.

More Than One?

After experimenting in front of the output monitor (into a dummy load or empty band, of course) and testing the DX waters in numerous pileups, you will find a phonetic call which meets the requirements of lack of ambiguity and good penetrating power. You will be tempted to use this phonetic call in every DX circumstance. Unfortunately, life, and especially DXing, is not that simple. The best set of phonetics for one band or band conditions might not be competitive at *another* time. A short, snappy phonetic call might be just the thing for 10 meters when it is wide open, but the same combination on 80 might be destroyed by a single static crash.

Finally, phonetics are very personal. What works for one voice, rig, and microphone might not work for another combination. Guest operators at the big contest multi-multis are familiar with this problem. Each operator has to experiment to find the phonetics which work best. Meanwhile, see you in the pileups! Next month we'll *have a* treat for the CW DXers, as we examine zero-beating.

NOTES FROM ALL OVER

JO1CRA gives the following address for WH0AAB: Hide-haru Aimono, 2644 Tsuruda, Utsunomiya-City, Tochigi, 320 Japan. N0BNY reports a July operation from VP2K (on his honeymoon!). Pat also QSLs the VP1MK operation at his home address: 2770 South 13th Street, Omaha NE 68108, with SASE. K9MK/5 handles his own QSLs for his /VP2A and /V2A operations at 6061 Dunson Court, Watauga TX 76148. V2AMK should be QSLed to N0DH/7 at 2031 East Gary, Mesa AZ 85203. And finally Nick Percival 9Y5NP of the Trinidad and Tobago Amateur Radio Society announced the 50 Years of Amateur Radio special prefix for his country: 9Y50. Look for Nick and other Trinidad amateurs using this prefix for the rest of 1982.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

WORKED ALL ZONES

The WAZ award will be issued to any licensed amateur station presenting proof of contact with the forty zones of the world. This proof shall consist of proper QSL cards which may be checked by any of the authorized *CQ* checkpoints or sent directly to the WAZ Award Manager, Mr. Leo Haijsman W4KA, 1044 Southeast 43rd St., Cape Coral FL 33904. Many of the major DX clubs in the US and Canada and most national amateur radio societies abroad are authorized *CQ* checkpoints. If in doubt, consult the WAZ Award Manager. Any legal type of emission may be used, providing communication was established after November 15, 1945.

The official *CQ* WAZ Zone Map, and the printed zone list which follows these rules, will be used in determining the zone in which a station is located.

Confirmation must be accompanied by a list of claimed zones, using *CQ* form 1479, showing the call letters of the station contacted within each zone. The list should also clearly show the applicant's name, call letters, and complete mailing address. The applicant should indicate the type of award for which he is applying, such as all-SSB, all-CW, or mixed. In re-

mote locations and in foreign countries, a handwritten list may be submitted and will be accepted for processing, provided the above information is shown.

All contacts must be made with licensed, land-based, amateur stations operating in authorized amateur bands.

All contacts submitted by the applicant must be made from within the same country. It is recommended that each QSL clearly show the station's zone number. When the applicant submits cards for multiple callsigns, evidence should be provided to show that he or she also held those call letters.

Any altered or forged confirmations will result in permanent disqualification of the applicant.

Include with the application the processing fee (subscribers, $4.00; non-subscribers, $10.00) and a self-addressed envelope with sufficient postage stamps or international reply coupons to return the QSL cards by the class of mail service desired and indicated. *CQ* subscribers should include a recent mailing label (or copy) with application. International reply coupons equal in redemption value to the processing fee are acceptable. Checks should be made out to Mr. Leo Haijsman, WAZ Award Manager.

In addition to the conventional certificate for which any and all bands and modes may be used, specially endorsed and numbered certificates are available for phone and single-sideband operation. The phone certificate requires that all contacts be two-way phone; the SSB certificate requies that all contacts be two-way SSB.

If, at the time of the original application, a note is made pertaining to the possibility of a subsequent application for an endorsement or special certificate, only the missing confirmations required for that endorsement need be submitted with the later application, provided a copy of the original authorization signed by the WAZ manager is enclosed.

Decisions of the *CQ* DX Awards Advisory Committee on any matter pertaining to the administration of this award will be final.

All applications should be sent to the WAZ Award Manager, W4KA, after the QSL cards have been checked by an authorized *CQ* checkpoint.

Zone maps, printed rules, and application forms are available from the WAZ Award Manager. Send a self-addressed envelope, 4" × 9½" with 28¢ postage, or a self-addressed envelope and 2 IRCs. For rulings on borderline areas, consult the WAZ Award Manager.

SINGLE-BAND WAZ

Since January 1, 1973, WAZ awards have been issued to licensed amateur stations presenting proof of contact with the 40 zones of the world on one of the five high-frequency bands, 80-10 meters. Contacts for a single-band WAZ award must have been made after 0000 hours GMT, January 1, 1973. Proof of contact shall consist of proper QSL cards checked by the DX Editor, the WAZ Manager, or an authorized *CQ* checkpoint. Single-band certificates will be awarded for both two-way phone, including SSB, and two-way CW. The single-band WAZ program is governed by the same rules and uses the same zone boundaries.

5-BAND WAZ

On January 1, 1979, the CQ DX Department, in cooperation with the CQ DX Awards Advisory Committee, announced the 5-band WAZ.

Applicants who succeed in presenting proof of contact with the 40 zones of the world on the five high-frequency bands—80, 40, 20, 15, and 10 meters (for a total of 200)—will receive a special certificate in recognition of this achievement.

These rules were in effect as of July 1, 1979, and supercede all other rules. Five-band WAZ will be offered for any combination of CW, SSB, phone, or RTTY contacts, mixed-mode only. Separate awards will not be offered for the different modes. Contacts must have been made after 0000 hours GMT, January 1, 1979. Proof of contact shall consist only of proper QSL cards checked by the WAZ Award Manager, W4KA. The first plateau will be a total of 150 zones on a combination of the five bands. Applicants should use a separate sheet for each frequency band, using *CQ* form 1479.

A regular WAZ or single-band WAZ will not be a prerequisite for a 5-band WAZ certificate. All applications should show the applicant's WAZ number.

After the 150-zone certificate is earned, the final objective is 200 zones for a complete 5-band WAZ. *CQ* is donating plaques for the first 5 winners, after which the applicant will have a choice of paying a fee for his plaque and/or applying for an endorsement commemorating this achievement.

The applications should be sent to the WAZ Award Manager, W4KA. The 5-band award is governed by the same basic rules as for the regular WAZ and uses the same zone boundaries.

THE WPX AWARD

The *CQ* WPX award recognizes the accomplishments of confirmed QSOs with the many prefixes used by amateurs throughout the world. Separate distinctively-marked certificates are available for 2 × SSB, CW, and mixed modes, as well as the VPX award for shortwave listeners and the WPNX award for Novice amateurs.

All applications for WPX certificates (and endorsements) must be submitted on the official application form *CQ* 1051A. This form can be obtained by sending a self-addressed stamped envelope to the WPX Award Manager, Bob Huntington K6XP, 5014 Mindora Dr., Torrance CA 90505. It is highly desirable to use business-size envelopes, 8½" × 11", for this purpose.

All QSOs must be made from the same country. All call letters must be in strict alphabetical order and the entire call must be shown. All entries must be clear and legible.

Certificates are issued for the following modes and numbers of prefixes (crossmode QSOs are not valid for the CW or 2 × SSB certificates): mixed (any mode)—400 prefixes confirmed; CW—300 prefixes confirmed; 2 × SSB—300 prefixes confirmed. Separate applications are required for each mode.

Cards need not be sent but must be in the possession of the applicant. Any and all cards may be requested by the WPX Award Manager or by the *CQ* DX Committee. The application fee for each certificate is $4.00 for subscribers and $10.00 for non-subscribers, or the equivalent in IRCs. All applications and endorsements should be sent to the WPX Award Manager.

Prefix endorsements are issued for each 50 additional prefixes submitted. Band endorsements are available for working the following numbers of prefixes on the various bands: 1.8 MHz—50; 3.5 MHz—175; 7 MHz—250; 14 MHz—300; 21 MHz—300; and 28 MHz—300. Continental endorsements are given for working the following numbers of prefixes in the respective continents: North America—160; South America—95; Europe—160; Africa—90; Asia—75; and Oceania—60. Endorsement applications must be submitted on *CQ* form 1051A. Use separate applications for each mode and be sure to specify the mode of your endorsement application. For prefix endorsements, list only additional call letters confirmed since the last endorsement application.

A self-addressed envelope and $1.00 or 5 IRCs are required for endorsement stickers.

The two or three letter/numeral combinations which form the first part of any amateur call will be considered the prefix. Any difference in the numbering, lettering, or order of same shall constitute a separate prefix. The following would be considered different: W2, WA2, WB2, WN2, WV2, K2, and KN2. Any prefix will be considered legitimate if its use was licensed or permitted by the governing authority in that country since November 15, 1945.

A suffix would designate portable operation in another country or call area and would count only if it is the normal prefix used in that area. For example, K4IIF/KP4 would count only if it is the normal prefix used in that area. For example, K4IIF/KP4 would count as KP4. However, KP4XX/7 would not count as KP7 since this is not a normal prefix. Suffixes such as /M, /MM, /AM, /A, and /P are not counted as prefixes. An exception to this rule is granted for portable operation within the issued call area. Thus, contacts with a special prefix such as WS2JRA/2 count for WS2; however, WS2JRA/3 would count for W3.

All calls without numbers will be assigned an arbitrary Ø plus the first two letters to constitute a prefix. For example, RAEM counts as RAØ, AIR as AIØ, UPOL is UPØ. All portable suffixes that contain no numerals will be assigned an arbitrary Ø.

For example, W4BPD/LX counts as LXØ and WA6QGW/PX counts as PXØ.

THE VPX AWARD

The VPX, or verified prefixes award, can be earned by shortwave listeners (SWLs) who possess QSL cards confirming reception of at least 300 different amateur prefixes. No mode endorsements are available. Applications are submitted to the WPX Award Manager in accordance with the WPX rules.

THE WPNX

The WPNX award can be earned by USA Novices who work 100 different prefixes prior to receiving a higher-class license. The application may be submitted after receiving the higher license, providing the actual contacts were made as a Novice. Prefixes worked for the WPNX award may later be used for credit toward the WPX award.

The rules for the WPNX award are the same as for WPX, except that only 100 prefixes must be confirmed and that applications are sent to the WPX Award Manager.

THE *CQ* DX AWARD

The *CQ* CW DX award and *CQ* SSB DX award are issued to any amateur station submitting proof of contact with 100 or more countries on CW, or SSB. Applications should be submitted on the official *CQ* DX award application.

All QSOs must be 2-way SSB or 2-way CW—crossmode or one-way QSOs are not valid for the *CQ* DX awards. QSLs must be listed in alphabetical order by prefix and all QSOs must be dated after November 15, 1945. Except for the mobile endorsement, all QSOs must be made from the same call area.

QSL cards must be verified by one of the authorized checkpoints for *CQ* DX awards or must be included with the application. If cards are sent directly to the Award Manager, Billy Williams N4UF, 911 Rio St. Johns Dr., Jacksonville FL 32211, postage for their return by first-class mail must be included. If certified or registered mail return is desired, sufficient postage should be included.

Country endorsements for 150, 200, 250, 275, 300, 310, and 320 countries will be issued. To promote multiband usage and special operating skills, special endorsements are available as follows:

- a 28-MHz band endorsement for the 100 or more countries confirmed on the 28-MHz band;
- a 3.5/7-MHz band endorsement for 100 or more countries confirmed using any combination of the 3.5- and 7-MHz bands;
- a 1.8-MHz band endorsement for 50 or more countries confirmed on the 1.8-MHz band;
- a QRPp endorsement for 50 or more countries confirmed using 5 Watts input or less;
- a mobile endorsement for 50 or more countries confirmed while operating mobile. The call area requirement is waived for this endorsement;
- an SSTV endorsement (*CQ* SSB DX award only) for 50 or more countries confirmed using 2-way slow-scan TV;
- an OSCAR endorsement for 50 countries confirmed via amateur satellite.

A fee of $4.00 for subscribers and $10.00 for non-subscribers (or the equivalent in IRCs), to defray the cost of the certificate and handling, is required for each award. An SASE or one IRC is required for each endorsement.

The ARRL DXCC country list constitutes the basis for *CQ* DX award country status. Deleted countries will not be valid for the *CQ* DX award. Once a country has lost its status as a current country, it will automatically be deleted from our records.

All contacts must be with licensed land-based amateur stations working in authorized amateur bands. Contacts with ships and aircraft cannot be counted.

USA-CA AWARD PROGRAM

The United States of America Counties award, sponsored by *CQ*, is issued for confirmed contacts with specified numbers of US counties under rules and conditions hereafter stated.

The USA-CA is issued for seven (7) different classes, each a separate achievement as endorsed on the basic certificate by the use of a special seal for each higher class. Also, special endorsements will be made for all-one-band or -mode operations subject to the rules.

Class USA-500 requires 500 counties, USA-1000 requires 1000 counties and 25 States, USA-1500 requires 1500 counties and 45 states, USA-2000 requires 2000 counties and 50 states, USA-2500 requires 2500 counties and 50 states, USA-3000 requires 3000 counties and 50 states, and the ultimate award, USA-3074-CA, is issued for all 3074 counties in all 50 states. The USA-3074 awardee is given a special honors plaque for a cost of $35.

USA-CA is available to all licensed amateurs everywhere in the world and is issued to them as individuals for all county contacts made, regardless of calls held, operating QTHs, or dates whatever. Special USA-CAs are also available to SWLs on a heard basis.

All contacts must be confirmed by QSL and such QSLs must be in one's possession for identification by certification officials. Any QSL card found to be altered in any way disqualifies the applicant.

For mobile and portable operations, the postmark will identify the county unless information stated on QSL cards makes other positive identification. In the case of cities, parks, or reservations not within counties proper, applicants may claim any one of the adjoining counties for credit (once).

The USA-CA program will be administered by a *CQ* staff member acting as USA-CA custodian, and all applications and related correspondence should be sent directly to him at his QTH. Decisions of the custodian in administering these rules and their interpretation (including future amendments) are final.

The scope of USA-CA makes it mandatory that special record books be used for application. For this purpose, *CQ* has provided a 64-page, 4¼" by 11" record book which contains application and certification forms and which provides record/log space meeting the conditions of any class of award and/or endorsement required.

A completed USA-CA record book constitutes the medium of basic application and becomes the property of *CQ* for record purposes. On subsequent applications for either higher classes or for special endorsements, applicants may use additional record books to list required data or may make up their own alphabetical lists conforming to requirements.

Record books can be obtained directly from *CQ*, 76 N Broadway, Hicksville NY 11801 for $1.25 each. We recommend that two be obtained: one for application use and one for personal file copy.

To apply, make the record book entries necessary for county identity and enter other log data necessary to satisfy any special endorsements (band/mode) requested.

Be sure to have the certification form provided signed by two licensed amateurs (General class or higher) or an official of a national-level radio organization or affiliated club, verifying that QSL cards for all contacts as listed have been seen. The USA-CA custodian reserves the right to request any specific cards to satisfy any doubt whatever. In such cases, applicants should send sufficient postage for return of cards by registered mail.

Send the original completed record book (*not* a copy), certification forms and handling fee. The fee for non-subscribers to *CQ* is $10.00 or 40 IRCs; for subscribers, the fee is $4.00 or 12 IRCs. *CQ* subscribers should include a recent mailing label with their application (or copy). Send to USA-CA Custodian, Ed Hopper W2GT, Box 73, Rochelle Park NJ 07662. For later applications for higher class seals, send the record book or a self-prepared list (per rules) and $1.25 or 6 IRCs (handling charge). For application for later special endorsements (band mode) for which certificates must be returned for endorsement, send certificates and $1.50 or 8 IRCs for handling charges. Note: At the time any USA-CA award certificate is being processed, there are no charges other than the basic fee, regardless of the number of endorsements or seals; likewise, one may skip the lower classes of USA-CA and get higher classes without losing any lower awards credits or paying any fee for them.

SALMON-A-RAMA

The Racine Megacycle Club will be operating W9UDU, a special event station, during SALMON-A-RAMA from July 10th through July 18th, 1982. Operating dates and times: July 10, 11, and 17—1100Z-2300Z; July 18—1100Z-2000Z. Frequency: Fish locators have identified good fishing grounds in the General portion of the phone

bands on 10, 15, and 20 meters. Go fishing for W9UDU and receive a special QSL for an SASE to: W9UDU Racine Megacycle Club, c/o American Red Cross—Lakeshore Counties, 4521 Taylor Avenue, Racine WI 53405.

For more information, contact David Voss WB9USI, President, Racine Megacycle Club, 3333 Standish Lane, Racine WI 53405.

WAPAKONETA OH

The Reservoir Amateur Radio Association will operate K8QYL from 1300Z July 17 to 0400Z July 18 and again from 1300Z to 1900Z, July 18, from the birthplace of Neil Armstrong, the first man on the moon. Frequencies: phone—3940, 7260, 14285, 21360, and 28590, plus or minus QRM; CW—50 kHz up from the bottom of the band at the beginning of the odd hours. Check-ins invited on K8QYL/R (147.93/147.33). Certificate for QSL and SASE to: K8QYL, PO Box 268, Ceilna OH 45822.

TOM SAWYER DAYS

The Hannibal Amateur Radio Club, Inc., will issue a second annual special certificate from the National Tom Sawyer Days celebration in Mark Twain's boyhood home town, Hannibal, Missouri, on July 3-4, 1982. Hours: 1500-2100 UTC both days. Frequencies: phone—7.245, 14.290, 21.400, and 28.700; CW—7.125 and 21.125 MHz. The club will also be observing our 50th anniversary. Help us celebrate! To receive the certificate, send a large (8"×10") SASE and your personal QSL card confirming the contact to the Hannibal Amateur Radio Club, Inc., WØKEM, 2108 Orchard Avenue, Hannibal MO 63401.

BONFIELD IL

Commemorative amateur radio station K9JLK will be operating from the Bonfield, Illinois centennial celebration from 1300Z, July 4, 1982, through July 5. Operating frequencies will be 223.50, 144.250 (SSB), 146.520 (FM), 50.115, 28.600, 21.400, 14.325, 7.275, and 3.8-3.9. For QSL, send an SASE to Jerry Whalen WB9WOC, RR 2, Kankakee IL 60901.

WINONA MN

The Winona (MN) ARC will operate WBØNIU on July 3 to commemorate the 125th anniversary of the signing of the charter of the city of Winona. Winona is a river town in SE MN. The station will operate from 1500Z to 2100Z on 7.245, 14.290, 21.365, and 28.650 MHz. A special QSL for working this station will be available by SASE to Erik W. Brom WBØNIU, 3655 6th St., Winona, MN 55987. Other area stations will also be using these cards.

CELINA OH

The Reservoir Amateur Radio Association will operate W8DN from 1300Z to 1800Z, July 24, from the courthouse lawn during the Celina Lake Festival. Frequencies: phone—3940, 7260, 14285, 21360, 28590, plus or minus QRM. Check-ins are invited on WB8FNB/R on 146.01/146.61. Certificate for QSL and SASE to W8DN, PO Box 268, Celina OH 45822.

LETTERS

KB7NW A WINNER

I would like you to know that the article "Pacific Odyssey" by KB7NW was one of the best I have read in a long time. I thought the way it was organized and presented was topnotch, as was the use of photographs to supplement the excellent story line. I could almost feel I was there!

If you give awards for well-presented articles, J.D. Binders' "Pacific Odyssey" to Kingman and Palmyra sure get my vote!

This article is a credit to your magazine.

Homer Lasitter W6QX
La Jolla CA

We're glad you liked "Pacific Odyssey," Homer. And thanks for writing. Not only will the author enjoy your comments, the 73 staff appreciates the feedback. We encourage readers to let us know when they particularly like (or dislike) something in 73.—N8RK.

NO NUKES—I

I am a firm believer in our First Amendment rights, but I take issue with the basic premise of the May, *73*, article, "Surviving the Unthinkable." Yes, I agree that hams have a responsibility to be prepared for emergencies, but nuclear war IS unthinkable. There would be NO survivors. Preparing for a nuclear holocaust assumes there must be one, and that attitude just might help it happen. Hams should not give in—we must fight for our right to a life of peace.

David Stoft WD6DXX
Spokane WA

NO NUKES—II

I am upset by the "Surviving the Unthinkable" article in your May, 1982, issue, for several reasons. A sense of practicality plus the firm grasp on Murphy's Law which most amateurs have should reveal the weaknesses of the FEMA claims for how we shall evacuate. Missiles take only 30 minutes to arrive, and it will take far longer for all those in target areas to depart. To hope for any better circumstances is to hope that one's new antenna installation is going to go in without a hitch. Wishful thinking will not hack it.

True, amateurs can help in almost any emergency, but I feel that all amateurs should be burning the airwaves *now* to try to talk to anyone anywhere on the planet to forward the goal of preventing "the unthinkable." To cheerfully accept ten million deaths is insanity, no matter what the format!

I sense that this is another "Gee, gosh, we can be so helpful" article. I do not want to be in the position of trying to provide emergency service to what would be left. I would rather work now at some other solution to the problem than get first-hand experience on how Murphy would operate with nuclear weapons as tools of his "whatever can go wrong, will" policy.

Amateurs have a unique ability to speak to peoples of other countries. Let's use that ability to forward efforts to prevent a nuclear conflict, rather than become another vulture watching over a possibly dying America as a part of this government's new Civil Defense push.

BASH REHASH

Concerning the ongoing Dick Bash story, I'd like to add another log to the fire.

When's the last time you sat back in your favorite chair with a copy of *QST*'s Q & A manual? Unless you're sitting on a bed of nails with five kids screaming around you and the TV set too loud, within a few minutes after opening the front cover, you'll be checking the insides of your eyelids for holes. In short, it's more boring than a monotonous voice telling you last week's news.

The questions in that venerable manual are not quite the same as found on the FCC tests, but then again, if you look closely, they're not all that much different, either. The tricky part is trying to wade through what is termed an answer without having to reread it many times. By then, your attention and patience are wearing thin. After a few pages of this you begin to wonder if it's worth it. Those of stout heart and strong desire may make it just a bit further, but eventually the book is closed and gathers dust. The *Ameco Study Guide* is not quite as bad as it lays out the explanation without so much fairy dust sprinkled on it. If you haven't had the time to look over one of Dick Bash's books, he does give the test question and the test answer, but it doesn't just stop there. It explains why that is the correct answer and does it with enough literary flair to keep your interest to the point of making a more lasting impression.

For several years in the Army, I taught basic electricity and aircraft electrical systems to servicemen who not only didn't want to be there, but some of them shouldn't have even been there to begin with. Vietnam caused some barrel scraping near the end. How do you teach people like that? You create an atmosphere or situation that captures their interest. It wasn't easy and most instructors didn't even try, but when you succeeded you knew it and the students

knew it, too. I was also partly responsible for writing tests and lesson plans. My approach was somewhat similar to Dick's although greatly restricted due to bureaucratic regimentation.

Have you ever met Dick Bash? He's outgoing and congenial but a bit of a maverick, like most people who create or lead. He saw a weakness in the self-tutorial method of teaching a complex subject that was sorely lacking in instructional material that filtered out the black boxes, witches, and demons. There are those in this world who consider electronics as "black magic" and some of them are hams. Basic electricity, if taught properly, can be interesting and informative. If college courses are offered for electronics, how does the average person expect to learn it without some help?

Letters to editors are strange things. This is my first and probably last one. Every subscriber gets to read the editorial—which is really only one man's opinion—and the mass is left to draw its own conclusions but based only on the editorialized facts. The editor may consider it his prerogative to tell it the way he sees it, and who's to dispute it? I feel you were wrong to so vehemently condemn Dick Bash as you did and not give everyone the facts of what the book is really like. I've met Bash class graduates and find them no different from hams I met 10 or 15 years ago. We need to increase and strengthen our numbers and I don't feel one bit like we're compromising ourselves with Dick's books.

I can almost understand *QST* not wanting to run his ads. After all, a "non profit" organization in the publishing business with a corner on most of the "instructional material" has to protect its own interests. Doesn't it? What all this boils down to is this: Whether you consider the Dick Bash books unethical or not, they get the job done of informing and teaching. Even my wife learned enough to evoke a response of, "So that's how it works!" I'm not going to fault Dick's system one bit because it works. What I do fault is your remarks of "poison" and "being insidious" without ever telling what the books are like and letting people draw their own conclusions. I would expect that of a rag like the *National Enquirer*, but not from *73 Magazine*.

Fred Palmer WA5WZD
Corinth TX

Have I met Bash? Heck, Dick worked for us here for a while. He drove us crazy and we gave up trying to harness him. We parted good friends and I think stay that way. Dick knows what I think of his "system" and why.

The Bash approach does give some slight attention to explanations, but the brunt of his books is to present, word for word, the questions you are going to face... and their answers. The one-day intensives are designed to fill your short-term memory with the questions and answers, not long-term real understanding of electronics and radio. If you are unable to take the FCC test the next day after an intensive by Bash, you can be in deep trouble.

One of the more serious disasters of our whole educational process has to do with the continued use of short-term memory for the passing of tests instead of getting the information into the long-term memory. This is why so many students have little recollection of a course once they have passed it. This was my major gripe with college, where the emphasis was on read-and-take-a-quiz, with little effort to discuss the material and thus give it a chance to be understood and filed away in more permanent memory.

The Navy, on the other hand, had a fantastic course in electronics, where they taught theory and then immediately took you into a lab to work with that theory and thus grow to really understand it. In classes, we discussed the theory until we were able to think in electronic terms. If I'm able to get a college started, it is going to teach the students to think, not memorize. They are going to learn about electronics and then work with it. They will learn about communications and then learn to design, build, and service equipment. They will learn computer design... and repairs. They will learn to write programs and fix 'em.

It may be that amateur radio has so fallen apart under the pressures to let in one more friend or wife that it no longer is even considered important for hams to understand radio. If so, we should formally agree with this and throw away our charter, section 97, and put amateur radio and CB together into one service, being honest about our motives.

Fred, when I suggest that hams get mad about this and rush to their neighborhood ham store and rip Bash's cheat books to shreds, I know... as do you, if you think about it instead of reacting... that what will happen is a rush to buy these short cuts to getting a ticket. They do work. It is now possible to get a ham ticket without really knowing a damned thing about electronics or radio. People with a knack for the code can learn it enough to pass the test in about one hour. That's how long it took me to get to 5-wpm solid copy right from not knowing a single character.

If it's easy ham tickets you want, Fred, you've got 'em now. But I don't see that bringing in many hams. Hell, we can't even give ham tickets away these days. Now, I may be wrong about wanting hams to clean up the act... to get our clubs to start teaching the fundamentals of theory and making sure that newcomers qualify. Most of my mail says I have a lot of hams backing me, but there are opponents such as you.

Perhaps we are still being too strict in our tests. One could certainly make a case for the amateur tests being biased so that they exclude blacks, women, Chinese, Latin-Americans, and other such groups. Perhaps it is time for a move toward affirmative action and an open-door policy for these under-represented groups. Should we start seeing how simple we can make the procedure in order to give these minorities (and the female majority) their "rights"?—Wayne.

NO MISTEAK HERE

This letter is in reference to FCC spokesman Vernon Wilson's denial of misspellings on FCC code tapes (page 121, *73*, May, 1982).

Over the last few years I have taken one General class test and two Extra class tests (one failed because of nerves and pressures and one passed with 100% a month later). I found these tests to be difficult. However, there were no misspelled words, irregularities, or even sneaky tricks. I even had Springfield on one (spelled correctly). Interestingly, one fellow told me after the test that he had copied Springvale; another had copied Springdale.

Under the extreme pressure we hams generate within ourselves at test time, I believe it is quite possible to sincerely, but incorrectly, copy "mistakes" that simply are not there.

Lincoln Thorner KS2H
New York NY

KS2H's letter is like several others we have received. No one has come forward with documented evidence of a misspelling on the FCC code exams.—N8RK.

BRAINS NOT FISTS

I have here in front of me the March issue of *73 Magazine*, but what I want to talk about is not how much I like it but your stand concerning the requirement for the Morse-code test.

There should be no question but that in this day and age of space exploration and digital electronics, this requirement is pathetically antiquated and comparable to requiring Greyhound drivers to know how to handle a Conestoga wagon. It serves no purpose other than to keep away from amateur radio technically competent people who have neither the patience nor the time to waste in learning a skill that has no place in state-of-the-art electronics.

All of the surveys that showed "overwhelming opposition" to a no-code license have been performed with no objectivity and a lot of bias in a group of individuals who had a vested interest in the outcome. Nobody should be a part of, or a judge in, a contest of any kind who thinks: "What? A no-code license? Over my dead body! Let them sweat it out as I did!" You don't have to be endowed with divinatory powers to know beforehand the outcome of such a survey. In other words, newcomers not welcome!

Keep up the good work and be sure that once again we will see in the future who was right. What we need today is brain, not fist! Your suggestion to use technical knowledge as a filter, instead of Morse-code skill, does make a lot of sense.

Oh, by the way, let me tell you that I am not a frustrated would-

be ham who flunked the code test. Many years ago, more than I care to remember, I had to get a commercial second-class radio operator's license (including Morse at 20 wpm), and to this day I fail to see what good can come to amateur radio by turning the code skill into a fetish.

It is about time that some common sense is written into these regulations.

Paulo G. Lefevre

Carcavelos, Portugal

Olé.—Wayne.

HORSERADISH DISPLAY

I've been fascinated by QSL cards since I was an SWL in the early 1950s. A QSL is a special thing—representative of the individual, locale, and country of origin. I am quite aware of the expense involved, be it the simplest "Quick Print Shop" shot of a hand drawing or the elaborate five-run or color photographic rendition.

The thing that moved me to write this letter is the volume of cards seen since become a DX QSL manager (CE5BYY). Gentlemen—the ladies are now left out, they do it right—the blotter paper and repetitiously inane renderings passing this way don't even rate a shoe box as a repository. As a person driving up in an unwashed, beat-up automobile makes a lasting first impression, so do your cards.

It pains me to see that cards from the South Pacific that ten short years ago had swallowtail butterflies, birds of paradise, and outrigger canoes now look like the cards of members of the Southern California DX Club. How many cards can a person with DXCC, WAZ, and God-knows-what-all possibly send? Economy seems to rule, however, and I would offer the following comments.

1. Lack of return postage is a paramount issue as it makes the card expense critical.

2. The card's free, the freight ain't.

3. If you care and really have had at least one original thought in your life, consider the fact your card represents *you*, so do it cute, professionally, or at least in good taste and design.

If you're tired of seeing your country QSL display looking like horseradish and mustard, the solution really rests with you and the merchants of mediocrity who simplify the continuation of the problem. The DX is really waiting for you to get your act together.

Terry F. Staudt WØWUZ
Evergreen CO

Readers who don't like horseradish are encouraged to submit a QSL card to 73's monthly contest. You will find details with this month's winner.—N8RK.

DX FOR THE BLIND

Two years after losing my sight from detached retinas, I obtained my Novice class license. Six months later, I achieved General class status and have been a DXer ever since. Two common problems for the blind DXer are the inability to obtain current DX information and the difficulty of filling out DX cards.

I am writing this letter to inform blind DXers of a new and exciting service. The Braille DX Service provides: (1) a monthly cassette recording of current DX activity and expeditions, as well as important QSL information, and featuring the Kansas DX Association monthly newsletter, (2) a current DXCC countries list in Braille or on cassette tape, including regular up-to-date prefix changes, and (3) a personal QSL manager for outgoing cards. Volunteers fill out the blind DXer's QSL cards, and log information is passed, either by on-the-air schedules or simply by mailing the information direct to the volunteer. Log information can be recorded on cassette tape and mailed to the volunteer.

Membership is simply a one-time $2.00 donation to help purchase blank cassette tapes for the monthly newsletter. The Kansas DX Association has demonstrated their interest in this program by providing a cassette recording of the monthly newsletter and volunteer QSL managers for the blind DXer.

Lakewood CO

3 CHEERS FOR MFJ

I want you to know about an experience I had with one of your advertisers. Two years ago at the Atlanta Hamfest I purchased an MFJ-962 antenna tuner. Well, as you might know, I probably loaded it wrong and blew a small coil in the swr bridge circuit. I called them on their WATS line, and it was not until later that I read down the page a bit and saw that I had called the sales number and not the parts and service department. A very pleasant YL answered and, not understanding what I wanted to order, she connected me to an OM by the name of Stan. I explained to Stan that I had blown the coil, that the unit was out of warranty, and that I wanted to order another. Well, a strange thing happened for these times, as Stan refused to sell me the coil; instead, he insisted that I give him my name and address and he would get one out to me in the mail. . . at *no charge*! Now that is what I call darn good business PR.

It was not so much the cost (or in this case, non-cost) as it was the pleasant manner in which this was handled, and I would appreciate it if you would let your readers know about one of the "good guys"—MFJ Enterprises of Mississippi State, Mississippi.

HAM PEACE CORPS

In your *73* issue of November, 1981, I saw your editorial about South Africa and would like to record my disapproval of your visit to the Republic of South Africa.

South Africa is the only remaining country which violates human rights on the basis of race (skin pigmentation). This violation is perpetual and cannot be transcended (because you cannot change your color) and is grossly unfair to its people and the people of the world (because such ideas might spread out of South Africa to the rest of the world again). Therefore, it is necessary to fight such an unfair system by all means, including withholding technology, sports contacts, amateur radio contacts, etc.

Why? Because the racist minority in power (which does *not* include all South African whites) can use such technology to oppress the majority and international sports and cultural contacts to win international acceptance and legitimacy. Building up communication technology through amateur radio is one such example—communication technology can be used to spread ideas of apartheid and for police and military purposes.

You might say, sure, South Africa violates human rights, but what about other dictatorial regimes in Africa/South America/Asia? There, oppression is through ideology (belief systems) or money (class background of a person), etc., and boycott action against them is valid and is practiced, e.g., against Chile, Poland, etc. The only similar case is the caste system, as it is practiced in the feudal and backward areas of India—where you are born into a caste and are discriminated against.

As a citizen of a multi-racial democracy (the same as in your case) where people of various races (Caucasian, Mongolian, and Negroid) live in harmony, settle, and marry across regions and are guaranteed the same constitutional rights, I think it is our duty to discourage contacts with South Africa.

Right now, the Republic of South Africa is involved in a PR campaign (albeit the organization of such a campaign may well be loose) and is trying to get scientists, scholars, and sportsmen to visit them (e.g., UK cricket players, Taiwanese scholars, etc.). Clever as they are, they sent Dr. Christian Barnard (the famous heart surgeon and a believer in racism) to India, knowing that he would be the least objectionable here.

I respect *73* for its boldness (in criticism of regulatory bodies), its presentation (which is lucid and interesting), and its keeping abreast of new technology, and this is the very first time I feel the urge to express my disapproval. I hope that you will take it in a constructive spirit and respond to my arguments.

Gopal Kamat VU2JE
Bombay, India

Well, Kamat, just in case there are some readers who agree with your thinking, it might be prudent to answer your criticisms. Let's go back a few years to the time when the US was involved with Vietnam. Recall with me, if you will, that my country was being severely criticized by much of the world. Many people were busy not visiting the US be-

cause it was involved in that unpopular war.

Possibly, Kamat, you were not a reader of 73 during those years. If you had been you would know that there were a number of Americans who were not in favor of the war. Some reacted by being completely negative about it...just get out and leave 'em alone. Others recognized the problems involved, but felt that there was more than one way to respond. Indeed, I made a trip around the world and talked with hams in many countries about the situation. As a result, I developed a plan which I felt was far better than fighting. I distilled the ideas I ran into in Yugoslavia, Thailand, Singapore, and New Caledonia as I talked with hams in these countries.

My plan seemed relatively simple, workable, and most likely to result in avoiding further bloodshed. I am convinced that if the US had followed it that a unified Vietnam would be free of communism...as would Laos and Cambodia. I wrote of my plan in 73 and got hundreds of letters supporting it. I also sent it to Congress, but as far as I know not one copy ever got through the assistants. I failed ...but at least I tried.

Now, about South Africa. Sure, many people are at odds with the South African government. But does that mean that we have to hate South Africans? What possible benefit is that to anyone? I went to South Africa to visit the hams and computer fanatics, not the government. As a matter of fact, I don't think I met anyone from the government.

The people that I did meet and talk with are as helpless about the policies of their government as I was about mine. They, sadly, have far less freedom to speak up in criticism...but then there are very few countries which are as permissive as the US. And remember, please, that there are some government agencies in the US which will not permit open criticism. Our country is good in many ways, but it is far from free as yet.

May I contrast your negative attitude with my positive one. You advocate not visiting countries of which you disapprove. I advocate visiting them and advocating changes to them which will improve the situation. Indeed, while I was in South Africa I went on television during prime time and said flat out that it was time for them to consider making some moves to change their basic policies. I am told that over a million blacks and whites saw my broadcast.

I think I got their attention when I put it this way...I explained that there are about 59 countries in Africa and that approximately 58 of these hate South Africa. I suggested that perhaps it was time to start doing something to counter this ...and I had a positive suggestion, not a negative one.

As I pointed out, we are entering an electronic age. Computers and telecommunications are inseparable with the future. I also pointed out that unless South Africa did something... and quickly...the country would be passed by in technology. To keep up with the need for people to invent, build, operate, and service the technology of the future, they are in need of tens of thousands of technicians and engineers.

The only reasonable source of this many technical people will be for South Africa to make it a policy to introduce amateur radio and computer clubs in their high schools. They will have to get teenagers interested in technical careers.

Okay. The next step is an obvious one...the need for technical colleges to bring these interested teenagers up to the state-of-the-art in electronics, communications, and computers. This can be done either the expensive way...by the government paying for it...or it can be done by getting private industry to pick up most of the tab. I suggested they consider my plan for opening a college which is integrated with several local electronics businesses. In this way, the students would get the best of the formal technical education...and the practical professional experience of working with a business firm.

Further, I proposed that they include plenty of business courses so that the students would be well rounded in both technical matters and business. I suggested that they teach advertising, writing, speaking, finance, hiring, personnel management, purchasing, and so on.

The income from working with the on-campus firms would keep the end cost of the education low and within the reach of most middle-income families.

Then, once this idea had sunk in, I proposed what my interviewer called the Electronic Peace Corps. This was a plan to bring in worthy students from the other African counties for a free education in this new type of school. The cost would be low and the students, once they returned to their native countries, would soon rise to the top by virtue of their education and experience.

The people in the other African countries realize that they have no opportunity for a good education unless they leave their country. At present, the only sources for a free education lie in Moscow and Havana. These are not very attractive alternatives. Further, the people in these countries realize that they are on a downward spiral, something which only an infusion of educated people can change.

The courses in South Africa would not, at first, be very popular because of the hatred. But something as valuable as that for nothing might overcome all sorts of emotional blocks. South Africa would have to see that the black students were treated fairly and given the best of educations. I think the floodgates would open and eager students would come in from all over Africa.

It will take a long time to change Africa...but isn't it time to get started? There are tremendous resources in Africa ...with plenty of country for farms, millions of educable people, and nowhere to go but up. Yes, there are tremendous obstacles. I've been there and seen them. I've talked about them with ham friends in many of the African countries. We're looking at several generations before things are really changed.

But with educated entrepreneurs in more and more African countries it could be possible to stop the destruction of these countries by their despot leaders and to start working for their eventual strength.

Isn't it better to visit a country and make a try at doing something to help change things? The thousands of people who have not visited South Africa have done nothing. It may be that my voice has been completely lost...but I did try.—Wayne.

REVIEW

ICOM IC-4A 440-MHZ HT

I recently purchased an Icom IC-4A 440-MHz hand-held FM transceiver because I wanted to get on the FM portion of the 3/4-meter band in the most cost-effective manner possible. I wanted to move up from the Motorola T-44, which lacks frequency stability and is quite large and heavy. I believe that I made a very good decision and if you'll read on, I'll be glad to tell you why.

First, I decided that my next rig would be new. With a unit straight from the factory, you get some kind of a warranty—at least saying that it will work right from the start. (Everything that I ever bought used always had something wrong with it.) Usually one faces a minor thing such as a noisy volume control or a worn-out switch. But if it is an intermittent problem that wants to be hard to trace down, may God help you! Also, when people sell their old gear they seem to want almost what they paid for it way back when. This is good salesmanship, I suppose, but I'd rather spend the extra bucks for state-of-the-art and a warranty.

No Crystals

Second, I decided that the rig would be synthesized. Activity on 440 is growing as more and more of the two-meter-FM crowd are getting one of the current crop of 70-cm FM hand-held units (Icom IC-4A, Yaesu FT-708R, Tempo S-4, Santec ST-440/up). Therefore, more repeaters are bound to appear.

Transmit and receive crystals of the high-accuracy (HA) vari-

Photo A. The IC–4A hand-held 440-MHz FM transceiver. (Photo by Michael D. Landis)

ety go for just over thirteen dollars a copy (anything less just doesn't make it). After a one- to two-week wait, the crystals arrive, and after installing them in the radio, you get to adjust those tiny trimmer capacitors until you are exactly on frequency. Also, the price of twenty crystals, as an example (ten for transmit and ten for receive), times thirteen dollars each comes to $260, which is about what I paid for my IC-4A.

The IC-4A offers 2000 possible channels—the top 10 MHz of the 420-to-450-MHz band, in 5-kHz steps. The thumbwheel switches select the frequency in 1-MHz, 100-kHz, and 10-kHz steps, with the 5-kHz select switch just to the right of the thumbwheel switches. (The switch at the extreme right is not used by Icom—it is there for you to wire up a switchable tone encoder.)

The antenna connector is a BNC type, and below it are external microphone and speaker jacks. To the right of the antenna connector is an LED which lights during transmit. It also serves as a battery indicator; if it goes out while you are squeezing the push-to-talk switch on the left side of the radio, your battery has just died. (You can, as soon as you notice the LED go out, immediately unkey, then key up again and say rapidly, "This is [your callsign]—clear," if this makes you feel better. You may even get through. If not, the next person in line will probably sign you out.)

On the back of the radio are three slide switches. The rf power switch, which is the top one, selects between .15 Watts out in the low position and 1.5 Watts out in the high position. In the low-power position, you draw only 43% of the current that you do in the high position, so you can transmit about twice as long. But remember that you're putting out only one-tenth the power. I do not consider this to be a good enough trade to warrant the use of the low-power position unless I am within spitting range of a repeater.

Below the power-select switch is a duplex/simplex select switch, and below that is a +5-MHz/−5-MHz transmit offset switch. Don't ask me why Icom does not use a single three-position switch that has 5 down, simplex, and 5 up on it. My IC-4A does not have an out-of-band transmit-inhibit circuit in it since the HT will transmit

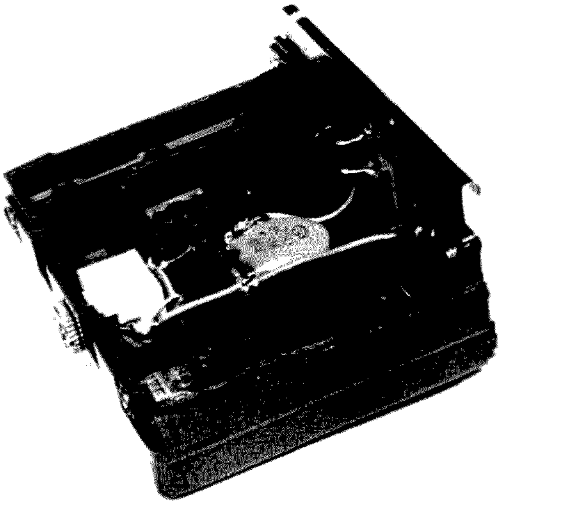

Photo B. The regulator circuit in the BP-4 case. (Photo by Michael D. Landis)

from 435.000 MHz to 454.995 MHz when in the duplex mode.

The microphone is located on the front of the radio case to the bottom right of the speaker, just above the word "microphone" that is molded onto the case. I was so used to those CB-type hand-helds where the speaker is used as the microphone that it took me a while to realize that I was directing my voice into the wrong place. Talk into the lower-right corner of the speaker where there is a little rectangular slot cut into the case, and you will get full audio quality!

The unit comes in a grey plastic case, lacks the bells and whistles that inhabit the fronts of other brands of HTs, and doesn't have as much shiny metal. To me, it looks more like a policeman's HT than a ham's playtoy.

Along with the radio you get the rubberized flexible antenna, a BP-3 battery pack and a wall charger for it, a metal belt clip and two screws with which to attach it to the radio, a hand strap (which I never use), an earphone (which I never use), and one each submini plug and mini plug for the external mike and speaker jacks. You also get an instruction manual which gives a good general idea of what is going on, and two separate sheets which are quite detailed schematic and circuit board layouts. The size and appearance of the rig is identical to the IC-2A/AT, and except for antennas, they use the same accessories.

The radio will not scan unless you want to wear out your fingers on the thumbwheel switches, so you must own a programmable scanner or know the frequencies you will be using. Otherwise, you may need to get one

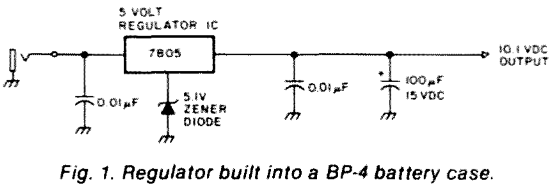

Fig. 1. Regulator built into a BP-4 battery case.

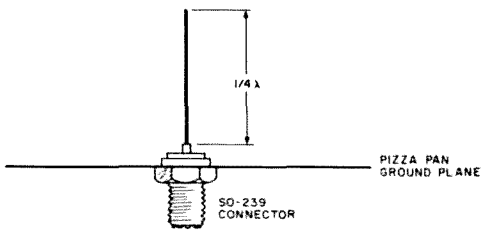

Fig. 2. An improvised quarter-wave ground-plane antenna.

of the band-scanning rigs instead of this one.

For some serious rag-chewing with this rig, you need either a basketful of batteries or an ac-operated power supply. I have built a regulator circuit into a BP-4 battery pack case which allows me to use the car battery (via a cigarette lighter power adapter and a miniature plug) or my unregulated 13.8-V-dc power supply at home. The schematic for the regulator is shown in Fig. 1, and Photo B is a close-up of the finished product. (If you don't like my way, you can look up WB3JJF's article in the February, 1981, issue of *Ham Radio*.)

When I'm at home, I use an improvised quarter-wave groundplane antenna that works quite a bit better than the rubberized whip antenna. It consists of a pizza pan (for the ground plane) with a hole in the center to hold an SO-239 jack. (See Fig. 2.) I soldered a stiff copper wire to the top of the jack. A PL-259 plug with RG-58/U or RG-8/U cable is screwed onto the connector, and the length of the copper wire whip is trimmed to one-quarter wavelength or for lowest standing-wave ratio at your favorite frequency.

Unfortunately, I don't have a lot of sophisticated test gear, but I can tell you that .3 microvolts of signal will definitely quiet all the rushing noise in my receiver. The power with a fresh battery is somewhat higher than that stated in the manual, and most amazing of all (to me) is that all channels are stable, with very little frequency drift.

I got my IC-4A for just under $260 from my local ham radio store in December, 1981, and for another twenty dollars or so, I could have gotten the touchtone™ pad version.

I want to thank WA8JJI for the improved antenna idea, my sister Frances for the permanent loan of two of her pizza pans, and also Mike Landis, who took the pictures.

Now I can hardly wait for Icom to come out with its 23-cm (1215-1300-MHz) band HT. For more information, contact *Icom America, 2112 116th Ave. NE, Bellevue WA 98004.*

Ferndale MI

IC-25A 2M FM MOBILE RIG

It may be a mystery to most of us how the manufacturer managed to stuff so many components, operating features, and good ideas into so small a package, but it is no mystery that the trend in ham gear today is toward the small. In this ham's opinion, with reference to medium power (25-W) VHF ham gear, the apogee of miniature electronics is reached by the Icom IC-25A two-meter FM mobile rig.

Features

The rig measures a mere 5" by 2" by 7" and weighs in at a paltry 3.3 pounds. Within these lilliputian dimensions, Icom has crammed 48 transistors, 5 FETs, 19 ICs, 91 diodes, and a 4-bit microprocessor to keep track of the lot. The result of this shoehorning is a feature-packed mobile radio that offers the user: 25-W/1-W power outputs, scanning of five memory and two vfo frequencies, full or programmed band scan, programmable splits for non-standard repeaters, dual-speed vfo tuning in 5-kHz or 15-kHz steps, seven-segment S/rf LED bar display, priority channel function, normal/reverse function for monitoring repeater inputs or working inverse splits, and, most important, two fully-independent vfo's. And all this from the front panel!

Should you require more options, you need only open the top cover to gain access to: a scan speed control, a scan-stop timing control, a scan-stop timer switch, and a scan-stop function switch. The last allows the operator to choose either busy or open channels for scan-stop.

By comparison, the rear panel is simple. Here, arrayed around a massive heat sink of the SC1019 power amplifier, is a power-connection cable, an SO-239 antenna connector, and an external speaker jack (4 to 8 Ohms).

The IC-25A is designed to run off a 13.8-V-dc source, and no provisions are made for reversing the negative ground configuration of the supply. The manufacturer claims that the unit draws 400 mA in squelched receive and 600 mA with full audio output of 2 Watts. In the transmit mode, the rig draws 1.3 A at one Watt out and a healthy 4.8 A for the full 25-W output. Icom suggests that a 6-A supply be used in base-station applications.

Design

Electrically, the IC-25A exemplifies solid design practice. The transmitter uses a double-balanced mixer and variance-reactance frequency modulation to generate 16F3 output. A high-impedance dynamic mike with built-in touchtone™ pad and preamplifier is provided as standard equipment. The receiver employs a double-conversion superhet scheme (i-fs at 16.9 MHz and 455 kHz) as well as a MOSFET rf amplifier. A double-balanced mixer, two monolithic crystal filters, and several ceramic filters are provided to improve selectivity.

The most unusual aspect of the IC-25A's design is the dual vfo system. The rig's heredity can be seen clearly from its frequency-control system, and anyone who has ever operated an Icom 701, 720, 730, etc., will feel quite at home with the IC-25A. At the heart of the frequency-control system is a digital phase-locked loop (PLL) circuit that generates 40-MHz and 122-MHz signals.

A rotary encoder connected directly to the main tuning dial generates clock pulses for up/down frequency selection. A 4-bit-wide CPU chip running under the control of Icom firmware provides the smarts. The result in an extremely flexible frequency-control system that allows for continuous tuning in 5-kHz or 15-kHz steps, depending on which of the two vfo's is chosen.

About the only feature left out of the IC-25A's frequency selection system is the ability to memorize offsets. As a result, operator intervention is required if operation is desired on a memory frequency with a new split.

Performance

The bottom line for any piece of mobile gear is its performance on the open road. After commuting with the IC-25A for more than three months, I can say honestly that it is one of the friendliest mobile rigs I have ever used. Of paramount importance in a rig this size is front-panel layout. With 13 controls jammed into an 11-square-inch area, the ergonomics of the layout had better be good.

Vfo and memory-selection channel switches are located toward the driver, on the left side of the front panel. The large main tuning knob also is skewed to the left. Volume/on-off and squelch/high-low power controls are placed adjacent to one another and, immediately above them, three push switches provide easy (yet isolated) access to scan-width control, simplex/duplex control, and Nor/Rev function.

The one inconvenient placement on the front panel is the proximity of the memory-write switch and the scan-stop switch. A problem often occurs when, in an effort to initiate scanning, an operator inadvertently depresses the memory-write switch. When this happens, an erroneous frequency (whatever happens to be in the vfo at the time) will be written into one of the memory channels. The problem is further compounded by the identical feel of the switches. (Mike-scan control is an option, however.)

Another front-panel shortcoming involves the display. Aside from the normal visibility problems inherent with red displays operating in bright sunlight, the IC-25A display is difficult to read because it uses an LED instead of a full 7-segment digit in the 5-kHz position. As a result, it can be difficult to discern whether the frequency is 7.37 or 7.375. There seems to be room on the front panel for a full-size 4-digit display, and the rig certainly would benefit from the addition of a real digit in the 5-kHz position.

Used in conjunction with a 1/4-wave whip, the IC-25A was able to access any repeater it heard. In fact, it often heard too much. My unit displayed adjacent-channel interference on strong signals (40-60 dB) 15 kHz away from the center of the passband, resulting in cross-modulation of the incoming audio. The problem seemed more acute on the high side of the passband, indicating a slight receiver alignment irregularity. In any case, the problem, though annoying, was apparent only on the strongest of signals.

With any radio of this complexity and compactness, documentation is crucial. Icom has done a laudable job in this area, and its efforts are by no means limited to the 34-page owner's manual. An 11" by 16" schematic is included as well as life-size component overlays for each PC board. When used in conjunction with the comprehensive theory-of-operation section of the manual, graphics like these could get hams once more into

troubleshooting and even repairing their own gear.

The IC-25A is an impressive package of performance and features at a very competitive price. (The list price is $349.) Its small size will make it attractive to owners of today's gas-efficient micro-cars, and as an added benefit, when installed in-dash like a normal car radio, the rig is relatively immune to theft. If you want big radio functions in a small package, Icom's new IC-25A is worth your consideration.

For more information, contact *Icom America, 2112 116th Ave. NE, Bellevue WA 98004.*

Heath VL-1180 All-Mode VHF Amplifier. The amplifier board is on the left, T-R board on the right.

HEATHKIT MODEL VL-1180 ALL-MODE VHF AMPLIFIER

New England is a land of hills and valleys; it's challenging country for 2-meter mobile operation. I discovered just how challenging shortly after installing a 10-Watt rig in my car. Delighted at being able to hear my buddies chatting on a popular repeater some 20 miles distant, I attempted to join the conversation. "Sorry old man, you're not quite making the machine." How humiliating!

An amplifier was definitely in order. And since my 2-meter rig is an all-mode radio, I wanted an amp suitable for SSB and CW, as well as FM. The Heathkit VL-1180 All-Mode VHF Amplifier had just been announced. As a long-time Heathkit builder, I couldn't resist.

Description

The VL-1180 is a linear amplifier covering the 144-148-MHz range. It is designed for use with exciters providing between 1 and 10 Watts of drive. A Motorola MRF-247 transistor is used as the final, and the nominal output is 75 Watts with 10 Watts input. Insertion loss is 0.6 dB. The amplifier features a self-contained transmit-receive (T-R) relay which is keyed either by a push-to-talk line from the exciter or by the rf sensing circuit built into the VL-1180. The amplifier operates on 11.5-15 V dc and draws 11 Amps at 75 Watts output. Standby current is a mere 3 mA.

The VL-1180 measures 2-1/2 × 4-5/8 × 10-1/2 inches and weighs 3-1/2 pounds. A power switch is the only control provided. The power leads and T-R switching line (if used) enter the amplifier by way of a three-conductor Molex® plug.

Except for connectors and the power switch, all components in the VL-1180 mount on a pair of double-sided printed circuit boards. The larger of the two holds the amplifier circuitry. A smaller board contains T-R switching. Assembling the amplifier took five easy evenings. While no insurmountable problems were encountered, the amplifier board was a challenge in one respect.

In order to ensure a good connection between the ground foils on the top and bottom of the board, you are instructed to install and solder in place 47 tiny rivets. While tedious, this is a simple procedure. The rub comes when, in six places, you are required to solder a metal-cased mica capacitor to the circuit board, squarely on top of a rivet head. Due to the presence of the rivet, it is difficult to get the "continuous bonding" between capacitor and PC foil called for in the manual. A simple relocation of the six offending rivet holes would cure a minor but aggravating problem. As with all Heathkits, the best course is to follow the instructions as closely as possible.

With the VL-1180 temporarily installed in my car, alignment was a breeze, requiring about 15 minutes from start to finish. Tune-up is accomplished with a minimum of equipment: a 2-meter exciter, an swr meter, and a dummy load. Heath deserves a round of applause for designing an amplifier that is so easy to align; they even supply the necessary alignment tools. When aligned at 146 MHz, the output with 10-W drive was at least 80 W across the entire 2-meter band. One Watt of drive produced 9 Watts out. Input swr was less than 1.5:1 throughout the band.

The additional power provided by the VL-1180 has made all the difference in my FM mobile operations. No more humiliation when attempting to join the fun on the repeater! The amplifier has proven itself on SSB as well. I have spent many a Sunday afternoon atop our local drive-up mountain talking to the SSB boys on 144.2 MHz, using a portable five-element beam.

After more than six months of heavy use, the VL-1180 continues to perform well. Output power is unchanged from the original 80 Watts. The low standby current drain means that the amplifier can be left turned on at all times, unless the car isn't going to be driven for weeks on end.

Summary

Heath has done a nice job in creating an all-mode 2-meter linear kit that goes together without much difficulty and doesn't require a sophisticated test bench to align. A solution to the rivet problem should be considered, however, even if it's only to acknowledge it in the manual. Ideally, Heath should switch to a circuit board with plated-through holes.

The bottom line is, that despite minor construction difficulties, my VL-1180 worked the first time out and has worked ever since. It's hard to ask more from any piece of equipment. The VL-1180 is priced at $137.95 from *Heath Company, Benton Harbor MI 49022.* Reader Service number 475.

PHASE IIIB LAUNCH DELAYED

We'll all have a bit more time to prepare for Phase III satellite activity. The European Space Agency (ESA) has announced a delay of at least two months in the flight that is scheduled to carry AMSAT's Phase IIIB satellite. At best, the launch will now occur in late September; it was originally set for July.

The problem is not with the Phase IIIB satellite or the Ariane launch vehicle, but with the design of the satellite that is to be the main payload on several Ariane launches. A similar satellite, MARECS-A, was launched in December and has developed some unexpected problems. Until the causes and cures for the problems can be determined, the scheduling of the Phase IIIB launch will remain uncertain.

TEN-TEC RIG

At the Dayton Hamvention in late April, Ten-Tec displayed a prototype of a rig designed to ease the average amateur into Phase III satellite communications, using the Mode B (435-144 MHz) transponder. The new unit contains a 10-W, 435-MHz CW/SSB transmitter and a 2-to-10-meter receive converter. Assuming you already have 10-meter receiving capability, you need only add antennas for 435 and 144 MHz to complete your Phase III satellite station. Ten-Tec doesn't plan to release the rig until Phase IIIB is safely aloft, i.e., sometime this fall.

ORBITAL CALENDARS

Project OSCAR, a California-based group of amateur satellite enthusiasts, has produced a comprehensive calendar of orbital predictions covering OSCAR 8 and all six Soviet RS satellites. This volume gives the time and longitude of the northbound equatorial crossing for each orbit of each satellite from May 1 through December 31, 1982. It's a must for satellite chasers. The calendar is available for an $8.75 donation. Your check or money order payable to Project OSCAR, Inc., should be mailed to POB 1136, Los Altos CA 94022. The price includes postage.

Thanks to *AMSAT Satellite Report* for some of the preceding information.—WB8BTH.

COMMUNICATIONS DIVISION

(We Speak Your Language.)

Backed by over 54 years of experience, Harvey continues to offer the broadest selection and finest service available for the amateur radio community. This experience has taught us that the ham needs special treatment and that is why Harvey has established a special division dedicated to the needs of the U.S. and foreign ham alike.

One thing is for certain. A ham will never get the run around from Harvey. If we don't have something in stock, we say so and will order it for you—or—tell you where to get it. However, we are sincerely dedicated to the ham community and, as a result, our expansive inventory means that, more than likely, we will have what you are looking for *in stock*.

SOCIAL EVENTS

from page 78

City Park Avenue, New Orleans LA 70119. (504)-483-4115.

FLAGSTAFF AZ
JUL 30-AUG 1

The Amateur Radio Council of Arizona will hold its 32nd annual hamfest from July 30 through August 1, 1982, at the Fort Tuthill Fairgrounds, just a few miles south of I-40, Flagstaff AZ. There will be thousands of dollars in prizes, improved XYL activities, a swapfest, a transmitter hunt, speakers, forums, awards, exhibits, and entertainment on Friday and Saturday nights. Overnight camping facilities will be available. Talk-in on 147.870/146.270. For further information, contact Wm. Oliver Grieve W7WGW, 4301 N. 31st Avenue, Phoenix AZ 85017, or call (602)-246-0200.

KINGSFORD MI
JUL 31-AUG 1

The Mich-A-Con ARC will hold the 34th annual UP Hamfest on Saturday, July 31, and Sunday, August 1, 1982, at the Dickinson County Armory on M-95, Kingsford MI. Tickets are $2.50 at the door (no advance sales) and registration will begin at 9:00 am on both days. There will be prizes, family activities, and a Saturday night banquet. Advance banquet reservations are needed since seating is limited. Plenty of free parking will be available. Talk-in on 146.25/.85 and .3922. For further information, write UPHAMFEST-82, 105 East Breitung Avenue, Kingsford MI 49801.

ANGOLA IN
AUG 1

The Steuben County Radio Amateurs will hold the 24th annual FM Picnic and Hamfest on Sunday, August 1, 1982, at Crooked Lake, Angola IN. Admission is $2.50. There will be prizes, picnic-style BBQ chicken, inside tables for exhibitors and vendors, and overnight camping. (A fee will be charged by county park.) Talk-in on 146.52 and 147.81/.21.

PITTSBURGH PA
AUG 1

The 45th annual South Hills Brass Pounders and Modulators Hamfest will be held on August 1, 1982, from 10:00 am to 4:00 pm, at South Campus, Community College of Allegheny County, Pittsburgh PA. Admission is $2.00 or 3 for $5.00. There will be computer, OSCAR, and ATV demonstrations, as well as a flea market. Talk-in on 146.13/.73 and 146.52. For further information, contact Andrew L. Pato WA3PBD, 1433 Schauffler Drive, West Homestead PA 15120.

BELVIDERE IL
AUG 1

The Big Thunder ARC will hold its annual hamfest on Sunday, August 1, 1982, at the Boone County Fairgrounds, Route 76, Belvidere IL. Admission is $2.00 in advance and $2.50 at the gate. A fee will be charged for 8-foot tables and there will be indoor space available in the exhibit building, as well as outdoor space in swappers' row. Sellers will be able to set up Saturday evening or at 7:00 am on Sunday. Features will include door prizes, a main prize, food, and refreshments. Camping will be available on Saturday evening (there will be a charge for electricity). Talk-in on 146.52 and 147.975/147.375. For further information or tickets, send an SASE to Jim Grimsby, 418 Beacon Drive, Belvidere IL 61008.

LEVELLAND TX
AUG 1

The Hockley County Amateur Radio Club and the Northwest Texas Emergency Net will hold their 17th annual picnic and swapfest on Sunday, August 1, 1982, beginning at 6:00 am at the city park in Levelland TX. This event is for the entire family. Bring your own picnic basket for lunch at 12:30. A two-meter FM transceiver is the grand prize. A $3.00 registration is requested but not required. There will be swapping all day, with tables provided. Talk-in on .28/.88.

GLEN MI
AUG 1

The Black River Amateur Radio Club will hold the 29th annual Southwestern Michigan VHF Picnic on Sunday, August 1, 1982, at the West Side County Park near Glen MI. (Take exit 30 from I-196 and follow the signs.) There will be swimming, a playground, a small flea market, and door prizes. There is no food available at the park, so bring your own picnic basket. Registration is $1.00. For additional information, contact Ed Alderman KI8Z, RR #2, Box 44, Lawrence MI 49064.

POMONA CA
AUG 7

The Tri-County Amateur Radio Association will hold its annual hamfest/picnic on Saturday, August 7, 1982, from 7:00 am to 1:00 pm, at the Los Angeles County Fairgrounds, Pomona CA. All buyers, sellers, and computer buffs are welcome. There will be prizes, exhibits, and refreshments. Talk-in on 146.025/.625. For more information, write to TCARA Hamfest Chairman W6ELZ, PO Box 142, Pomona CA 91769.

JACKSONVILLE FL
AUG 7-8

The Greater Jacksonville Hamfest Association will hold the annual Jacksonville Hamfest and Northern Florida ARRL Convention on August 7-8, 1982, at the Orange Park Kennel Club, located near the intersection of I-295 and US 17 just south of Jacksonville. Advance registration is $3.50 and is available from Robert J. Cutting W2KGI, 1249 Cape Charles Avenue, Atlantic Beach FL 32233. Registration at the door is $4.00. The FCC will administer amateur and commercial radio operator exams on Friday, August 6th, at the hamfest site. Those wishing to take the exams should apply to the Atlanta FCC office as soon as possible. Swap tables are $12.00 per table for both days (no one-day tables) and table reservations, as well as advance registrations, are available from Andy Burton NX4G, 5101 Younis Road, Jacksonville FL 32218. A full slate of programs is scheduled, along with meetings of statewide and regional nets and organizations, plus competitions including a rabbit hunt and pileup contest. The headquarters hotel is the Best Western First National Inn just across from the hamfest. Special rates may be obtained by writing to Jim Canfield KD4CG, 996 Dostie Circle, Orange Park FL 32073. Talk-in on 146.16/.76 and 146.07/.67.

SAUK RAPIDS MN
AUG 8

The St. Cloud Radio Club will hold its annual hamfest on Sunday, August 8, 1982, from 8:30 am to 4:00 pm, at the Sauk Rapids Municipal Park, Sauk Rapids MN. Talk-in on 146.34/.94. For more information, contact Mike Lynch, 2115-1st Street, St. Cloud MN 56301, or call (612)-251-2297.

MONTGOMERYVILLE PA
AUG 8

The Mid-Atlantic Amateur Radio Club announces its annual J. B. M. Hamfest to be held on Sunday, August 8, 1982, from 9:00 am to 4:00 pm, rain or shine. Tailgate setup begins at 8:00 am. Located at the Route 309 Drive-In Theater, 1/4 mile north of Route 63, Montgomeryville, PA (6 miles north of the Fort Washington interchange of the Pennsylvania Turnpike). Admission: $2.50, with $1.00 additional for each tailgate space. Non-licensed XYLs and children admitted free. Ample parking, refreshments, raffles, door prizes, and more. Talk-in on WB3JOE/R (147.66/.06) or 146.52 simplex. For further information, write the club, PO Box 352, Villanova PA 19085.

TACOMA WA
AUG 14-15

The Radio Club of Tacoma will hold Hamfair 82 on August 14-15, 1982, at the Pacific Lutheran University campus, Tacoma WA. Registration is $5.00 and dinner is $7.50. Activities will include technical seminars, a flea market, commercial booths, an ARRL meeting, a repeater forum, a VHF tweak and tune clinic, prizes, raffles, and a loggers' breakfast. Talk-in on 147.88/.28. For more information, contact Grace Teitzel AD7S, 701 So. 120th, Tacoma WA 98444, or phone (206)-564-8347.

WILMINGTON DE
AUG 15

The seventh annual New Delmarva Hamfest will be held on Sunday, August 15, 1982, from 8:00 am to 4:00 pm at Gloryland Park, Bear DE (5 miles south of Wilmington). Admission is $2.25 in advance, $2.75 at the gate. Tailgating is $3.50. Limited tables will be available under the pavilion, but bring your own to be sure. Food and drinks will be available. First prize is an Atari® Home Video Game System. Talk-in on .52 and .13/.53. For more information and a map, send an SASE to Stephen Momot K3HBP, 14 Balsam Road, Wilmington DE 19804. For advance tickets, make checks payable to Delmarva Hamfest, Inc.

TIOGA COUNTY PA
AUG 21

The Tioga County PA ARC 6th Annual Amateur Radio Hamfest will be held on Saturday, August 21, 1982, from 0800 to 1600 at a new location at Island Park, just off US Rte. 15, Blossburg PA. There will be a flea market, food, free camping, an auction, an H/T door prize, etc. Talk-in on .19/.79 and .52. For more information or advance tickets, write Tioga Co. ARC, PO Box 56, Mansfield PA 16933, or contact Paul Sando KC2AZ, 606 Reynolds Street, Elmira NY 14904 on .19/.79 or .96/.36.

MARYSVILLE OH
AUG 21-22

The Union County Amateur Radio Club will hold the Marysville Hamfest on Saturday afternoon and all day Sunday, August 21-22, 1982, at the fairground in Marysville (near Columbus) OH. Admission is $2.00 in advance or $3.00 at the gate. Flea market space is $1.00. Food, beverages, and free overnight camping, movies, and popcorn will be available. Featured on Saturday night will be a free square dance (with a live band) followed by a big country breakfast available all night. Door prizes, ladies' programs, and ARRL, FCC, and MARS meetings will be featured on Sunday. Talk-in on 146.52 and 147.99/.39. For additional information, write UCARC, 13613 US 36, Marysville OH 43040, or call (513)-644-0468.

ST. CHARLES IL
AUG 22

The Fox River Radio League will host the Illinois State ARRL Convention in conjunction with its annual hamfest, both to be held on August 22, 1982, from 8:00 am to 4:00 pm, at the Kane County Fairgrounds, St. Charles IL. Tickets are $2.00 in advance and $3.00 at the gate. For advance tickets, send an SASE to J. Dubeck KA9HQY, 1312 Bluebell Lane, Batavia IL 60510. There will be commercial exhibits, a flea market, contests, demonstrations, forums, prizes, and hot food. Talk-in on 146.94. Exhibitors, dealers, and vendors should contact G. R. Isely WD9GIG, 736 Fellows Street, St. Charles IL 60174.

WENTZVILLE MO
AUG 22

The St. Charles Amateur Radio Club, Inc., will hold Hamfest 82 on August 22, 1982, at the Wentzville Community Center, Wentzville MO. Tickets in advance are $1.00 each or 4 for $3.00; at the door, they are $1.50 each or 4 for $5.00. Admission is $1.00 per car. There will be prizes, contests, a flea market, food, and air conditioned exhibitions buildings. For tickets, motel and camping information, prize lists, dealer reservations, etc., write SCARC Hamfest 82, c/o Mike McCrann WD0GSY, 25 Elm Street, St. Peters MO 63376.

SEWELL NJ
AUG 29

The Gloucester County Amateur Radio Club will hold its fourth annual GCARC Ham/Compfest on Sunday August 29, 1982, from 8:00 am to 3:00 pm at the Gloucester County College, Tanyard Road, Sewell NJ. Tickets are $2.00 in advance and $2.50 at the door. The tailgaters' and dealers' charge is $6.00 and includes one free admission. Doors will open at 7:00 am for setup. There will be speakers, seminars, contests, FCC exams, and prizes, including a Radio Shack TRS-80 computer and a Yaesu FT-208R. Talk-in on 146.52 and 147.78/.18. For more information, contact GCARC Hamfest Committee, PO Box 370, Pitman NJ 08017, or phone (609)-456-0500 or (609)-338-4841 (days) or (609)-629-2064 (evenings).

BUTLER PA
SEP 12

The Butler County Amateur Radio Association will hold its annual hamfest on Sunday, September 12, 1982, from 9:00 am to 4:00 pm, at the Butler Farmshow Grounds at Roe Airport, Butler PA. Fly-in at Butler Farmshow Airport. Admission is a $1.00 donation and children under 12 will be admitted free. Overnight campers are welcome and food and refreshments will be available. There will be an indoor flea market (vendor space will be $3.00 per 8-foot table), a free outside flea market, free parking (including for the handicapped), and prizes, including a Kenwood TS-830S HF transceiver. Talk-in on 147.96/.36, .52, and 147.84/.24. For additional information, contact Leighton Fennell, Crestmont Drive, RD 6, Butler PA 16001, or phone (412)-586-9822.

DEALER DIRECTORY

Phoenix AZ

The Southwest's most progressive communications company stocking Kenwood, Icom, Yaesu, MFJ, B&W, Astron, Larsen, Cushcraft, Hy-Gain, Bearcat, and more. Would like to serve you! **Power Communications Corp., 1640 West Camelback Rd., Phoenix AZ 85015, 241-Watt.**

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Diego CA

We buy and sell Surplus Army Navy Electronics, also Terminated Material. What do you want to sell? Write for catalogue. **Electronictown, Inc., 440-7th Avenue, PO Box 2048, San Diego CA 92112, 232-9379.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Smyrna GA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. **Britt's Two-Way Radio, 2506 N. Atlanta Rd., Smyrna GA 30080, 432-8006.**

Preston ID

Ross WB7BYZ has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 478003, 238-1456.**

Littleton MA

The ham store of N.E. you can rely on. Kenwood, ICOM, Wilson, Yaesu, DenTron, KLM amps, B&W switches & wattmeters. Whistler radar detectors, Bearcat, Regency, antennas by Larsen, Wilson, Hustler, GAM. **TEL-COM Inc. Communications & Electronics, 675 Great Rd., Rt. 119, Littleton MA 01460, 486-3040.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, DenTron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.**

Hudson NH

New England's Distributor and Authorized Service Center for all Major Amateur Lines. **Tufts Radio Electronics, Inc., 61 Lowell Road, Hudson NH 03051, 883-5005.**

Somerset NJ

New Jersey's only factory-authorized ICOM and YAESU distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.**

Buffalo NY
WESTERN NEW YORK

Niagara Frontier's only full stocking Amateur dealer. Also Shortwave, CB, Scanners, Marine, Commercial. Operating displays featuring Kenwood and others. Towers, Antennas, Sales and Service. **DX Communications, 3214 Transit Road, West Seneca NY, 668-8873.**

Syracuse-Central NY

HAM-BONE RADIO SAVES US LOT OF $$$ on all Icom, Ten-Tec, HyGain & Kantronics Gear. Fast, Dependable Service Before & After the Sale! Service is Our Main Business! Need Cash—Ham-Bone will sell your gear for 10% commission. 3206 Erie Blvd. E., Syracuse NY 13214, 446-2266.

Philadelphia PA/ Camden NJ

Waveguide & Coaxial Microwave Components & Equipment. Laboratory Grade Test Instruments, Power Supplies, Buy, Sell & Trade all popular makes—HP, GR, FXR, ESI, Sorensen, Singer, etc. **Lectronic Research Labs, 1423 Ferry Ave., Camden NJ 08104, 541-4200.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Syracuse-Rome-Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 337-0203.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Bend OR

Satellite TV. Known brands. Call today for more information and inquire about our dealer program. **WESPERCOM, P.O. Box 7226, Bend OR 97708, 389-0996.**

Scranton PA

ICOM, Bird, Cushcraft, Beckman, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, CDE, AEA, Vibroplex, Ham-Key, CES, Amphenol, Sony, Fanon/Courier, B&W, Ameco, Shure. **LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.**

Dallas TX

Dealer in Used Computer Hardware & Electronic Parts. Special on Daisy Wheel Printers. Xerox Word Processing Equipment, Dual Card Printers and Display Systems. Catalog $1.00. **Rondure Company (The Computer Room) Dept. 73, 2522 Butler St., Dallas TX 75235, 630-4621.**

San Antonio TX

Amateur, Commercial 2-way. Selling Antenna Specialists, Avanti, Azden, Bird, Hy-Gain, Standard, Vibroplex, Midland, Henry, Cushcraft, Dielectric, Hustler, ICOM, MFJ, Nye, Shure, Cubic, Tempo, Ten-Tec and others. **Appliance & Equipment Co., Inc. 2317 Vance Jackson Road, San Antonio TX 78213, 938-3350.**

Vienna VA

The Washington metropolitan area's leading supplier of the latest in Amateur Radio and Test Equipment. On your next trip to the Nation's Capital, stop by and see us. **Electronic Equipment Bank, Inc., 516 Mill St. N.E., Vienna VA 22180, 938-3350.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the Sept. '82 issue must be in our hands by July 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

THE WORLD'S FAIR—KNOXVILLE

Yes, there is a ham exhibit at the new World's Fair. The local hams got together and managed to get some space in the Knoxville exhibit for the station. It's a good looking exhibit, packed with Ten-Tec gear for the most part. That's not too surprising since Ten-Tec's plant is just a few miles from Knoxville.

The fair isn't large by World's Fair standards. I've only seen a few such fairs, so perhaps I was expecting too much. I am old enough to have spent a good deal of time wandering the New York fair in 1938, watching the early television programs being produced. They had iconoscope cameras in those days, so the lights had to be fierce compared with the later developed image orthocons, which were far more sensitive (and expensive).

They had a lot of entertainment exhibits at that fair. I didn't see much of that at Knoxville. Here the exhibits are almost entirely international and national, with little from our major industrial corporations.

At the Montreal fair, there was a good deal of entertainment, but the lines were so long to watch it that many were discouraged. I know I had to miss most of the highly touted shows because I didn't have a day apiece to devote to line standing. Fortunately, most of the ones that I had to miss at Montreal turned up when San Antonio had their World's Fair, so I eventually saw them.

I'm beginning to recognize that a successful fair means hot weather and long, long lines. I think the line for the Chinese exhibit is almost the length of the whole fair! It reminded me of an illustration by Ripley for an item which said that there were so many Chinese that a column of them four wide could parade by night and day forever, with the newly born keeping up with the pace of the line. The line at the fair seemed endless. Most of the more interesting exhibits had lines, but none compared with the Chinese.

It appears that Knoxville has gotten a bum rap from some of the media. I was there in late May and found little problem in getting hotel accommodations. Even when I went on Sunday to the fair, I was able to park within one block of the fair gate. They have parking lots all around the outskirts of town where you can leave your car and be commuted by a bus.

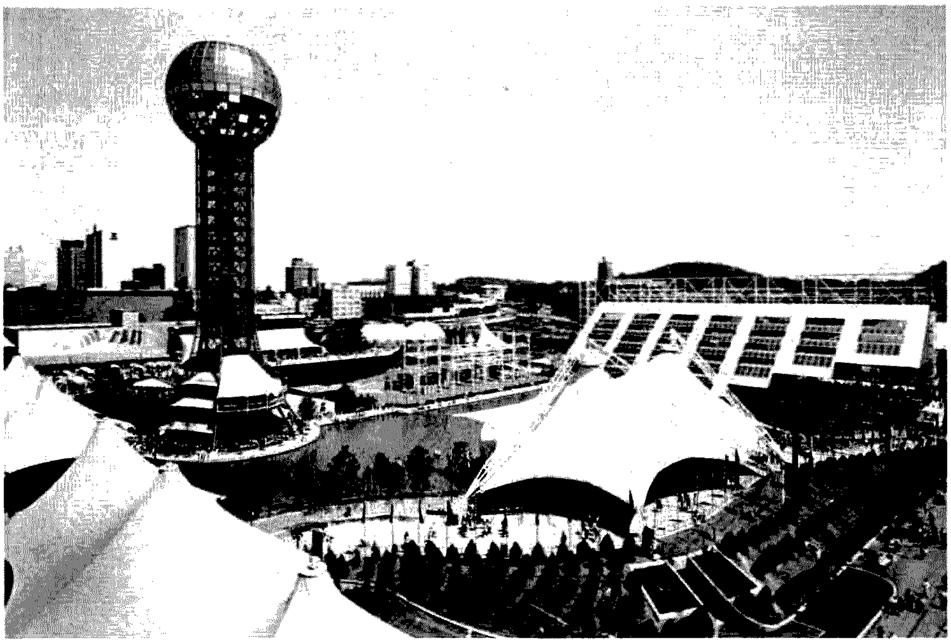
Of course, my favorite subject is food. That was one of my big memories of the New York fair of '38. Montreal was a bust, with most of the food stands selling only buffalo burgers—which are okay, but not exciting.

At San Antonio, I had a great time eating. They had all sorts of fast food services. Knoxville has done the same. They have one of the widest varieties of food of any fair yet. Have you ever seen a cobbler stand? Yep, a choice of apple, cherry, blueberry, or mixed fruit cobbler, with or without soft ice cream. You could also get Belgian waffles, nice and fresh and crisp, with either whipped cream or soft ice cream.

There are plenty of repeaters around Knoxville, so if you decide to drive to the fair you won't have any problem getting talked in. I called in on 146.73 and got route instructions—first to the Knoxville hamfest, then to the fair. No problem getting help.

If you're within driving distance of Knoxville, I'd say it's worth your while to plan on getting down there (or up) this summer. Be sure to check in at the ham exhibit and log in. If you flash your ham license, they'll let you sit down and do some contest-type operating. It seems that World's Fair stations are reasonably rare, so there are pileups for everyone. It's a lot easier than getting down to Swaziland or something. And you can get a taste of quite a bunch of foreign countries by visiting their exhibits.

Speaking of the Knoxville hamfest, while I didn't see anyone there from *Ham Radio* magazine, I did catch a glimpse



Three of the landmark structures of The 1982 World's Fair in Knoxville, Tennessee, form around the three-acre Waters of the World Lake. At left is the Sunsphere, 266 feet high and the "theme structure" of the exposition. The five-level sphere, encased in glass made of 24-karat gold dust, houses a restaurant and two cocktail lounges and observation areas. In the right foreground is the 1,500-seat Tennessee State Amphitheatre. The United States pavilion (at far right) features "talk-back computers," a "national energy debate" utilizing television screens and a new IMAX film, to be shown on a screen seven stories high and 90 feet wide. Downtown Knoxville forms the background at left. (Photo by Mike DuBose)

of one of the *CQ* chaps. Funny thing, even though this was an official ARRL hamfest, I didn't see any of their officials. Hmmm. Maybe I missed 'em.

The people at Ten-Tec, In addition to supporting the ham exhibit at the World's Fair, also had the most elaborate exhibit at the hamfest. I don't know how they get any work done!

The ham station at the fair was not of enough importance for the FCC to manage a special events call, but the Knoxville chaps were very resourceful. A local club had the call WA4KFS, so they "borrowed" the call for the fair...it representing the Knoxville Fair Station.

I sat down for a few minutes to see how the station was working. Aiming the beam at Europe, I found a relatively clear spot (not bad for Sunday afternoon on 20m) and called CQ. Wouldn't you know that the chap who came back to my call lives a few miles from Peterborough and, when he found out who was operating, mentioned that he drives past my place every day going to work!

Having been on the ham tour to China a year ago, I wasn't ready to face the three-hour or more line to see their exhibit. Then I found out that our press passes not only got us in the fair free, but were also useful for going to the head of lines. Hmmm. It makes good sense since one of the things the fair needs most desperately is some good press. So Sherry and I ambled down to the China exhibit, flashed our press passes, and got right in.

Sherry was disappointed, I think. Sure enough, China had all their stuff there on exhibit... with a lot of the items for sale. But It was pretty much the same as we'd seen at the Canton Trade Fair. We did come close to buying one of their gorgeous rugs. Only the problems of shipping it home slowed us down In Canton...now we had no such excuse. The rugs are spectacular and quite reasonable in price. They're not as inexpensive as in China, of course, but they're still a bargain.

The exhibit was interesting, but would have been a bummer if we'd had to invest much line time. That's probably one of the drawbacks to being into travel.

The worst days as far as lines are concerned are Friday and Saturday. Thursday Is the lightest attendance day, with Sunday being second. That's Baptist country, remember, and Sunday is for church. The lines for food were small, if any. Sure, if you really *had* to have a hamburger and wanted it at 12:30, there was a line. But right next to that stand you could get something more interesting with no wait. The Hungarian ex-

Poor Man's Spectrum Analyzer

—another 73 breakthrough

Frank H. Perkins WB5IPM
Box 13642
Arlington TX 76013

Hams enjoy making all types of electrical measurements. In fact, it's one of our favorite pastimes and topics of conversation. Fortunately, good, low-cost oscilloscopes, DVMs, and other instruments are available to us for measuring voltage, current, power, swr, frequency, and so on.

There is one instrument, however, that has been beyond the reach of most of our budgets—the spectrum analyzer. Commercial versions of this useful rf instrument start at $2500, which is a little steep for most of us. It is possible for you to build a simple spectrum analyzer for about $150 that works with a low-cost oscilloscope. The analyzer can be used to check HF transmitting equipment, among other applications. Its use, theory of operation, and construction are discussed in this article.

Spectrum Analyzer Operation

A spectrum analyzer is a special receiver that allows you to view the frequency components of its input signal on an oscilloscope CRT. The spectrum analyzer repeatedly tunes across the frequency band you have chosen with its center-frequency and frequency-span controls. For example, if you set the center-frequency control for 20 MHz and adjust the frequency-span control for a tuning range from 10 MHz below to 10 MHz above the center frequency, the analyzer will repeatedly tune the 10-MHz-to-30-MHz band.

As the analyzer tunes from the low end to the high end of the band, it moves the CRT trace from left to right. The S-meter output from the analyzer moves the CRT trace upward from the bottom of the CRT screen according to signal strength. A spectrum analyzer display usually looks like a number of spikes. The farther to the right a signal (spike) appears on the CRT, the higher its frequency; the strength of the signal is indicated by its height. There usually appears to be some "grass" along the bottom of the CRT display. This is due to noise. You probably have seen spectrum analyzer displays in ham gear sales literature and some magazine articles.

To appreciate how useful a spectrum analyzer can be, let's first look at Photo B, an rf signal on a normal oscilloscope. To me it looks like a clean sine wave. What do you think?

Now let's look at Photo C, the same rf signal on our spectrum analyzer. The half-spike on the left is our zero-frequency reference. The next signal to the right, which is the tallest, is the fundamental component of our rf signal. The three signals to the right of the fundamental are the 2nd, 3rd, and 4th harmonics.

If the spectrum of our transceiver or linear amplifier output looked the same as this photo, we would not be complying with FCC Regulation 97.73, even though our fundamental signal was properly within an HF amateur band.

To understand what's wrong, compare the height of the 2nd harmonic signal to the fundamental. The second harmonic is about 2.6 CRT divisions shorter than the fundamental. With a 10-dB-per-division vertical calibration, the second harmonic is 26 dB below the fundamental.

FCC Regulation 97.73 re-

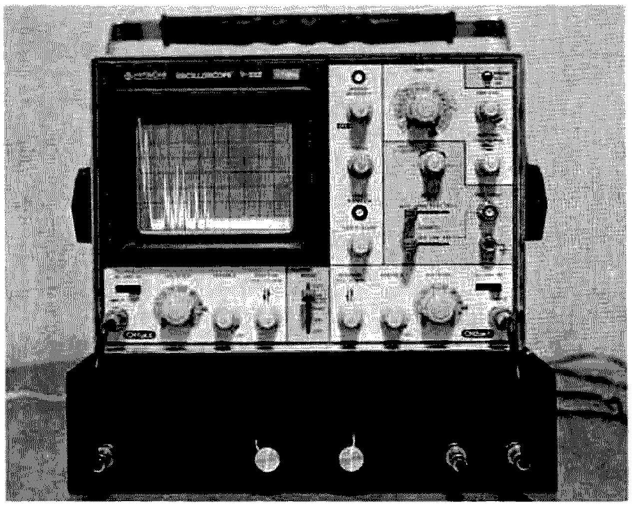

Photo A. High frequency spectrum analyzer covers 0 to 60 MHz.

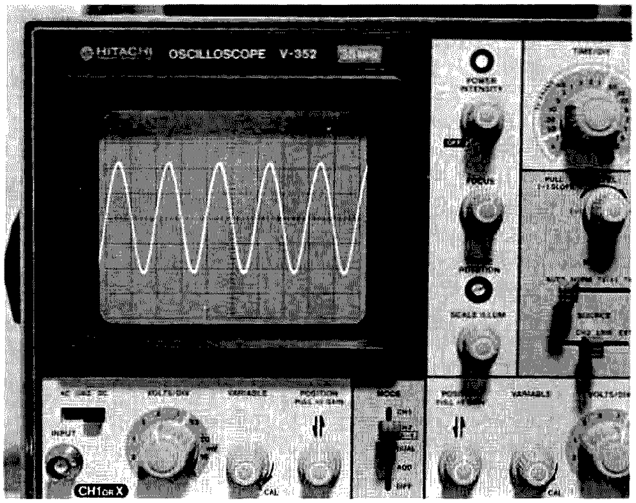

Photo B. Rf signal as viewed on an ordinary oscilloscope. Is this a clean signal?

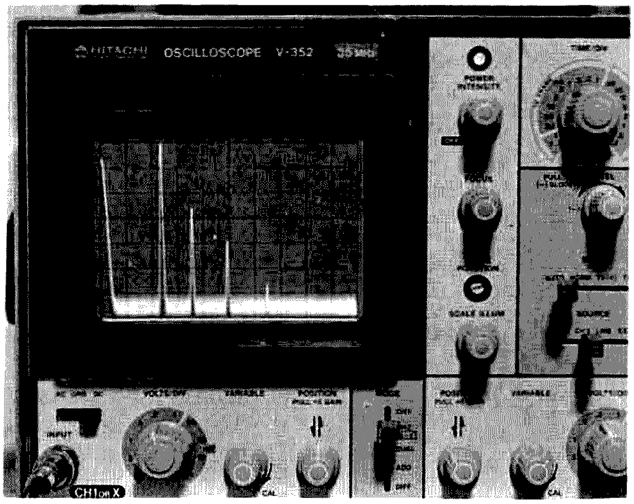

Photo C. Same rf signal on the spectrum analyzer. Second harmonic is only 26 dB below the fundamental. Don't put this signal on the air!

quires low-power transmitters up to 5 Watts to suppress all signal frequency components (spurs) outside the HF band of operation at least 30 dB below the fundamental. For a transmitter from 5 to 500 Watts, this figure is 40 dB. For a 1000-Watt transmitter or linear amplifier, the figure is 43 dB. Checking our photo again, we notice that the 3rd harmonic signal is about 39 dB below the fundamental. We're also going to have a problem with the 3rd harmonic if we are running 5 Watts or more power. The 4th harmonic is no problem since it's about 55 dB below the fundamental.

We can correct the problem by adding a filter between our transceiver or linear and the antenna. However, unless we are able to check the output spectrum of our transmitting equipment, we may never know we have a problem—until our neighbors start complaining or we get a "friendly advisory" from the local FCC monitoring station.

There are many uses for a spectrum analyzer besides monitoring transmitter outputs, but this use alone can make an HF spectrum analyzer construction project worthwhile. If you build one, you'll probably be the first on your block (or in your favorite net or club) to have one of your own!

Spectrum Analyzer Hookup

Fig. 1 shows how to hook up the high frequency spectrum analyzer for monitoring the output spectrum of a transmitter or linear amplifier. Remember, the analyzer is a receiver. It requires a very small sample of power for operation. This is done with an L-pad sampler. The sampler will not interfere with normal transmitting or transceiving operation. The output from the L-pad is further reduced with a step attenuator to match the full-scale input-power requirements of the analyzer (1/4 to 1/10 of a milliwatt). The spectrum is displayed on the oscilloscope being used with the spectrum analyzer.

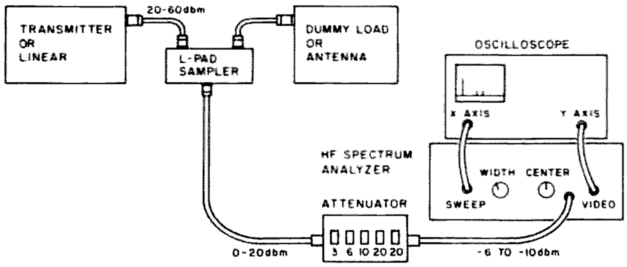
It is important to observe good safety practices when using the L-pad, attenuator, and spectrum analyzer. Be sure all station equipment, the L-pad, attenuator, analyzer, and oscilloscope cases are properly grounded. Use the proper L-pad for your power range. Double-check your hookup before applying power. If the output of a transmitter was directly connected to the analyzer by accident, it would instantly be damaged when the transmitter was keyed.

Overall Circuit Operation

Let's first discuss Fig. 2, the spectrum analyzer block diagram. We will then look at the circuits in each block in detail. Notice that the analyzer block diagram looks similar to that of a single-conversion superheterodyne receiver. The i-f frequency of the spectrum analyzer is 90 MHz.

The sampled input signal from the L-pad is adjusted to the proper power level with the step attenuator, as we discussed before. The signal is then taken through a low-pass filter with a 60-MHz cutoff frequency. The low-pass filter prevents 90-MHz signals from leaking into the analyzer and "confusing" it. The input is next mixed with the 90-MHz to 150-MHz voltage-controlled oscillator (vco) in the double-balanced mixer. The difference output from the mixer, which is the desired i-f signal, is then filtered by the 90-MHz bandpass filter. The bandpass filter provides the necessary selectivity for the spectrum analyzer. The 90-MHz signal from the bandpass filter is preamplified and applied to the log amplifier. The output of the log amplifier is logarithmic signal strength video for the oscilloscope vertical (Y) axis.

The voltage-controlled oscillator frequency is controlled by the sweep generator, which simultaneously controls the horizontal (or X axis) of the oscilloscope. Note that when the vco is



Note 1. **Never hook transmitter or linear directly to step attenuator or analyzer. Always use L-pad sampler of the proper power rating.**
Note 2. **Be sure transmitter, linear, L-pad, attenuator, analyzer, and scope are grounded.**

Fig. 1. Typical HF spectrum analyzer hookup.

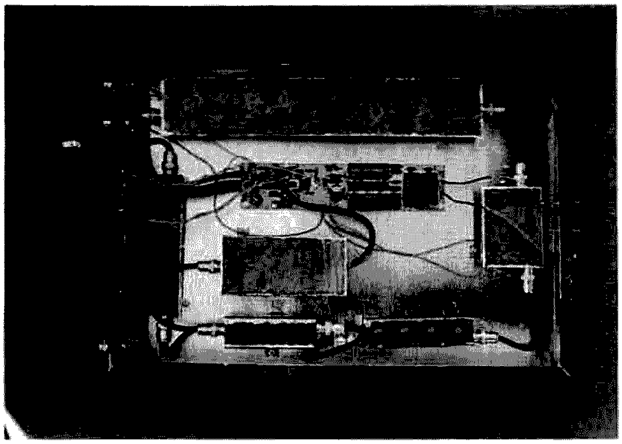


Photo D. Bottom view of spectrum analyzer chassis. Log amplifier is at the top. Power supply and sweep generator board is directly below the log amplifier. Vco is next. The mixer is directly below the vco. The mixer connects to the low-pass filter at the left. The bandpass filter is at the lower right. Preamplifier is on the middle right.

tuned to 90 MHz, the analyzer is tuned to zero MHz. When the vco is tuned to 120 MHz, the analyzer is tuned to 30 MHz. With the vco at 150 MHz, the analyzer is tuned to 60 MHz.

The tuning range of the analyzer is adjusted with the center-frequency and frequency-span controls on the sweep generator. The sweep generator automatically tunes the analyzer across its tuning range about 10 times each second. The sweep generator clamps or "shorts out" the video during the retrace between each sweep to avoid a confusing oscilloscope display. This eliminates the need for an oscilloscope with a Z-axis (blanking) input. The power supply provides +24 V dc, +12 V dc, and −6 V dc for the spectrum analyzer circuitry. The power supply operates from 12 V ac supplied by a wallplug transformer.

L-Pad

Fig. 3 shows the schematic of a 100-to-1000-Watt L-pad sampler, with alternate circuitry for a 10-to-100-Watt sampler, a 1-to-10-Watt sampler, and a 0.25-to-1-Watt sampler. Four pairs of 4.7k, 1-Watt resistors form the series element of the 100-to-1000-Watt sampler. A 51-Ohm, 1/2-Watt resistor forms the shunt element. The L-pad resistors are rated for continuous operation. A single hair-thin strand from an old "zip" cord provides some fusing protection in the event of a component failure or circuit fault. The series elements for the other power ratings are shown in Fig. 3.

0-to-59-dB Step Attenuator

Fig. 4 shows the step attenuator schematic. Five pi-style resistive attenuators are switched in or out as necessary to achieve the proper attenuation. Switches are double-pole, double-throw. Resistors may be 1/2 Watt or 1/4 Watt, although 1/4-Watt resistors are easier to work with. Note the shielding between sections. Resistors must be 5% tolerance. (The resistor values for each attenuator came from Reference 1.)

Low-Pass Filter, Mixer, and Vco

Fig. 5 shows the details of these circuits. The low-pass filter consists of three pi-sections, separated by shielding. The cutoff frequency of the filter is about 60 MHz. Three sections are used to give a high attenuation at the 90-MHz i-f frequency and above.

Each port of the double-balanced mixer is padded with 50-Ohm attenuators to

encourage good mixer performance (low mixer spurs) at the expense of extra conversion loss. Mini-Circuits SRA-1 and SBL-1 are good commercial mixers. It is quite possible to build a suitable double-balanced mixer from small ferrite toroids and hot carrier diodes, if you have trouble finding these commercial units. (Consult Reference 1 for details.)

The vco consists of an MRF901 Colpitts oscillator coupled to a wideband 2N5179 amplifier. The MRF901 was eventually chosen for the oscillator transistor because of its well-behaved phase-shift characteristics between 90 MHz and 150 MHz. The two MV109 hyper-abrupt Epicap diodes act as tuning capacitors and account for the oscillator's wide tuning range. A small pick-up loop near the oscillator coil provides an output for checking frequency and doing other tests. The oscillator is also lightly coupled to the 2N5179 vco amplifier. The output of this amplifier drives the local oscillator port of the mixer. A diode-capacitor rf detector provides a dc output for checking amplifier output power. The wideband amplifier design is based on data from Reference 1. The oscillator design is based on third-attempt desperation! Note the use of the feedthrough capacitors and shielding. These are as much a part of the circuit as the MRF901.

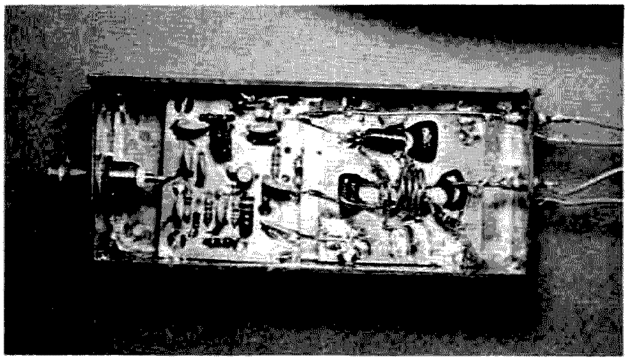

Photo E. Vco layout. Oscillator is near the feedthroughs.

Bandpass Filter

The bandpass filter is detailed in Fig. 6. It consists of four relatively small helical resonators. The input and output resonators are tap-coupled to the input and output connectors. The four resonators are aperture-coupled to each other. The two center resonators are slightly stagger-tuned to give the filter bandpass a sharp "nose." The 3-dB

bandwidth of the filter is about 220 kHz. Insertion loss is somewhat high, but is acceptable for this application.

Preamplifier and Log Amplifier

The schematics of the preamplifier and log amplifier are shown in Fig. 7. The preamplifier consists of two wideband 2N5179 amplifiers. The log amplifier consists of six tuned 90-MHz i-f stages. Each stage uses the friendly 40673 dual-gate FET. The input stage acts as a buffer amplifier. The next five stages form the logarithmic signal-strength video detector. The log amplifier may remind you of an i-f strip in an FM receiver. In fact, it uses the limiter principle in its operation.

Notice that each stage in the log amplifier has an rf detector across its output consisting of a 50-pF capacitor, a 1N914 diode, and a 10k resistor. The rf detector on the buffer stage is just a tuning aid. The outputs of the rf detectors on the 1st through 5th log amp stages are tied to a common 1k resistor (in parallel with a 150-pF capacitor). Because of its relatively low value, the detector outputs are more or less summed across the 1k resistor.

A small input signal is amplified by all five log amp stages. Only the 5th stage will develop enough signal to provide an output from its detector. As the input signal is made larger, the 4th stage detector also will begin contributing to the output. As the output is made still larger, the 5th stage will saturate or limit. From this point it will contribute no additional voltage across the 1k output resistor. At about this same signal level, the 3rd log amp stage will begin to contribute some output, and so on. Each log amp stage provides a gain of about 12 dB until it saturates. The gain of the i-f strip, from the 1k resistor's point of view, then drops 12 dB. It is this successive limiting and dropping off of i-f stages that creates the logarithmic video output characteristic. Note that when the 1st log amp stage saturates, the log amplifier reaches its full-scale output.

I was surprised how accurately the logarithmic amplifier does track a logarithmic curve. Using my commercial step attenuator as a reference, the calibration of my logarithmic amplifier was within 1 dB. The sensitive i-f system must be shielded to prevent interference from commercial FM stations.

Power Supply and Sweep Generator Circuits

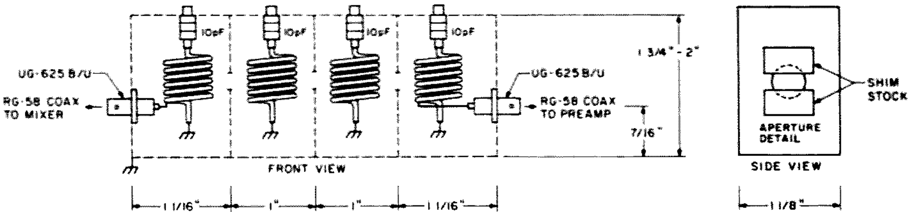
These circuits are shown in Fig. 8. The power supply is straightforward, providing +12 V dc, +24 V dc, and −6 V dc. Note the feedthrough capacitors used to filter out any rf picked up by the 12-V-ac power leads.

The heart of the sweep generator is the 555 IC timer. The two 2N2907s act as current sources. Each generates linear ramp voltages across 10-uF tantalum capacitors. The 555 synchronizes the ramps. The ramps are set at a 10-Hz-to-12-Hz repetition rate. One ramp is fed through a dc-restoring capacitor-diode clamp to the output connector for the oscilloscope horizontal (X) axis. The second ramp is fed to the 5k frequency-span potentiometer through an inverting operational amplifier buffer. The output from the frequency-span pot is summed with the output of the 5k center-frequency pot in the vco-tuning voltage amplifier. The output of this amplifier is fed to the vco-tuning voltage input.

When the ramps are reset by the 555, pin 3 of the 555 also trips the retrace VMOS clamp transistor through the retrace comparator amplifier. This shorts the logarithmic amplifier video output to ground during retrace. Otherwise, the video is fed to the output connector for the oscilloscope vertical (Y) axis. The 4th amplifier in the TL084C quad-operational-amplifier IC is used simply as a 6-V-dc reference by the other three amplifiers.

Shielded Enclosure Construction

All circuits in the high frequency spectrum analyzer except the sweep generator and the power supply must be installed in shielded enclosures. I built each enclosure for my analyzer using 1/16-inch, G-10 epoxy circuit board stock. Enclosure base plates are made from single-sided or double-sided stock. Double-sided stock must be used for the enclosure sides, ends, and partitions. (See Fig. 9 for construction details.)



Note 1. Coils are 6 turns of #12, 1/2" inside diameter, 5/8" long, taps at 1/4 turn.
Note 2. 10-pF piston trimmer, Sprague-Goodman GGP8R500 or equivalent; alternate, air-variable, Johnson 189-564-1.
Note 3. Filter box made from single- and double-sided G-10 circuit board plus copper shim stock.
Note 4. Filter box is 1-1/8" deep.
Note 5. Mount BNC connectors near front side.
Note 6. Coupling apertures are 3/8" x 3/16". Drill 3/8"-diameter holes in compartment wall pieces and then solder copper shim strips across tops and bottoms to narrow apertures.

Fig. 6. Bandpass filter.

Note the brass "cap strips." These provide a base for soldering on the thin copper (shim stock) enclosure tops. I use this method for mounting the tops so that they can be peeled back easily when I need to modify or repair circuitry. Use a 40-Watt soldering iron for soldering the enclosures together. Solder the tops on with a 25-Watt iron. Be sure the solder seams have no gaps.

Don't let the need for shielded enclosures discourage you. There are several easy, accurate ways to cut circuit board material. Beg, borrow, or buy a copy of *Printed Circuits Handbook* (Reference 4). This book does a good job of showing how to cut circuit board stock. Alternatively, make friends with a ham who owns or works at a commercial circuit board shop! Anyway, making shielded enclosures is easier than it first appears.

My original analyzer used quite a few BNC connectors. The number of connectors can be reduced by building the low-pass filter, mixer, and vco enclosures together on one base plate. Look at the schematic, Fig. 5, for shield partitioning details. Likewise, the preamplifier and log amplifier enclosures can be built together (Fig. 7). The bandpass filter should be built by itself, as should the attenuator. This arrangement allows the analyzer to be tuned up with very little test equipment.

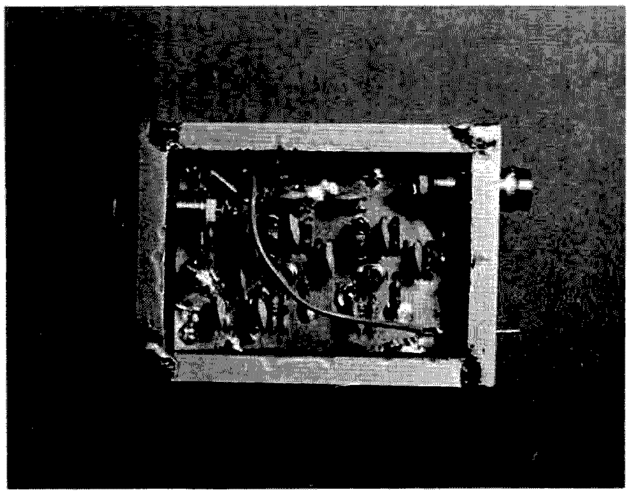


Photo G. Preamplifier layout. Note that the brass "cap strips" have been installed.

Circuit Board Layout and Construction

There are a lot of possible component substitutions for the spectrum analyzer. Some of the components you use in your analyzer will no doubt be different from the ones I used —at least in physical size. This makes standard circuit boards impractical. It is easy to lay out your circuitry for construction on single-sided circuit board stock. The copper is on the top side. It acts as a ground plane and helps stabilize the circuitry. All analyzer circuitry built in this manner was built on 1.8-inch-wide circuit board strips—lengths as needed. The low-pass filter, bandpass filter, and attenuator are built "in the air" inside their shielded enclosures. They don't need a circuit board.

Get some drafting vellum with a light blue, 1/10-inch grid on it. After you have all the parts for a circuit, you can begin developing its circuit board layout. After mulling over the schematic, lay the actual components on the grid paper and think through their interconnections. Juggle them as needed into a neat arrangement. Remember that all ground connections are going to be made on the top.

After you have the layout and interconnections visualized in an area, pick up each component and sketch in its outline on the vellum. Show its connection to other components (under the board) with dotted lines. You will be surprised how fast this goes. Remember to keep the input and output components of each rf stage separated. This is aided by using circuit board strips. Check the photos of my layout for ideas (minor circuit changes were made after some of the photos).

Once the layout is complete, tape it to your circuit board blank. Drill through the layout into the circuit board each place where a component or wire lead goes through the board. Use a #55 drill bit. After all holes are drilled, lightly countersink with a 1/8-inch drill bit all holes that are not going to be a ground connection. This keeps the leads going through these holes from shorting to the ground plane. Drill 1/8-inch holes in each corner of the board. 4-40 × 1/2-inch screws are put in these holes to act as legs for the board. Begin installing components. They are interconnected under the board by their leads and/or bus wire. Remember to keep connections as short as possible.

The vco oscillator circuit is built totally on top of the circuit board ground plane so that leads can be very short. Follow the layout in the photo carefully. The vco amplifier is built in the normal way.

I used brass tubes (bought at a hobby shop) for coil-winding mandrels. Where wiring goes through a partition on the schematics, use a 1/8-inch hole drilled in the partition wall.

After you double-check your wiring, install the circuit boards in their shielded enclosures. Tack-solder the ground plane of the circuit to one side of the enclosure. Do not install the tops of the enclosures yet—we have testing to do!

Because of the power involved, build the L-pad sampler carefully. The circuit board used to mount the resistors has no copper on either side except at the corner on the far side of the SO-239 connectors. This small piece of ground plane is covered with masking tape before the copper is etched with ferric chloride. The 51-Ohm resistor is grounded here. A ground wire is then taken from here to a lug at the BNC connector (make the lug from copper shim stock).

Mount the board using 4-40 × 3/4-inch screws. Use 5/16-inch-diameter × 1/2-inch-long aluminum tubing slipped over each 4-40 screw to stand the circuit board off. Be sure the resistor pairs are separated from each other by 3/8 of an inch. The physical layout of the resistors should look like the schematic in Fig. 3. The "fuse" wire, which is a single, hair-thin strand of copper wire from an old "zip" cord, must be at least 1/2 inch long. The L-pad is built in a medium-size minibox.

I mounted the shielded enclosures and the sweep generator/power-supply board in a 3-inch-high × 12-inch-wide × 18-inch-deep aluminum chassis. (Refer to Photo D for typical mounting.) Individual circuits are tested before final mounting and installation of the enclosure tops.

Testing and Alignment

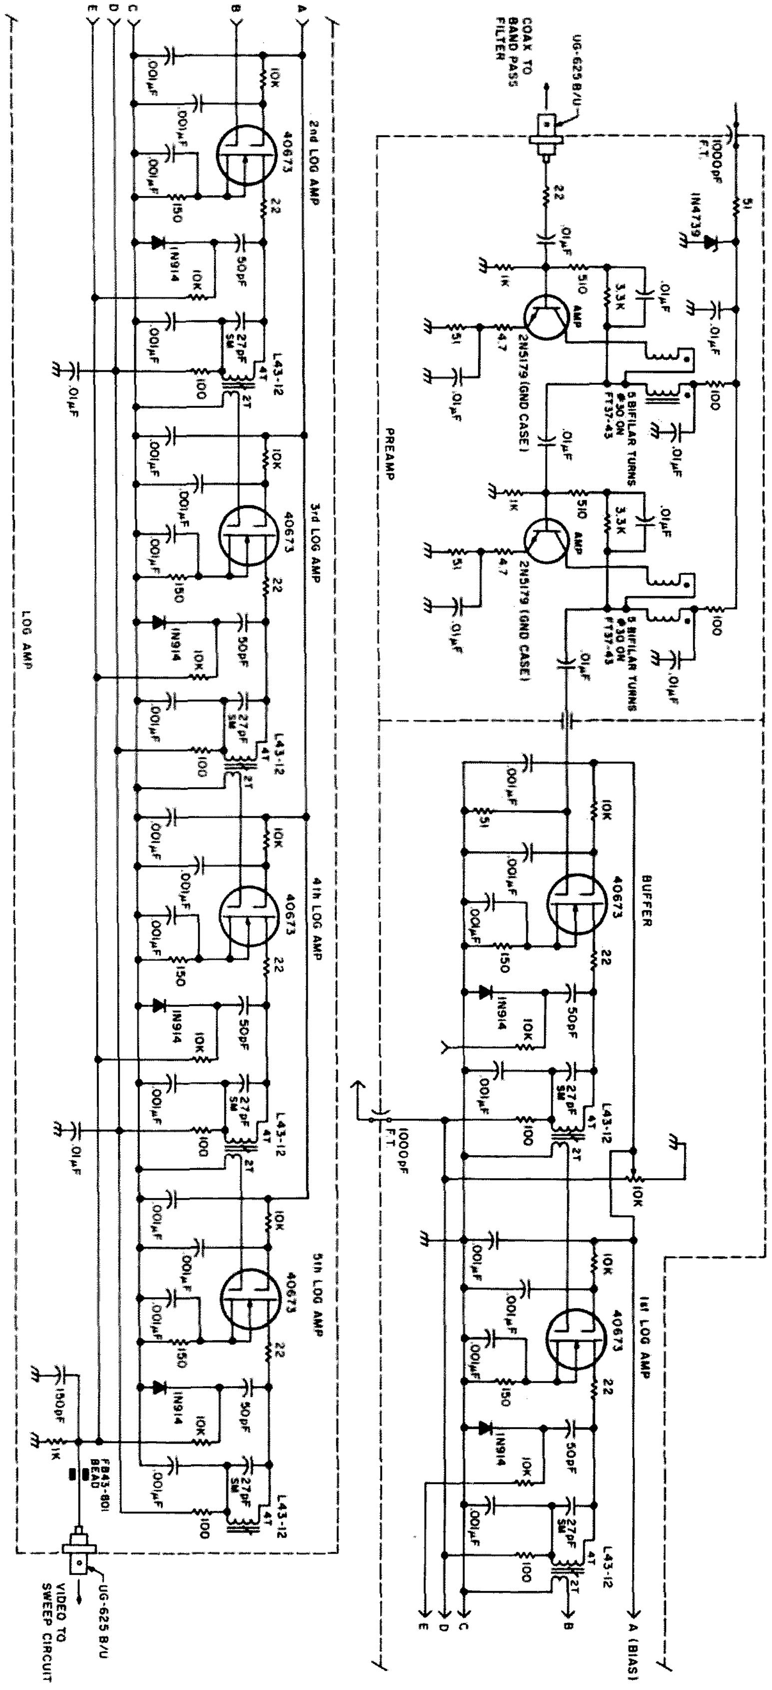
The minimum test equipment needed to align and test the HF spectrum ana-

lyzer includes a high-impedance volt ohmmeter, a 350-MHz frequency counter, and a 5-MHz bandwidth, single-channel, dc-coupled oscilloscope with a triggered sweep. A grid-dip oscillator also is useful. You should make up several 2-foot RG-58 cables with BNC connectors. These will be used during testing. For best results, testing and alignment should be done in the order listed below.

Power Supply Testing. Check the resistance between the primary and secondary of the wallplug transformer before use. It should show an open circuit. Check the secondary ac voltage. It should be 12 V ac to 15 V ac with no load. Hook the 12 V ac to the power supply and check the 12 V dc, 24 V dc, and −6 V dc outputs. They should be within 1/2 volt.

Sweep Generator Testing. Connect the power supply to the sweep generator and turn the power supply on. Check pin 2 of the 555 IC with your oscilloscope. You should find a 10-Hz-to-12-Hz ramp waveform. The bottom of the waveform should be at 4 volts and the top of the waveform at 8 volts. The front of the ramp (long slope) should appear straight. You should find a similar ramp at the X-axis output connector. This ramp will be between −0.6 volts and 3.4 volts.

Check pin 8 of the TL084C op amp. You should find a pulse train with a 10-Hz-to-12-Hz repetition rate. The pulse train should



Note 1. Resistors are 1/4 W, 5%; unspecified capacitors are 50-V ceramic.
Note 2. Capacitors marked "SM" are ±5% silver mica.
Note 3. L43-12 rf transformers and FT37-43 toroids are available from Amidon.
Note 4. Shielded box made from single- and double-sided G-10 circuit board plus copper shim stock.

Fig. 7. Preamp and log amp.

be high (20 volts) about 20% of the time and low (−3 volts) about 80% of the time.

Turn the frequency-span pot fully clockwise (no ramp) and set the center-frequency pot mid-range. You should find 6 V dc to 12 V dc on pin seven of the TL084C op amp (vco-tuning voltage). Vary the setting of the center-frequency pot. The vco-tuning voltage should vary from −3 volts to 21 volts. Set the center-frequency pot for a 10-volt output. Turn the frequency-span pot counterclockwise until you have a ramp waveform from 2 volts to 20 volts (readjust the center-frequency pot as needed). This completes preliminary sweep generator testing.

If your sweep generator fails to act as above, recheck component values and circuit hookup for problems. Refer to the theory of operation for additional hints.

Vco Testing. Connect the vco-tuning voltage from the sweep generator to the vco. Ground the RG-58 shield at the vco enclosure. Connect 12 V dc from the power supply to the vco power input. Disconnect one side of the oscillator coil for a moment. Power up and check the MRF901 collector voltage. It should be about 6 V dc to 8 V dc. If it is too high, reduce the value of the 100k bias resistor. If it is too low, increase the value of the bias resistor. You can't use a pot here! Once the collector voltage is verified, power down and reconnect the coil.

Power up and connect your counter to the vco rf test jack. Turn the frequency-span pot fully clockwise (no ramp) and adjust the center-frequency pot for a 3-volt output. Your counter should read about 90 MHz. Adjust the vco coil spacing to get the vco in the 89.5-MHz-to-90.5-MHz range. Check the dc output from the rf detector of the vco

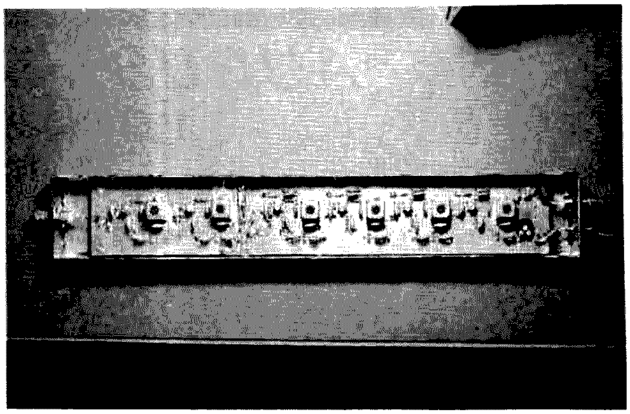


Photo H. Log amplifier layout. Note strip design.

amplifier output for a 0.8-V-dc-to-1.3-V-dc level. Adjust the spacing between the vco coil and the amplifier pick-up loop, if necessary, to obtain the proper detector output.

Set the center-frequency pot for a 150-MHz oscillator output. You should have a tuning voltage of about 18 V dc. Check the rf-detector output voltage again to be sure it's still between 0.8 V dc and 1.3 V dc. Monitoring the dc voltage from the rf detector with your scope, tune the center-frequency pot back and forth between 3 volts and 18 volts. The detector output voltage may smoothly vary some but should not "jump." An abrupt voltage change indicates a parasitic oscillation. If this should occur, work with your oscillator layout (very short leads) to get rid of it.

A tuning voltage of less than 1 V dc may cause the oscillator output to be erratic in frequency and amplitude. This is not a problem. Once the vco oscillator and amplifier are operating properly, install the vco enclosure top.

Preamplifier and Log Amplifier Testing. Connect 12 V dc to the preamplifier and log amplifier circuits and power up. Turn the frequency-span pot fully clockwise (ramp off) and adjust the center-frequency pot for 90 MHz at the vco rf test jack. Disconnect the frequency counter. Hook the attenuator box to the vco rf test jack with a two-foot RG-58 cable. Hook the output of the attenuator to the input of the preamplifier with another two-foot cable.

Set the bias pot on the log amplifier about mid-range. Monitor the dc output of the rf detector on the log amplifier buffer. Tune the buffer transformer slug for peak output. Use the attenuator to set the detector output to 0.2 V dc. Now adjust the bias pot of the log amplifier for peak output. Adjust the attenuator for a just-detectable output at the log amplifier buffer. If all seems well with the preamplifier, install the top on its enclosure. Prepare the top for the log amplifier section. Drill 1/8-inch-diameter holes in the top over each i-f transformer location and over the bias pot. (Use drafting vellum as a template.)

Hook the oscilloscope to the video output of the log amplifier. Adjust the slugs in each log amplifier stage for peak video output. The tuning of each stage should be smooth, and the tuning of the bias pot should also be smooth. If the video output from the log amplifier jumps suddenly while tuning, you may have a self-oscillation in the log amplifier. If this happens, carefully work with your layout. Ferrite beads, extra bypass capacitors, and small copper shim stock shields can be used to eliminate the problem. My i-f strip was quite stable, so I do not think you will have a problem.

If you live near a commercial FM station, it may interfere with your tuning efforts. Tape the shield top on the log amplifier during initial tuning to help eliminate this problem. As soon as it appears that the log amplifier is working, solder on the top. Once the top is soldered on, it will totally eliminate the interference.

Bandpass Filter Tuning

Set the vco to 90 MHz. Hook the attenuator between the vco rf test jack and the bandpass filter input. Hook the bandpass filter output to the preamplifier and log amplifier. Monitor the video output of the log amplifier on your oscilloscope. With the tops off the bandpass sections, you should get some signal. If not, temporarily bridge the input and output sections with a 1-pF capacitor tack-soldered at the input and output tap points. Tune the input and output stages for peak response. Remove the 1-pF capacitor if used. Now peak the two middle stages. You probably will get an overcoupled response (double-hump). Just center the tuning between the humps.

Now install the shield tops, one at a time. Tune all bandpass stages after each top is installed. Tuning will become very sharp, especially if you are using air-variable tuning capacitors instead of piston trimmers. When the last top is installed, carefully peak all stages.

Set up your oscilloscope for X-Y operation, using the X-axis output of the sweep generator for the oscilloscope horizontal input and the log amplifier video output for the vertical input. Gradually turn the frequency-span control counterclockwise until you get a sweep display of the filter

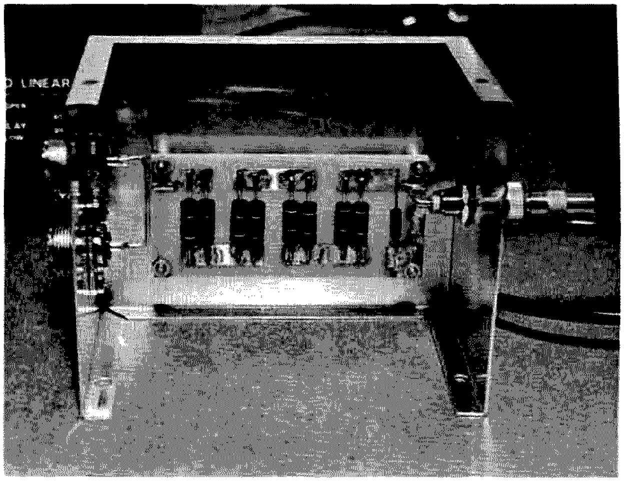

Photo I. L-pad sampler.

bandpass. Make fine adjustments for a smooth bandpass shape. Stagger-tune the two middle bandpass filter sections just a bit to sharpen the nose of the filter. Be sure to put in enough attenuation to keep the video output from the log amplifier under two volts during the bandpass filter tuning procedure.

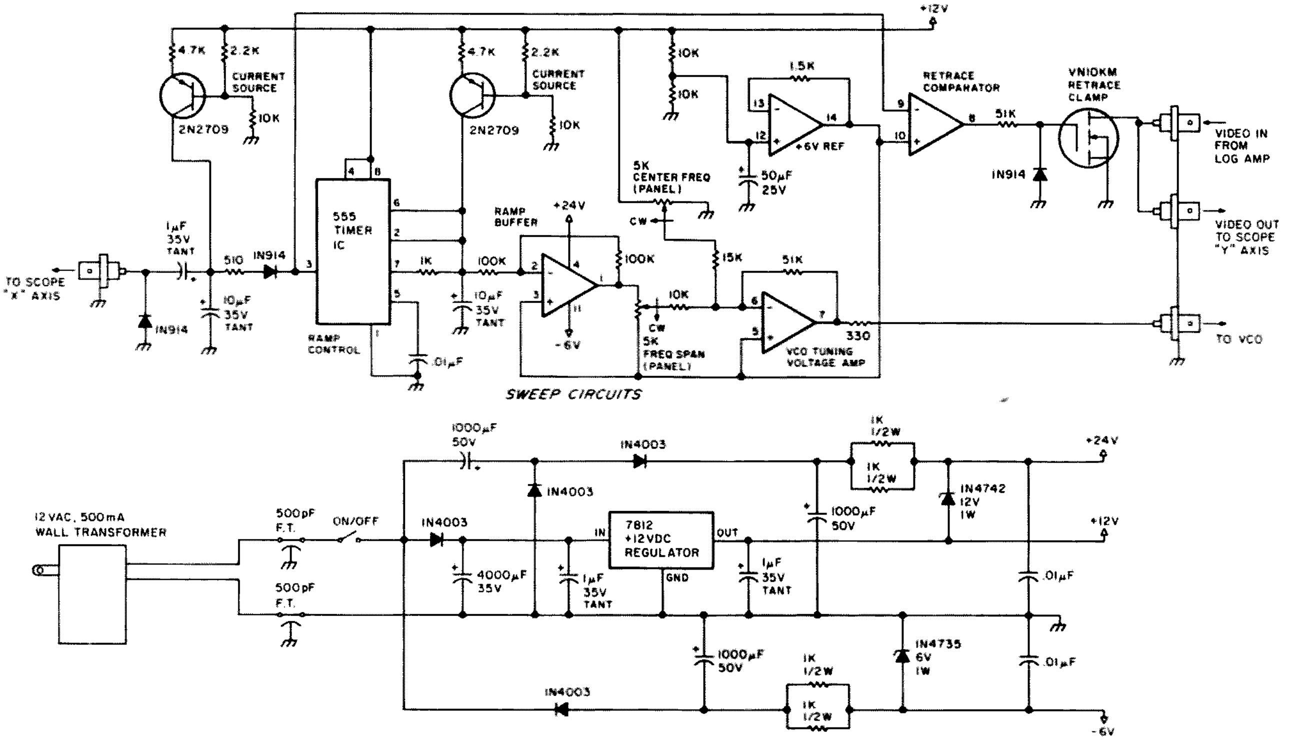
If it seems that you have an over-coupled response in your filter, narrow the aperture between the two middle bandpass filter sections. If the filter tunes sharply but exhibits high loss, then widen the aperture between the two middle sections.

Final Setup

Install all circuitry in your chassis and complete all wiring and coaxial cable hookup. Set the analyzer upside down in front of your scope. Connect your oscilloscope to the analyzer X- and Y-axis outputs. Set up the oscilloscope again for X-Y operation. Turn the analyzer on (no signal). Turn the frequency-span pot fully clockwise (no ramp). Using your frequency counter at the vco rf test jack, set the vco for 90 MHz operation with the center-frequency pot. You should see two horizontal lines about 2 volts apart. Rotate the frequency-span pot counterclockwise a little. You should see the bandpass-filter response again. This is due to mixer leak-through and is normal.

Set the retrace line (lower straight line) under the bandpass response curve at the bottom of the CRT screen. Widen the trace with the oscilloscope controls to reach across the screen. Turn the frequency-span pot fully clockwise again. Set the vco frequency to 120 MHz. Now turn the span pot counterclockwise until the zero-frequency half-spike appears on the left side of the screen. There should also be some grass above the retrace line along the bottom on the screen. The analyzer should now be scanning 0 to 60 MHz.

Feed a small 30-MHz signal from a grid-dip oscillator (use a pick-up loop as shown in Photo J) or a low-power-signal generator to the analyzer through the attenuator. You should now see the 30-MHz signal spike about mid-screen. You may also see the 2nd harmonic of the 30-MHz signal on the right edge of the screen. Adjust the attenuator so that the 30-MHz signal is about



Note 1. Wall transformer available from Jameco.
Note 2. Other devices available from Radio Shack.
Note 3. TL084C is quad op amp.
Note 4. 500-pF threaded feedthroughs available from Alaska Microwave.

Fig. 8. Power supply and sweep circuits.

the same height as the zero-frequency half-spike. If things have gone well so far, you are getting a signal through the low-pass filter and mixer, so you can now install their enclosure tops.

Set the frequency-span control so that the 30-MHz signal spike is about two scope divisions wide. Now fine-tune the bandpass filter again and re-peak the log amplifier. Switch the 10-dB attenuator section in and out while adjusting the vertical gain of the oscilloscope so that the signal height changes one CRT division. Now switch a 20-dB section in and out. Signal height should change two CRT divisions. Readjust the frequency span control for a 0-to-60-MHz analyzer tuning range.

Increase signal strength until the first small spike pops out of the grass between the 0- and 30-MHz signals. This is slightly above the overload point of the analyzer. The 30-MHz signal spike should be near the top of the CRT screen (8th vertical division). Full-scale inputs should be the next (7th) CRT division down. Touch up the oscilloscope controls if necessary. The zero-frequency half-spike will be about six divisions tall. Switch all attenuation out and reduce the signal generator output so that the 30-MHz test signal is seven divisions tall. Check the vertical calibration of the analyzer over the attenuator's 59-dB range.

Using your signal generator and frequency counter, take notes on the horizontal calibration of your analyzer. This is done by centering a signal from your signal generator on each CRT horizontal division (vertical line) and recording its frequency. Your analyzer is now ready for use. But first, test the L-pad carefully!

Hook up your L-pad to your transmitting equipment. Be sure everything is grounded properly. I suggest mounting the L-pad and attenuator on an aluminum plate which is in turn wall-mounted. Ground the plate! Do not connect the attenuator to the L-pad yet. Connect your transmitter to an swr meter, the swr meter to the L-pad, and the L-pad to your dummy load. The L-pad should introduce little, if any, swr. Starting with low power (100 Watts or less), key down for 30 seconds. Power down your transmitter completely and quickly inspect the inside of your L-pad. The "fuse" should be OK and nothing should be hot. Continue testing to full station power.

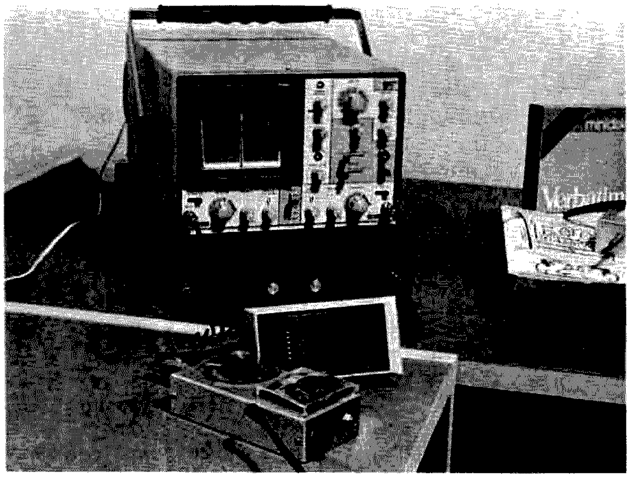


Photo J. The spectrum analyzer can easily be tuned up with simple test equipment.

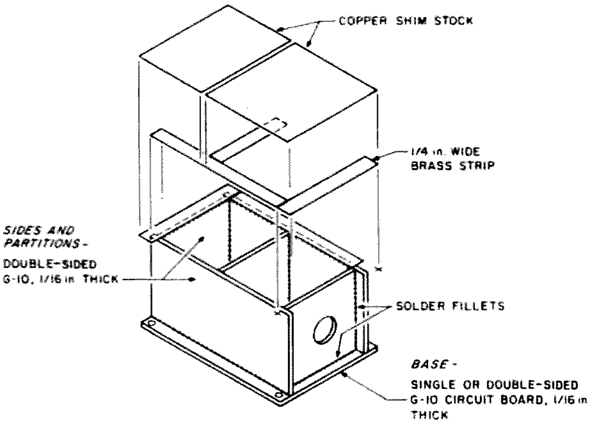
If everything has gone well, then power down your transmitter completely and connect the attenuator to the L-pad. Switch in all attenuation and connect the attenuator to the spectrum analyzer. Remember that the analyzer and oscilloscope cases should be solidly grounded. Starting again with low power, key down and adjust the attenuator for a full-scale spectrum analyzer display. How does your spectrum look?! Always switch in full attenuation before increasing power. Remember, do not go over one kilowatt continuous output (2 kW p-p). Do not attempt to use the spectrum analyzer system where your swr is greater than 2:1. Always be sure you are using an L-sampler with a high enough power rating!



Note 1. Solder G-10 circuit board and brass strips with 40-W iron.
Note 2. Solder copper shim stock with 25-W iron.

Fig. 9. Shielded box construction detail.

Component Sources and Substitutions

It often is lamented that home-brewing projects is difficult these days because of poor component availability. I started seriously experimenting with electronics 20 years ago in the good old days of component availability. The difference between now and then is that we have about a thousand times more components to experiment with!

It's simply a matter of motivation and tenacity. You can get any component that you need. True, Mom and Pop's local TV component place doesn't carry everything, but they may be able to order it for you. Don't be afraid to contact a manufacturer or a big distributor like Hall-Mark, Arrow, Allied, etc. They are usually glad to work with you (although order minimums can be an occasional problem). Best of all, look at the ads in this magazine. There are several dozen mail-order distributors which market primarily to the experimenter.

On specifics: You can get circuit board stock, chemicals, drill and router bits, etc., from Kepro in Fenton, Missouri. You can get MRF901s, 40673s, 500-pF and 1000-pF feedthrough capacitors from Alaska Microwave Labs in Anchorage, Alaska. You can get ferrite beads, toroids, and i-f transformers from Amidon Associates in N. Hollywood, California. Small air-variable capacitors for the bandpass filter are available from Radiokit in Greenville, New Hampshire. You can get resistors, capacitors, 555 ICs, TL084C quad op amps, VMOS transistors, and many of the parts discussed above from Radio Shack. You can get

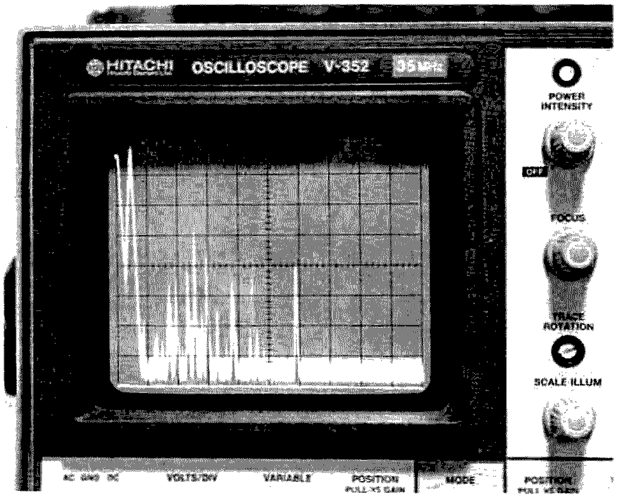


Photo K. 0-to-60-MHz spectrum on longwire antenna, using accessory preamplifier.

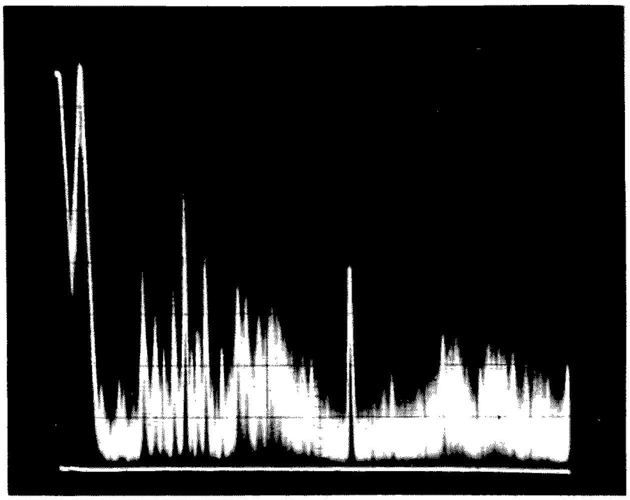

Photo L. 0-to-60-MHz spectrum on longwire antenna with my trusty but noisy computer on.

wall transformers and tantalum capacitors from Jameco in Belmont, California. 2N5179s are carried by most TV parts houses. The double-balanced mixers can be ordered directly from Mini-Circuits in Brooklyn, New York. See, you have no excuse!

OK, the MV109s might be a slight problem. An MV209 or MV309 should also work. I got my stock from Hall-Mark. If you run into a problem getting these diodes, pick up the phone and call Motorola Semiconductor in Phoenix, Arizona, for help.

The high frequency spectrum analyzer should be fairly tolerant of component substitutions except in the vco oscillator circuit and the L-pad. For example, the "hotter" 3N211 could substitute for the 40673 if you crank its gain down a bit with the log amplifier bias pot. You could use MRF901s in place of the 2N5179s (don't try to go the other way!). Solid copper conductors (#12) stripped from house wiring can be used for coil stock in the vco and bandpass filter. Any decent electrolytics of the proper capacitance and voltage rating can be used in the power supply and sweep generator circuits. Electrolytics could also be used in place of the tantalum capacitors in a pinch. Try to get close-tolerance parts in this case.

Useful Accessories

You can duplicate the 2-stage wideband-preamplifier circuit to use as an accessory ahead of the attenuator. This will allow you to view the 0-to-60-MHz radio spectrum on a longwire antenna and quickly judge the band conditions through six meters. Vco frequency-tuning is somewhat nonlinear, which is typical of simple wideband oscillators. A 6-MHz crystal oscillator driving a TTL Schmitt trigger makes a useful calibrator. The output of the TTL gate contains every harmonic through 60 MHz. Lightly couple the TTL gate to the spectrum analyzer input with an insulated wire antenna placed near the analyzer input connector. A momentary-on push-button can be used to activate the calibrator.

Analyzer Applications

We have talked about using the HF spectrum analyzer to monitor transmitting equipment. This was the primary application I had in mind when I designed the analyzer. It is especially useful to hams who are home-brewing their own HF transmitters or linears. It is also useful for checking low-pass filter performance and band conditions. I'm sure you will find other applications.

The analyzer has a 50-Ohm input impedance and is dc-coupled. Be sure to add a blocking capacitor ahead of the attenuator if you are going to look at an rf signal that is riding on a dc level. Stay away from high-voltage dc circuits. The bandpass of this analyzer is too wide for looking at SSB modulation linearity. However, this can be judged adequately from a two-tone pattern on a normal oscilloscope.

From Here

This project demonstrates that a useful spectrum analyzer can easily be built from relatively common and inexpensive components. Avid experimenters should treat this design as a starting-off point. Meanwhile, let's get those transmitter spectrums cleaned up! If you would like to ask me a question about the analyzer project, please send an SASE. 73! ■

Specifications for HF Spectrum Analyzer

Frequency range	0 to 60 MHz
3-dB bandwidth	220 kHz
30-dB bandwidth	1,100 kHz
3:30-dB shape factor	1:5
Dynamic range	60 dB
Spurious responses	60 dB below full-scale
Noise floor	65 dB below full-scale
Full-scale input	−8 dBm ±2 dBm
Y-axis output	0 to 2.5 volts
X-axis output	−0.5 to +3.5 volts
Y-axis calibration	10 dB/division
X-axis calibration	6 MHz/division (approximate)
0 to 8 MHz	4 MHz ± 0.75 MHz/division
8 to 24 MHz	8 MHz ± 1 MHz/division
24 to 60 MHz	6 MHz ± 1 MHz/division

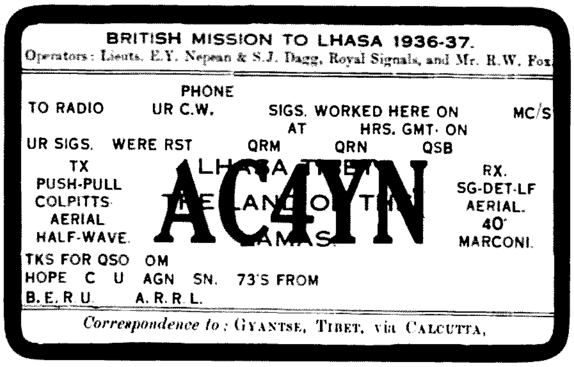
The AC4YN Story

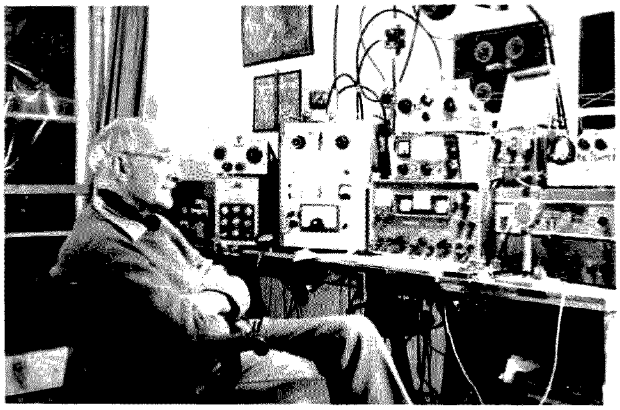
—a Tibetan adventure, circa 1936–1937

In 1936, it was decided to send a political mission to Lhasa in Tibet. I was then a subaltern in Peshawar District Signals on the northwest frontier of India.

At that time, Tibet was in a politically weak position. The Dalai Lama had died and his reincarnation had not yet been found. The Tashi Lama was on a visit to China, and the Chinese, who had always considered Tibet to be a province of China, wished to bring him back to Tibet with an escort of their army. A regent had been appointed to cover this period.

The Tibetan government, therefore, invited the mission to Lhasa with two objectives. The primary one was to persuade the Tashi Lama to return to Lhasa, to march out beyond Lhasa, meet him, and bring him back to Lhasa in triumph without an escort of the Chinese army. The second objective was for us to review the Tibetan army and advise on its improvement with a view to making Tibet a more effective buffer state between the northeast frontier of India and China.





G5YN (ex-AC4YN, VUQ, VU2YN, LA9YC, VS1YN, DL2YN) at home.

The political side of the mission was handled by the leader, the late Sir Basil Gould, who, at that time, was B. J. Gould, Esq., political officer, Sikkim, and by H. E. Richardson, Esq., British trade agent, Gyantse, the late Col. Freddy Spencer Chapman, personal assistant to Gould, and Rai Bahardur Norbhu, a high-ranking English-speaking Tibetan.

The health of the mission was in the hands of Captain W. S. Morgan of the Indian Medical Service. While the mission was in Lhasa, he also did a great deal of work for the Tibetans. He held many clinics and carried out many successful operations for cataracts under what, by modern standards, would have been considered very primitive conditions.

Military matters were in the hands of Brigadier Philip Neame VC DSO, and communications were looked after by Lieut. Sidney Dagg and myself.

Communications in Tibet were rudimentary. The Indian Posts and Telegraphs operated as far as Gyantse, where the British trade agent had his post supported by a squadron of Indian mounted infantry. Beyond Gyantse, the mail was carried by mounted runners. A telegraph line operated as far as Lhasa. It was a single strand of galvanized iron wire supported on light wooden poles with no special insulation. It operated single-current simplex earth return. One could tap in not only at Gyantse, but also at each rest house along the route. Mounted linemen patrolled the route re-erecting any poles that were blown down and repairing breaks in the line.

If we went beyond Lhasa, we would no longer have access to this circuit. It would therefore be necessary for us to take transportable wireless with which we could send back our diplomatic traffic. Another important reason for taking wireless on the mission was to outface the Chinese. They had a transmitter at Lhasa although I never heard it. As it happened, we never went beyond Lhasa. The Tashi Lama died before we succeeded in persuading the Chinese not to send an escort of their army.

The responsibility for producing radio equipment was given to Northern Command Signals; Lieut. Sidney Dagg of that regiment was given the task. As no suitable service equipment was available, he had a transmitter and receiver built in the regimental workshops

at Rawalpindi. It must be remembered that everything was carried on pack animals—ponies or yaks—in panniers two to an animal, each one not weighing more than one maud (80 lbs.).

Dagg produced the following equipment:

- The main transmitter, consisting of a self-excited push-pull Colpitts oscillator using two AT-50 triodes with an input of 100 Watts.
- A balanced Collins coupler to couple the transmitter to the open-wire aerial feeders.
- An Eddystone "All World Four" (1-V-2) battery receiver.
- A rotary transformer to convert 12 volts dc to 1000 volts dc at up to 100 milliamps.
- A Phillips record player—turntable, pick-up, and amplifier—operating on 230 volts ac.
- Two twelve-inch moving-coil loudspeakers. (We had baffles made locally on arrival.)
- One transverse-current carbon microphone.
- One 12-volt dc to 230-volt ac rotary converter.
- One 550-Watt Stuart Turner charging engine.
- Four six-volt, 120-Ampere-hour batteries.
- Two 36-foot steel sectional masts.
- Lots of aerial wire, insulators, and Eddystone 4-inch feeder separators.

I brought a few things of my own from Peshawar:

- A 1-V-1 receiver which I had built myself. This covered 10 to 550 meters using Eddystone plug-in coils. The tuning control was a Utility 100:1 slow-motion dial. The receiver proved much more efficient than the All World Four. The tuning and reaction controls were much smoother and the signal/noise ratio very much better. Much to my sorrow, I was made to leave it behind when I left the mission.

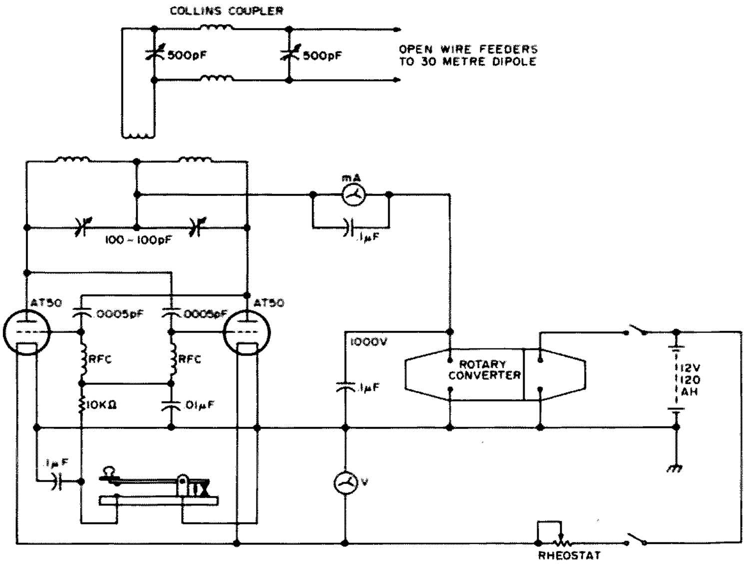


Fig. 1. AC4YN transmitter.

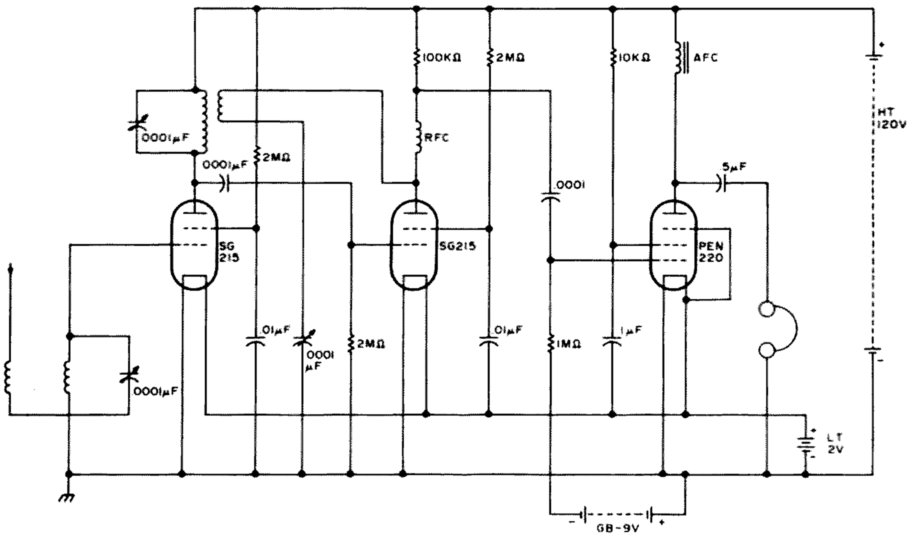

Fig. 2. AC4YN receiver.

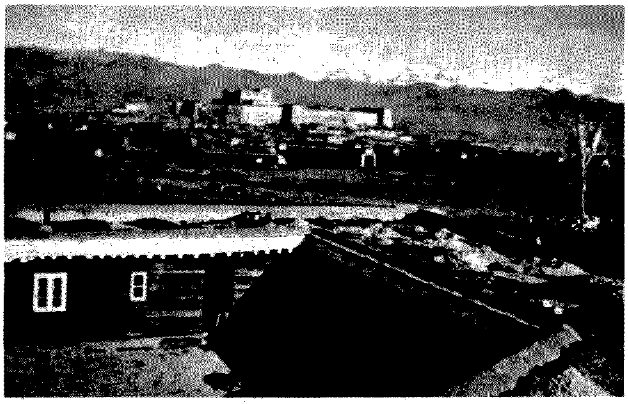
- A simple audio amplifier ending in two PX-4 triodes in push-pull to enable my receiver to operate a loudspeaker for broadcast reception.
- 45 feet of duralumin tubular mast in 5-foot sections, the property of Peshawar District Signals. I had to leave this behind also, much to the fury of my commanding officer.
- My own key, a pair of headphones, and a small box of bits and pieces. Unfortunately, I no longer have this key as the Post Of-



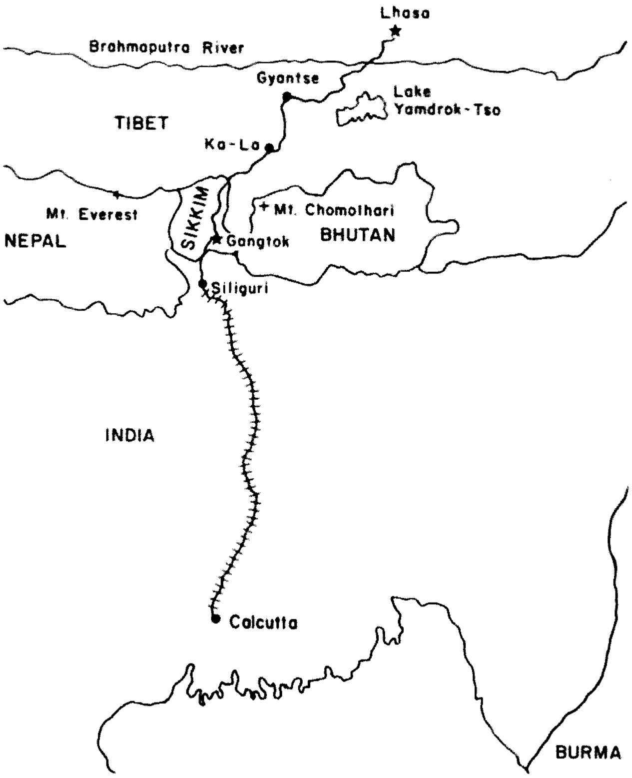
View from roof of rest house at Phari Village and jong in middle distance. Himalayas in background.

fice "lost" it when they had my equipment in custody during the last war.

Before joining the mission, I was sent to Simla, the summer hill station of army headquarters. There I gained experience in operating the control station of the army group with which we would be communicating from Lhasa. It was known as the VV group as all stations had a three-letter callsign, of which the first two were VV. The mission call was VUQ. I also was briefed to check the accuracy of *The Army Route Book of Tibet* and look out for any possible landing grounds.

From Simla, I travelled across India to Calcutta where I joined Dagg. We did some shopping and then went on to join the rest of the mission. We first traveled by train across the Plain of Bengal to Siliguri, the railhead in the foothills of the Himalayas. I chiefly remember the flatness of the country and the paddy fields.

At Siliguri, we transferred to a taxi and had a hair-raising and spectacular drive up the beautiful valley of the river Teesta. At one point, we crossed the river by a bridge which spanned a gorge in one magnificent arch, with the river racing far below. The Teesta is a tributary of the Brahmaputra.



The route from Calcutta to Lhasa. (Map from 1930s sources by Alan R. Phenix.)

We arrived safely at Gangtok, the capital of Sikkim, where Sir Basil Gould had his residency. Already at Gangtok were Freddy Chapman and Brigadier Philip Neame. Chapman not only acted as PA [personal assistant] to Sir Basil but was also in charge of cinematography, botany, ornithology, and zoology. Here, Dagg and I took the opportunity to check our radio equipment. The transmitter worked well, and we called in on the VV group. We also checked that the receivers would bring in the BBC overseas service for news, etc. We did not have time to try out the amateur bands at that time.

We then divided the equipment into 80-pound loads for back transport. The most awkward load was the charging engine, which weighed 120 lbs. In the Army, this was carried as a top load on a Class I mule. However, we had no proper pack saddles and the ponies would not have been strong enough. Finally, it was lashed to two stout bamboo poles and carried by four coolies.

When we set off, our entourage down to the last servant and sweeper was 50 strong, including 25 pack animals and their drivers. These were ponies at first and yaks later. In those days, the motor road ended at Gangtok, so from then on we either walked or rode.

As far as the halfway point, Gyantse, there were good rest houses at each stage in which we could spend the night in comfort. The first day's journey was through rain forest, where rhododendrons grew in thirty-foot trees and leeches abounded. The first halt was at Karponang at 9,500 feet, just short of the Tibetan border. I remember suffering from mountain sickness here, but it passed off in about half an hour.

Next day, we crossed into Tibet by the Natu La Pass at 14,600 feet and dropped down into the Chumbi Valley. Over the pass it was much dryer as the monsoon drops most of its moisture on the southern slopes of the Himalayas, leaving Tibet a comparatively dry country with only a few inches of snow despite a very hard winter.

Lieut. Dagg unpacks and tests record player at an intermediate halt. Freddy Chapman at right.

How the charging engine traveled to Lhasa.

In the valley, we spent three nights, one at Champitung, 13,350 feet, another at Yatung, 9,950 feet, and a third at Gautsa, 12,600 feet. At Yatung there was a detachment of Indian mounted infantry. The next day we climbed up out of the valley on to the main Tibetan plain at 14,300 feet. We stopped the night at Phari, which was a small town with a fort, or jong, and a good rest house.

At each of these halts, Dagg and I set up a receiver to check on the VV group and take down news broadcasts from the BBC. It was a year after sunspot maxima, so HF propagation was good and there was nothing unexpected about what we heard. The only embarrassment was the charging engine. Dagg had been given no chance to test it at high altitude, and as we gained height, it developed less and less power due to shortage of oxygen. At 6,000 feet it would just work. At 10,000 feet it would start and run when cold. As soon as it warmed up it stalled, and that was that.

We sent a signal home to Stuart Turners who, in due course, sent out a pair of variable-jet carburetors. They did not arrive until after I had left the mission, but I was told that when they were fitted the engine ran very well, developing more than its rated power.

Tibetans working the hand charger.

The transmitter, receiver, and Collins coupler installed in the barracks at Gyantse.

While Dagg and I were dealing with radio matters, Chapman was studying the local fauna and flora. In due course, he sent back a magnificent collection of seeds and pressed flowers to Kew Gardens.

There were six more night halts before reaching our major intermediate halt at Gyantse: Tuna, 15,000 feet, Dochen, 14,900 feet, Kala, 14,850 feet, Samada, 14,100 feet, Kangmar, 13,900 feet, and Saugang at 13,000 feet. Gyantse itself was at 13,100 feet. The way was mainly over a stony plain with mountains rising to 20,000 feet in the distance. Sometimes we passed through rocky gorges and occasionally by streams. We passed close under Mt. Chomolhari, a beautiful snow-covered cone rising to 24,000 feet.

Gyantse is a fair-sized town with monasteries, a jong, the headquarters of the British trade agent, and barracks for a company of Indian mounted infantry, at that time the 2/7 Rajputana Rifles. Here several official receptions took place. For instance, we had to time our arrival carefully so as to be three miles from the town at 11:00 am. We were met here by Raja Tering, a cousin of the Maharajah of Sikkim. Half a mile further on, we were met by Mr. Richardson (the British trade agent), Capt. Salomons, an escort of mounted infantry, and Capts. Guthrie and Morgan of the IMS, the Army surgeons. Captain Morgan accompanied us for the rest of the mission. A mile further on, the eastern and western jongpens met us, and finally the Tibetan trade agent and the Abbot of Gyantse Gompa. This order of precedence is very strict. The most senior official meets you nearest your destination and the most junior farthest out. On each occasion, ceremonial scarves of white natural silk are exchanged.

Here, Dagg and I were able to have a thorough sort-out of our gear. We cut

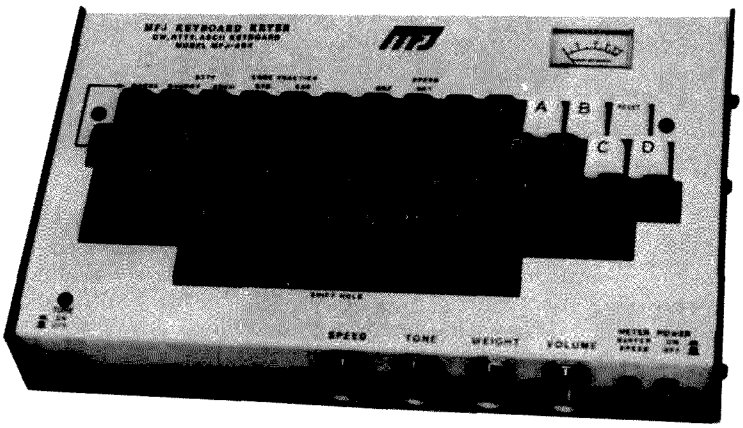
MFJ Super Keyboards



5 MODES: CW, Baudot, ASCII, memory keyer, Morse code practice. TWO MODELS: MFJ-496, $339.95. 256 character buffer, 256 character message memory, automatic messages, serial numbering, repeat/delay. MFJ-494, $279.95. 50 character buffer, 30 character memory, automatic messages.

MFJ brings you a pair of 5 Mode Super Keyboards that gives you more features per dollar than any other keyboard available. You can send CW, Baudot, ASCII. Use it as a memory keyer and for MORSE code practice.

You get text buffer, programmable and automatic message memories, error deletion, buffer preload, buffer hold, plus much more.

MODE 1: CW

The 256 character (50 for 494) **text buffer** makes sending perfect CW effortless even if you "hunt and peck."

You can preload a message into the buffer and transmit when ready. For break-in, you can stop the buffer, send comments on key paddles and then resume sending the buffer content.

Delete errors by backspacing.

A meter gives buffer remaining or speed. Two characters before buffer full the meter lights up red and the sidetone changes pitch.

Four programmable message memories (2 for 494) give a total of 256 characters (30 for 494). Each message starts after one ends for no wasted memory. Delete errors by backspacing.

To use the **automatic messages,** type your call into message A. Then by pressing the CQ button you send CQ CQ DE (message A).

The other automatic messages work the same way: CQ TEST DE, DE, QRZ.

Special keys for KN, SK, BT, AS, AA and AR.

A lot of thought has gone into human engineering these MFJ Super Keyboards.

For example, you press only a one or two key sequence to execute any command.

All controls and keys are positioned logically and labeled clearly for instant recognition.

Pots are used for speed, volume, tone, and weight because they are more human oriented than keystroke sequences and they remember your settings when power is off.

Weight control makes your signal distinctive to penetrate QRM.

MODE 2 & 3 (RTTY): BAUDOT & ASCII

5 level Baudot is transmitted at 60 WPM. Both RTTY and CW ID are provided.

Carriage return, line feed, and "LTRS" are sent automatically on the first space after 63 characters on a line. This gives unbroken words at the receiving end and frees you from sending the carriage return. After 70 characters the function is initiated without a space.

All up and down shift is done automatically. A downshift occurs on every space to quickly clear garbled reception.

The buffer, programmable and automatic messages, backspace delete and PTT control (keys your rig) are included.

The ASCII mode includes all the features of Baudot. Transmission speed is 110 baud. Both upper and lower case are generated.

MODE 4: MEMORY KEYER

Plug in a paddle to use it as a deluxe full feature memory keyer with automatic and programmable memories, iambic operation, dot-dash memories, and all the features of the CW mode.

MODE 5: MORSE CODE PRACTICE

There are two Morse code practice modes. Mode 1: random length groups of random characters. Mode 2: pseudo random 5 character groups in 8 separate repeatable lists (with answers).

Insert space between characters and groups to form high speed characters at slower speed for easy character recognition.

Select alphabetic or alphanumeric plus punctuation. You can even pause and then resume.

MORE FEATURES

Automatic incrementing serial number from 0 to 999 can be inserted into buffer or message memory for contests.

Repeat function allows repetition of any message memory with 1 to 99 seconds delay. Lets you call CQ and repeat until answered.

Two key lockout operation prevents lost characters during typing speed bursts.

Clock option (496 only) send time in CW, Baudot, ASCII. 24 hour format.

Set CW sending speed before or while sending.

Tune switch with LED keys transmitter for tuning. Tune key provides continuous dots to save finals. Built-in sidetone and speaker.

PTT (push-to-talk) output keys transmitter for Baudot and ASCII modes.

Reliable solid state keying for CW: grid block, cathode, solid state transmitters (-300V, 10 ma Max, +300V, 100 ma Max). TTL and open collector outputs for RTTY and ASCII.

Fully shielded. RF proof. All aluminum cabinet. Black bottom, eggshell white top. 12"Dx7"Wx1¼"H (front) x3½"H (back). Red LED indicates on.

9-12 VDC or 110 VAC with optional adapter.

MFJ-494 is like MFJ-496 less sequencial numbering, repeat/delay functions. Has 50 character buffer, 30 character message memory. Clock option not available for MFJ-494.

Every single unit is tested for performance and inspected for quality. Solid American construction.

OPTIONS

MFJ-53 AFSK PLUG-IN MODULE. 170 and 850 Hz shift. Output plugs into mic or phone patch jack for FSK with SSB rigs and AFSK with FM or AM rigs. $39.95 (+$3).

MFJ-54 LOOP KEYING PLUG-IN MODULE. 300V, 60 ma loop keying circuit drives your RTTY printer. Opto-isolated. TTL input for your computer to drive your printer. $29.95 (+$3).

MFJ-61 CLOCK MODULE (MFJ-496 only). Press key to send time in CW, Baudot or ASCII. 24 hour format. $29.95 (+$3).

110 VAC ADAPTER. $7.95 (+$3).

BENCHER IAMBIC PADDLE. $42.95 (+$4).

A PERSONAL TEST

Give the MFJ-496 or MFJ-494 Super Keyboard a personal test right in your own ham shack.

Order one from MFJ and try it — no obligation. See how easy it is to operate and how much more enjoyable CW and RTTY can be. If not delighted, return it within 30 days for refund (less shipping). One year unconditional guarantee.

To order, call toll free 800-647-1800. Charge VISA, MC, or mail check or money order for **$339.95** for MFJ-496, **$279.95** for MFJ-494, **$39.95** for MFJ-53 AFSK module, **$29.95** for MFJ-54 Loop Keying module, **$29.95** for MFJ-61 Clock module, **$7.95** for the 110 VAC adapter and **$42.95** for Bencher Paddle. Include $5.00 shipping and handling per order or as indicated in parentheses if items are ordered separately.

Why not really enjoy CW and RTTY? Order your MFJ Super Keyboard at no obligation today.

Using the PA equipment. The monk who enjoyed singing.

The Regent inspects the record player/PA equipment.

Ringang.

a dipole for the Army HQ group wavelength of 30 meters. Each half of the dipole was 25 feet long, and the open-wire feeders were 40 feet long. We set up the transmitter and receiver in a room in the barracks. We were lucky enough to find here a home-made charging machine which had been built to charge the battery of a broadcast receiver. It was built around a six-volt car dynamo driven by a wondrous contrivance of wooden pulleys and flapping leather belts. Cranked by coolies, it managed to produce enough charge to enable us to maintain short schedules with the VV group, but not enough to spare to enable us to make any transmission on the amateur bands.

It was now decided that Dagg should go back to Calcutta and have a new handcharger built. It had been hoped that a charging engine used by a recent Everest expedition might still be available at Katmandu, but enquiries showed that it had been disposed of. Dagg eventually rejoined us in Lhasa with a most efficient gear-driven device. It used a Ford 12-volt dynamo and had two large crank handles. Four coolies managed to produce 6 Amps through 12 volts of batteries. This rate of work is only about 1/10th HP, so they can't have been working very hard!

The political part of the mission went ahead to Lhasa, leaving me behind with the radio gear and the Bell and Howell 35mm projector. There was no point in taking these on up to Lhasa until power was available. In due course, I was summoned to join the main party.

Now, Lhasa had an electric light plant. It worked on the dc three-wire system with 440 volts of batteries having the center tap earthed. The supply was, therefore, 220 volts. Those on one wire had positive earth, those on the other had negative earth. The cells were charged by a motor generator. The motor ran at 3 kV ac. The ac was generated by a small hydroelectric plant in the foothills of the 20,000-foot mountains which rose from the 12,000-foot Lhasa plain about three miles away.

The insulation of the transmission line was a bit rudimentary, and on damp evenings there were impressive brush discharges. The stream driving the turbine froze at night during the winter so that charging could be carried out only by day.

You will realize that this was a considerable engineering achievement when you remember that every item had to be carried up from the road head by coolies and pack animals. Great credit also is due to the Tibetan official who assembled and commissioned it with only unskilled labor at his disposal and who was responsible for running it. His name was Ringang. He was one of the four Tibetans who, as boys, were sent to England and educated at Rugby. He was also responsible for the official ciphers. He arranged for our batteries to be charged by connecting them in parallel with the end cells of the 440-volt battery.

The mission was accommodated in a nice villa in a garden called the Dekiy Langka. There were not enough rooms for us all to sleep inside, so I had a tent in the garden in which I also set up the transmitter and receiver. The aerial was supported at one end on a forty-foot mast consisting of five of the eight-foot sections of duralumin. The other end was supported on one section set up on the flat roof of the house. Regular contact was kept with the control station of the VV group at Army headquarters, Simla, in the summer, and with New Delhi in the winter. All the outstations at various army stations in India and the one in Hong Kong were worked on the 30-meter wave.

Once this was organized, I looked around for the 20-meter amateur band. This was soon found and the transmitter tuned to the band by netting on to the receiver. You will remember that each half of the dipole was 25 feet and the feeders were 40 feet, making the overall length of each half 65 feet, so there was no problem in loading it up via the Collins coupler.

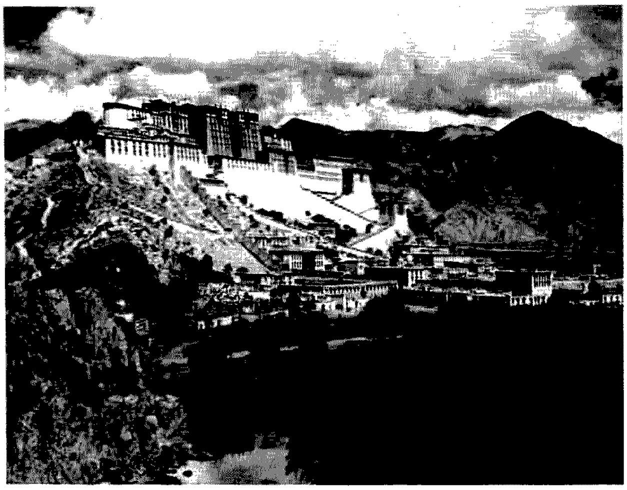
The first people to respond to that historical call, "CQ de AC4YN," were VU2 amateurs. Before the Chinese invasion, the intermediate for Tibet was AC4. There was no licensing authority, so I created the call by adding the two letters of my own callsign to the intermediate. Unfortunately, I did not make a copy of the log for my own records, so I have no recollection of individual callsigns worked.

The first DX to be worked was VK and ZL. They were so reliable that we regarded them as locals. This was very useful, as the political officer had relations in New Zealand. We were able to pass Christmas greetings between the two parties via amateur radio, earning considerable kudos both for amateur radio and Royal Signals.

As the year progressed, our signals seemed to reach further and further west until, in December, I raised my first G station. In my excitement, I asked him if he would relay messages to my family. However, I must have scared him off as he did not come back to me again.

I was not able to spend much time on the air as I had to join in a great number of the business and social activities of the mission. We attended and gave many official parties. There were visits to the Potala, the three huge monasteries (Sera, Drepung, and Kundun), the cathedral, and various temples. Although the Tibetans are Buddhists, there were still traces of ancestor and devil worship. It was always considered wise to placate any gods, spirits, or devils that may be around. One such temple was dedicated to snakes.

Besides these places, we also visited the mint, the arsenal, and the Norbu Lingha, the Dalai Lama's summer palace and gardens. Some of my time also was taken up helping Freddy Chapman with cipher work and photography. On some evenings, we gave cinema performances. These were always packed, not only with our own staff and friends, but also by as many locals as could squeeze into the room. Some of the films were old comics we had rented from a film library and brought with us. Of these, the most popular were those starring Rin Tin Tin, since they reminded locals of their own shepherd dogs.



The Potala.

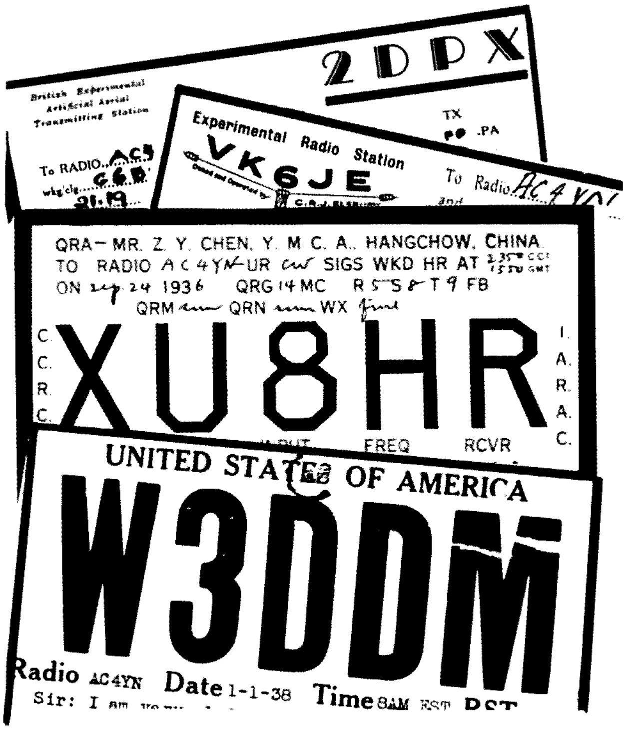
What they enjoyed most were films taken by Chapman which had been sent down to Calcutta for processing and returned to us. The appearances of themselves and their friends on the screen were greeted with loud applause. Another thing which amused them was talking into the microphone and hearing their own voices, amplified by the record player amplifier, booming out over the loudspeakers.

All too soon, the time came when I had to leave Lhasa, the mission, and all the good friends I had made up there. A frontier war had started and my commanding officer demanded my return to the regiment. So, about mid-December, I set off back with my Pathan bearer and a couple of pack ponies. Traveling light, I did double stages. Chapman came with me as far as the Yamdrok So, a vast lake between Lhasa and Gyantse, to study bird life and gather wild flowers. I crossed the upper reaches of the Brahmaputra in coracles, came back over the 16,600-foot Karo La, and went down to Gyantse. In winter, it is very cold at these heights, and a strong wind blows all day raising dust storms. If Tibetans have to travel in the winter, they do so at night when the wind drops.

I continued these double stages back to Gangtok, and then went by taxi to Siliguri and by train to Calcutta. I had to call in at New Delhi for debriefing before returning to my regiment in Peshawar.

In order to keep the radio in operation after my departure, Reg Fox, who was ex-Royal Signals, was sent up from Calcutta. He did not arrive until after I left, so I did not have the pleasure of meeting him. When the mission closed in the spring, he stayed on in Lhasa and married a Tibetan girl. He remained until the Chinese invasion, when he escaped to India where he died. Whether any of his records, logs, or equipment have survived, I do not know.

To those who are interested in reading about the mission, I recommend F. Spencer Chapman's book *Lhasa, The Holy City*, published by Chatto and Windus, London, 1938. The political officer in Sikkim's letter no. 4(7)-P.37 to the Foreign Office (dated 30th April 1937) and his diary of events are probably available from the Public Record Office, London. ■



"Smart" Squelch for SSB

Editor's Note: W9MKV and W9YAN's "Smart Squelch" overwhelmed the competition to win the first *73 Magazine* Home-Brew Contest. The authors received a $250 prize in addition to the normal article payment. You can build this trend-setting project; W9MKV offers a PC board for $7.00 and a complete parts kit is available from Radiokit, Box 411, Greenville NH 03048, for $49.95. Congratulations to W9MKV and W9YAN for a job well done.

This circuit detects the human voice but ignores noise, steady tones, and the Russian woodpecker HF radar pulses. It requires no receiver modification and works even when voice signals are below the noise level.

A squelch turns off receiver audio to eliminate annoying background noise when there is no signal. Squelch circuits in AM and FM receivers are carrier-operated. On single sideband, which has no carrier, squelching is more difficult. Most SSB rigs with squelch, e.g., the popular 2-meter multimode transceivers, use agc (S-meter) voltage to open squelch in SSB mode. Agc-operated squelch is adequate for strong signals on relatively quiet channels. Agc and VOX-type squelches open for any noise or heterodyne that exceeds a preset level. Weak signals often are missed because the threshold must be set above the noise level.

White noise sometimes can make you imagine tiny voices in the noise, but it won't fool the Smart Squelch. Detecting unreadably-weak signals is worthwhile if a change of antenna direction or receiver control settings will make them usable.

The audio-operated squelch circuit described here is similar in principle to Motorola's "Constant Sinad" squelch, a discrete-component circuit with 22 transistors.

Discriminating the Human Voice

People normally speak about three syllables per second. The squelch works by detecting voice-band energy (500-3000 Hz) which is varying in frequency at a *rate* of 0.5 to 3.25 Hz.

The circuit is a type of FM detector. It is insensitive to amplitude variations throughout the range where the input stage is not driven to saturation but background noise is strong enough to saturate the limiter. The squelch works properly with most speaker-level signals. You can connect it directly to the receiver's detector output, adjusting gain of input buffer amplifer U1A as necessary.

Performance

A receiver tuned to WWV provides a good demonstration of the circuit's capabilities. Squelch opens for voice announcements and ignores the rest of the transmissions.

The squelch can turn on well within the first spoken syllable. Speed of response depends mostly upon the rise-time of active low-pass filter U3A. The receiver is muted one second after the last voice detection. The beginning of a steady tone

Photo A. Squelch unit is attached to the right side of the HF SSB transceiver. Rectangular LEDs above the control knob indicate circuit status. (Photo by KA9FJS)

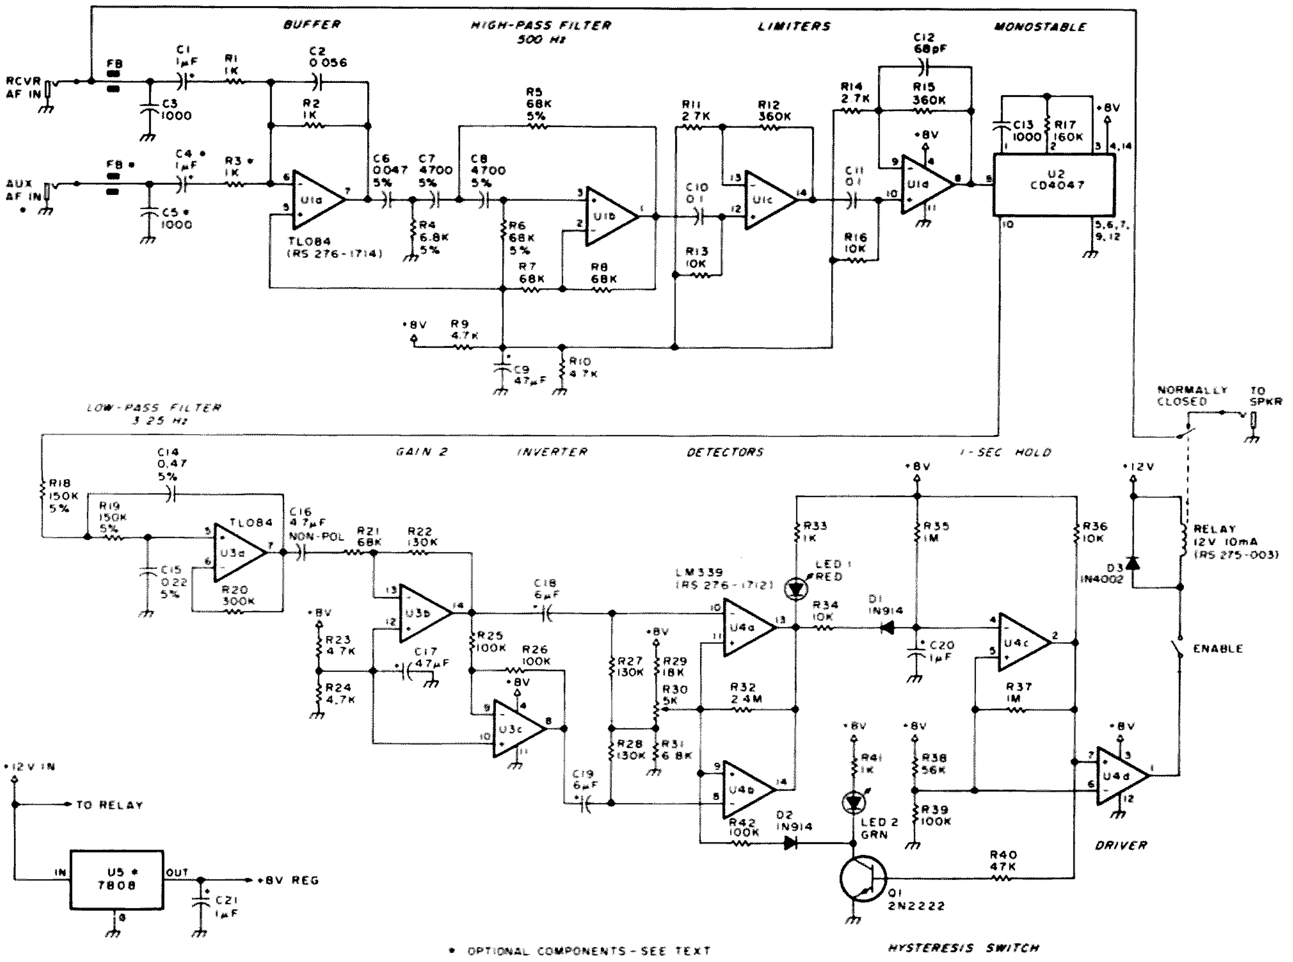

Fig. 1. Schematic diagram.

opens the squelch only momentarily. It opens intermittently on music. Response to CW depends on code speed and tone.

A single squelch circuit can control multiple receivers, unsquelching them all when any receiver detects a voice signal. (We like to monitor HF aircraft and marine frequencies plus 144.2 MHz—the 2-meter SSB calling frequency.)

The squelch is useful when rf radiation from computer systems overwhelms the normal squelch in a VHF FM receiver. It's also good for monitoring VHF/UHF mobile-telephone channels in systems where a constant idle tone is transmitted while no call is in progress. The circuit has other applications as a "smart" VOX (voice-operated switch) for transmitters, recorders, intercoms, security systems, remote-base systems, and repeater equipment.

Circuit Description

U1A is a unity-gain summing amplifier, input buffer, and low-pass filter with 3-kHz cutoff. U1A drives U1B, a third-order high-pass active filter with 3-dB cutoff at 500 Hz. We chose high-performance FET-input operational amplifiers so that active filters could use high resistances and small capacitors. The TL084 quad op-amp chip is equivalent to the National LF357.

U1C and U1D are limiter amplifiers with a combined gain of 85 dB. U1D's output is voice-band audio turned into constant-amplitude square waves. The square waves trigger CMOS monostable multivibrator U2. Output of U2 is a train of .33-millisecond pulses, one for each audio cycle. The *average* voltage of U2's output is proportional to the input *frequency*. U2 and the following low-pass filter form a frequency-to-voltage converter, i.e., FM detector, somewhat similar to an automobile tachometer circuit.

Active low-pass filter U3A cuts off at 3.25 Hz, the best compromise between noise-falsing and the rate at which people speak syllables.[2] Note that U3A has no bias network even though the amplifier uses a single-polarity power supply. U2's averaged pulses keep the output of U3A at 5 to 6 volts with normal noise input from the receiver. R17, which sets U2's period, can be varied to keep U3A's quiescent output voltage near the center of its range.

On very quiet channels there may not be enough pulses from U2 to keep U3A properly biased. False detects may occur as U3A's output goes in and out of its linear range. You can inject extra noise or low-level tone into the squelch circuit's auxiliary input to achieve the desired results for your particular application.

U3A's output is ac-coupled to U3B, which amplifies with a gain of 2, and thence to U3C, a unity-gain inverter. U3B and U3C together form a phase splitter with a gain of 2. The phase

splitter provides positive-going outputs for positive *and* negative frequency deviations of the receiver audio.

Comparators U4A and U4B detect the rate-of-change-of-frequency signals from the phase-splitter outputs. If the voltage at the inverting (−) input of U4A *or* U4B exceeds the reference voltage set by squelch-threshold control R30, then the low-going level at the comparators' paralleled open-collector outputs discharges C20 through R34 and D1. The discharge time constant is 10 milliseconds. C20, R35, and comparator U4C form a time-delay circuit which holds squelch open during its one-second period. Each detector output longer than 10 milliseconds resets the timer for another one second. R35 controls length of delay.

U4C's output is the squelch-open signal (active high). U4C turns on hysteresis-switch transistor Q1 (which lights LED2) and activates output-driver U4D. As shown, U4D's output goes high to unsquelch. We used normally-closed relay contacts so that the speaker is enabled when the relay is turned off or if power is removed from the squelch circuit. To reverse the sense of the output, exchange the (+) and (−) inputs of U4D. (Jumpers are provided on the PC board.) U4D's open-collector output can drive a relay in the speaker lead, as shown, or a gated amplifier, analog gate, optoisolator, or TTL or CMOS logic circuit. The comparator output can sink 50 mA maximum.

The squelch is more sensitive *after* opening than before. The sensitivity change is called *hysteresis*. With no hysteresis, the squelch may drop out while someone is talking. If there is too much hysteresis, squelch threshold becomes hard to adjust properly. Detector comparators U4A and U4B have two levels of hysteresis. Positive-feedback resistor R32 prevents comparator oscillation and lowers the threshold slightly during a

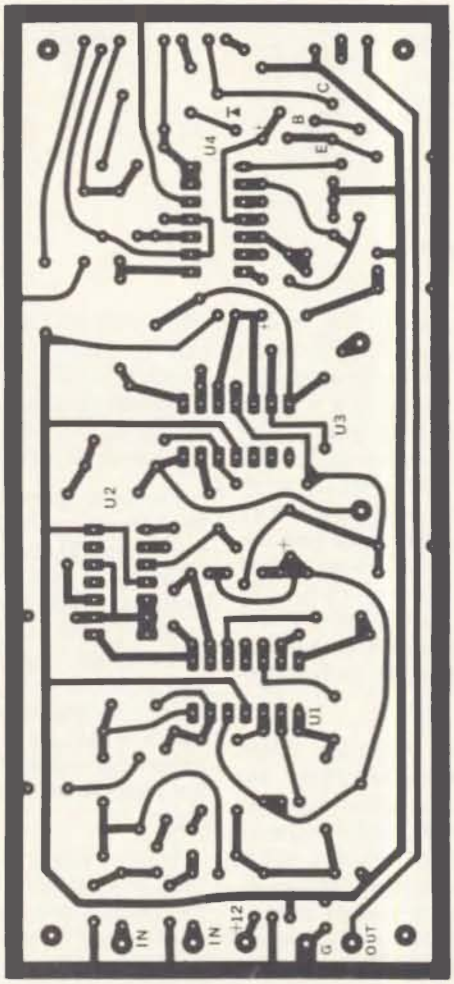

Fig. 2. PC board (foil side).

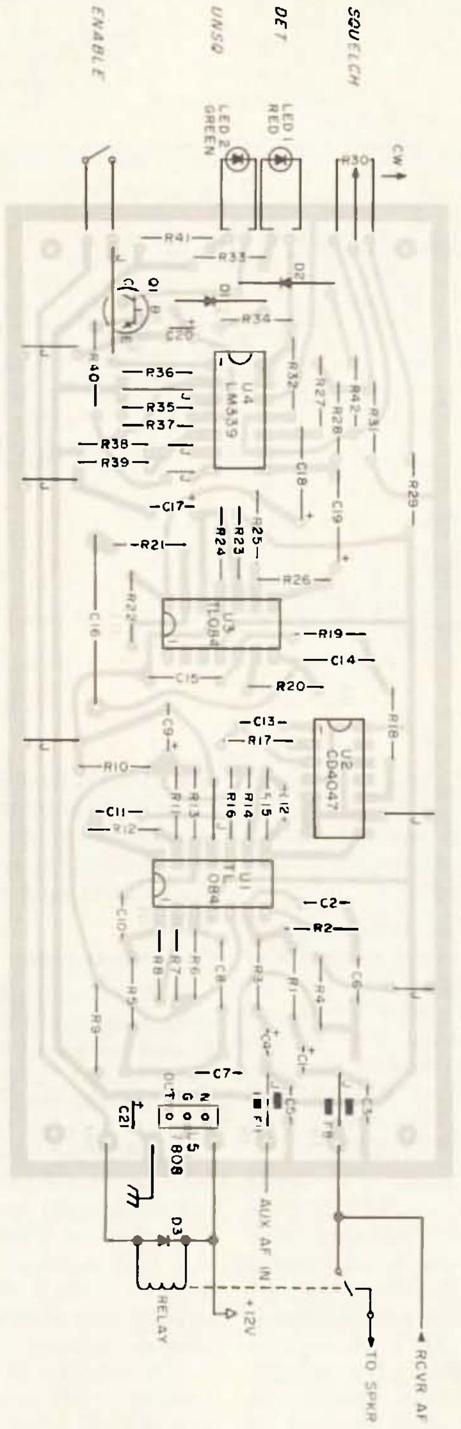

Fig. 3. Component layout.

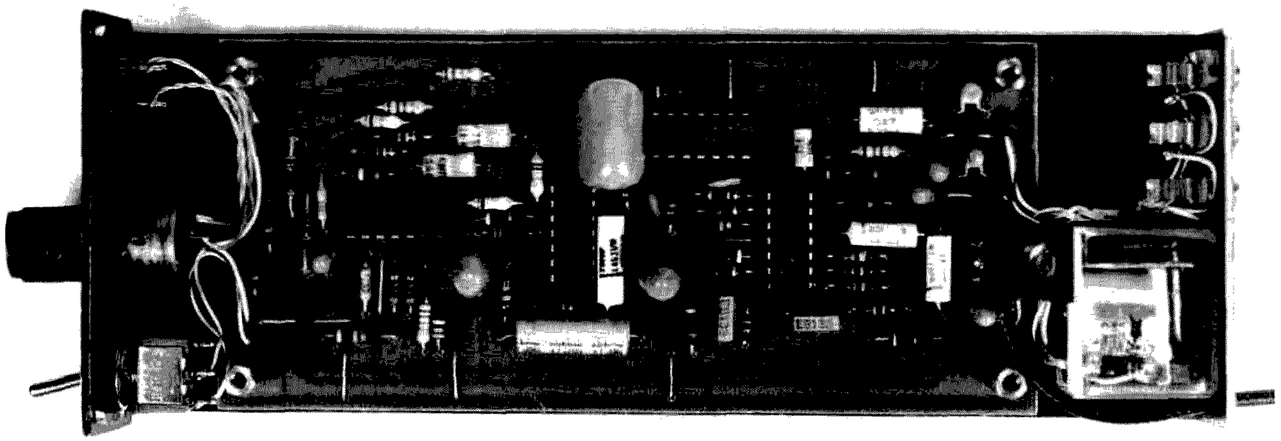

Photo B. Circuit board and chassis detail. The only external connections required are receiver audio, speaker, and 12 volts dc. (Photo by KA9FJS)

detect. Q1 conducts while squelch is open, further reducing the threshold voltage via R42 and D2. R42 determines the amount of hysteresis. The 100k value shown for R42 provides smooth squelch operation.

The circuit uses 25-30 mA plus relay current. The eight-volt-regulator IC, U5, should be used for mobile operation. Otherwise, the entire circuit can run from a well-regulated 12-volt supply. (Omit U5 and add a jumper between input and output pins of U5 on the PC board.)

Adjustment

LED1 lights whenever the detector is active. Listen to a voice signal and adjust the threshold control until LED1 blinks for every spoken syllable, then make fine adjustments as necessary for noise conditions. The *enable* switch allows you to adjust the squelch before activating the relay and allows you to unsquelch without disturbing the threshold setting. Scale markings around the control knob make it easier to reset an often-used level.

Construction

All-new parts cost about $40, using referenced items from Radio Shack and ECG. Resourceful hams can build

the circuit for substantially less.

We built several prototypes on universal printed-circuit cards. The only critical area is U1, where high limiter-amplifier gain can cause feedback oscillation in some layouts. Keep component leads as short as possible. Use 5% tolerance or better for frequency-determining components in active filters. The Radio Shack relay's frame must be insulated from ground. Mounting the relay on a rubber pad quiets its clicking and isolates it from vibration.

Conclusion

Although squelch effectiveness may diminish on very crowded amateur bands, a sensitive, discriminating squelch is very useful for net operations and scheduled contacts, especially with modern digitally-tuned receivers which can be preset to precise frequencies.

This circuit can be a starting point for many experiments. You could, for example, insert an analog delay device between audio input and output. If the delay were longer than the squelch response time, then squelch would open *before* the first spoken syllable reaches the loudspeaker.

Digital techniques could perform the function of the analog circuit described here, perhaps with improvements such as adaptive threshold and program-controlled time constants. We are experimenting with a microprocessor-based voice detector which may be the subject of a future 73 article.■

The Ultimate Fuse

—ac overload protection

Neil Johnson W2OLU
PO Box 585
South Orleans MA 02662

Recently, while working on the design for a new power supply, I managed to blow over a dozen fuses. My regular ham buddy was on a weekend fishing trip, so I kept making the same, simple error. After the trouble was located and corrected, it somehow struck me: There's got to be a better way!

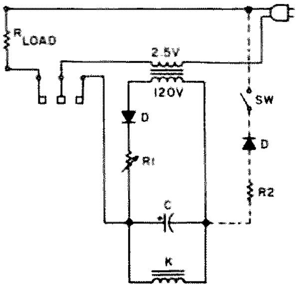

Fig. 1. The early circuity was fairly simple, but half-wave rectification from the 120-volt winding caused the setup to be less sensitive than desired. Added components shown connected with dotted lines are needed to keep the relay locked up after an overload has caused the circuit to be broken. (Note: Relay shown at rest, i.e., non-energized.)

In the past, hams who built their own power supplies could depend on manufacturers to offer several different types of relays, some with manual reset capabilities and some with electrical reset features, but such items are no longer available to the amateur builder. In view of this deficiency, a few years ago I offered a homely solution to the dc overload-relay problem: how to home-brew what you can no longer purchase.[1]

It is common practice for commercial and military installations to provide circuitry to protect their power supplies, both as to input and output. Dc overload relays are properly installed in the output of the rectifier or filter circuits, and ac overload relays are installed in the primary circuits of the various power supplies, and so on. But I had yet to see how an amateur experimenter might put together a suitable substitute for an ac overload relay.

In an earnest effort to devise some sort of simple circuitry for such a need, it came to mind that several factors had to be taken into consideration. The system had to be simple, foolproof, and, above all else, inexpensive. There is no logic in providing an expensive method for the sort of thing which a typical amateur might wish to protect. The setup to be described satisfies all of the foregoing.

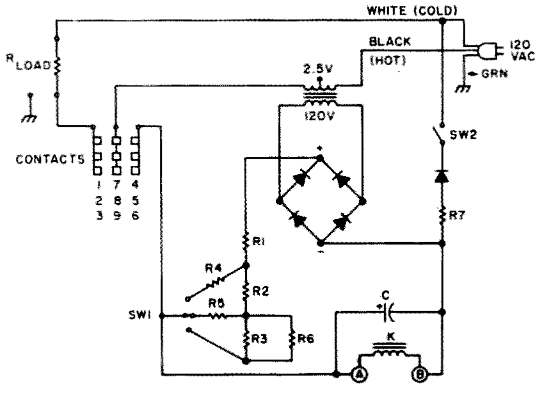

Fig. 2. Final version of overload relay. SW1 selects 2.5-, 5-, or 10-Amp kickout points.

The heart of the protective circuit lies in the utilization of a surplus 24-volt dc relay. These are widely available at low cost. If such a relay can be incorporated into a simple circuit, then we should end up with a satisfactory combination for taking care of ac overloads.

Refer to Fig. 1. Note that we have incorporated a surplus 2.5-volt filament transformer of 10-Ampere rating. Since silicon diodes came into play as substitutes for mercury-vapor tubes, such transformers have become a drug on the market. But a suitable transformer of similar ratings should serve; that is, a low-voltage secondary and rather high current rating.

Preliminary experiments

led me to develop the most elementary circuitry to fulfill the concept. When current is passed through the 2.5-volt winding a current will be induced into the 120-volt winding (now the secondary). After rectifying and filtering, the dc voltage is used to actuate the 24-volt dc relay. The variable resistor, R, can be adjusted to allow various ac currents to pass before the relay will trip and open the ac circuit.

This will not completely suffice, however, since the relay will buzz back and forth between on and off unless some form of lock-up is provided. The added components, shown by dotted lines, attend to this function. Lock-up is obtained with lower current than is required for pull-in, and simple half-wave rectification will serve. Reset is furnished by opening the switch, which is normally closed.

The system that finally evolved is shown in Fig. 2. The full-wave bridge rectifier furnished more voltage than the original half-wave circuit and allows the relay to trip out at a lower current. In a thorough search for a relay of better suitabilities, over a dozen relays were checked out experimentally. Finally, it was decided to opt for a relatively sensitive unit which has the added advantage of having three sets of contacts, all rated at 10 Amperes. To be on the safe side, these are wired in parallel.

My thoughts then were directed to the feasibility of obtaining a suitable variable resistor, in order to enable the relay to actuate at various current settings. Easier said than done!

The three principal calibrating resistors are used in place of a "nice to have" 3000-Ohm, 10-Watt wirewound potentiometer. The 5-Watt, 1000-Ohm size is a fairly common item in all stores which cater to radio and TV servicemen. Additional resistors were added to cause the setup to kick out at 2.5, 5, and 10 Amperes. This 4-to-1 range is in line with what the commercial makers of such relays—Westinghouse for example—design into their products.

Other design factors worth mentioning are:
(a) The 100-uF electrolytic capacitor seems to be about right in this setup. A lower value may cause the dc relay to buzz, and a higher value can cause a time delay to take place—definitely undesirable in any form of protective circuitry where high power is involved; and (b) Avoid carbon resistors in the 1000-Ohm positions. Careful checks show that a 1000-Ohm, 2-Watt carbon resistor will be dissipating 1.6 Watts or 80% of its full value. This will cause upward change in the resistance, and, indirectly, "calibration creep" in the finished instrument.

Random thoughts at this juncture: Others have asked me whether simpler devices, such as the thermal overload units commonly found on the back of TV sets, would suffice. These have been tried and their use cannot be justified since the time delay is intolerable where an expensive unit requires protection. Personally, I almost lost a very nice Powerstat® while attempting to live with such protection.

Perhaps solid-state devices might be designed to furnish the same function? I would be disinclined to depend upon such a setup in view of the relatively high-voltage spikes which are encountered when a highly inductive component—such as the power transformer in a large amateur rig—needs to have its primary circuit interrupted. For that reason, I chose 1000-volt silicon diodes, type 1N4007, for service in this unit.

So we have an ac overload relay which is simple, inexpensive, and dependable. Furthermore, it can be calibrated to kick out at several different amperages at the flick of a switch. I have yet to see such a simple item described in print, and I thought it would be nice to share this knowledge with other members of the amateur fraternity. So, why not try this out and experiment at ease, without blowing box after box of fuses?

All of the foregoing calibrations were obtained with ac loads consisting of non-inductive heater coils. If your circuit to be protected is highly reactive, you may find the relay kickout points to be slightly different. ■

Parts List

T— 2.5-volt, 10-A filament transformer
D— all diodes type 1N4007
C— 100 µF, 35 volts
S1— Rotary switch with 3 positions
S2— Momentary-contact switch, wired for normally-closed operation (Radio Shack 275-619)
K— Potter & Brumfield type KUP 14D15 (Fair Radio Sales, Lima, Ohio, $2.50)
R1-R3—1000 Ohms, 5-Watt, wirewound
R4, R5—330 Ohms, 1-Watt
R6— 15k Ohms, 1-Watt
R7— 2700 Ohms, 2-Watt
Small cabinet or chassis, 3-wire ac cord, and 5-way output terminals

RF ANNOUNCING

RF PRODUCTS announces production of 5/8 wavelength VHF telescoping antennas for 144-148 MHz (2M), 152-174 MHz and 220-225 MHz (1¼M). These new antennas are intended for use on hand-held and base station transceivers. They are available with BNC connector, 5/16-32 stud, or PL-259 connector. A telescoping brass nickel-plated nine section radiator is used for lighter weight and less RF junctions than previously available 5/8 wavelength antennas. Maximum gain is acheived by the combination of a base spring for whip protection and a tuned matching network for minimum VSWR. Minimum 2-meter bandwidth for 1.5:1 VSWR is 3.5 MHz. Overall length with BNC connector is 45¾ inches (1162mm). The BNC connector and 5/16-32 stud models are intended for hand-held transceiver (HTs) use and the PL-259 model which includes a type M359 right angle adaptor is intended for direct rear mounting on base station transceivers. Suggested list price for all models is $19.95 the most popular of which are listed below.

Multi-Purpose Peak Adapter

—don't settle for being average

This adapter was originally designed to be used with a Bird 43 wattmeter, using the standard plug-in elements; however, this same unit can be modified for use with almost any rf detector or swr bridge. Circuits can be easily added to provide an adjustable peak output indicator and/or an alc output for transmitter control. The peak adapter circuit also can be used with an FM receiver as a peak-deviation meter. Easily-obtainable parts are used and while I built mine in a separate box, you might be able to build it into your meter enclosure. The ICs must be kept away from high rf levels, however. The peak adapter circuit is shown in Fig. 1.

The unit must be powered from a bipolar supply of ±6 to ±15 volts or from a pair of 9-volt batteries. If extended use of the adapter is anticipated, the ac supply shown in Fig. 2 should be used. Regulation is not totally necessary, but does ensure minimum offsets and prevents transients from entering critical circuits.

The main purpose of the peak detector circuit is to overcome the main fault of a meter when trying to indicate peaks: the mass of the movement damps the response time such that variations of the applied current are *averaged* out. The more sensitive the movement, the worse the damping effect. The Bird 43 uses a 30-μA movement and most swr bridges use a 50- to 200-μA meter.

Even with the peak detector, the meter will still

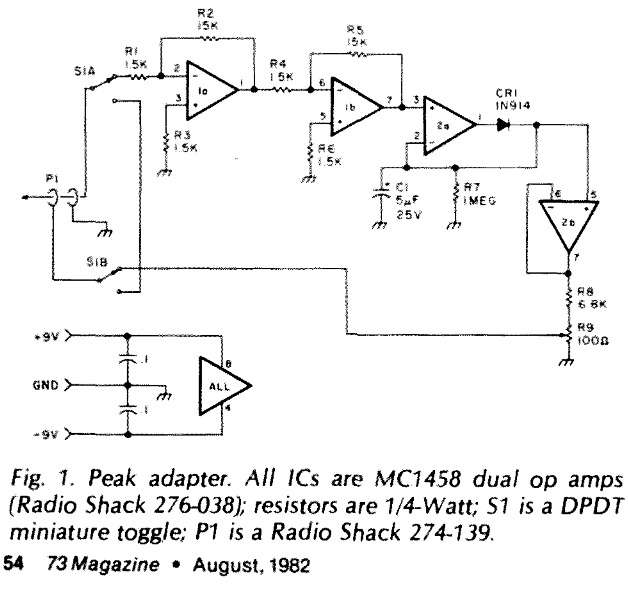

Fig. 1. Peak adapter. All ICs are MC1458 dual op amps (Radio Shack 276-038); resistors are 1/4-Watt; S1 is a DPDT miniature toggle; P1 is a Radio Shack 274-139.

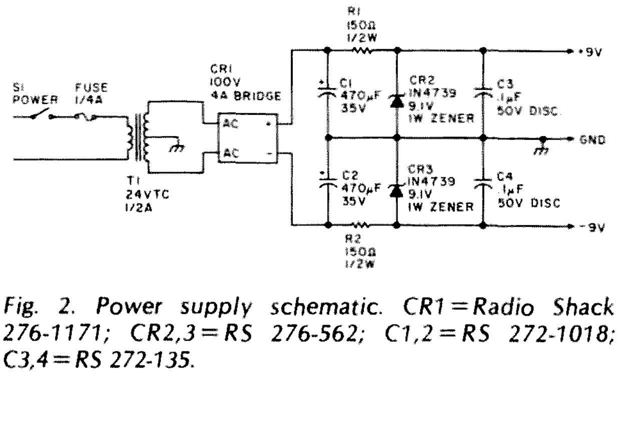

Fig. 2. Power supply schematic. CR1 = Radio Shack 276-1171; CR2,3 = RS 276-562; C1,2 = RS 272-1018; C3,4 = RS 272-135.

take the same amount of time to respond to its highest level, but the circuit has a long enough time constant to ensure that the pointer will remain at the peak level long enough to be observed. The Bird 43 elements contain a half-wave detector (+ output) and a small capacitor to bypass the rf. Internal resistance of the 30-μA meter is 1500 Ohms, so to ensure proper linearity, the input of the peak adapter presents a 1500-Ohm load to the element.

Circuit Description

The first two stages are standard inverting dc amplifiers. Each stage has a gain of 10 for a total of 100. Thus, a full-scale input level of 45 mV results in an output of 4.5 V dc. IC2A is a unity-gain half-wave detector. The diode's placement in the feedback loop eliminates the error due to its 600-mV drop. The input impedance of IC2A is high, so the discharge time constant is essentially determined by R7. The output impedance of IC2A is less than 100 Ohms, so the charge time of C1 is almost instantaneous. IC2B is a unity-gain follower configuration used to isolate the load from C1. Amplifying the input signal by 100 ensures overcoming any low-level non-linearity in CR1. R8 and R9 divide the output back down to a level required to feed the meter.

Fig. 3(a) shows the original circuit in the Bird 43. The meter connects directly to the output of the directional coupler through a length of coax cable. The length is not critical and is supplied as a convenience to permit remote mounting of the directional coupler.

Fig. 3(b) shows the jack added to the Bird meter to permit connecting the peak adapter. I mounted the jack on the right side of the case. (Remove the meter movement before drilling the 3/8" hole!) The jack is a 3-conductor, ¼"-type with shorting contacts (Radio Shack part number 274-139). The shorting contacts connect the meter to the coupler when the remote plug is removed, so no switch is necessary. Use the "ring" connection for the meter and the "tip" for the coupler output. Break the connection at the positive lug of the meter. Even though the jack is grounded to the case, it is a good idea to run a wire from the negative meter terminal to the "sleeve" connection of the jack.

Calibration is easily accomplished by connecting the meter between the transmitter and a 50-Ohm load. Measure the power output with a steady carrier (preferably at least half-scale). Switch on the peak detector circuit and adjust R9 for a reading of 1.4 times the first reading. The meter now is calibrated to read peak power output (with a load impedance of 50 Ohms).

PEP output is defined as the peak-to-peak level of the output signal. It is not practical to have the meter read this since it would be necessary to change to the next higher element. R9 could be adjusted so the PEP would be read on the next higher scale using the same element; however, damage to the element could occur since it would be used outside its normal range.

When observing a voice-produced SSB signal, you will have to talk for several seconds to allow time for the meter movement to respond. A longer "hang" time can be obtained by increasing the value of C1.

The output of an swr bridge is similar to the Bird elements but the load impedance is usually higher. To use the peak detector with an swr bridge, or a

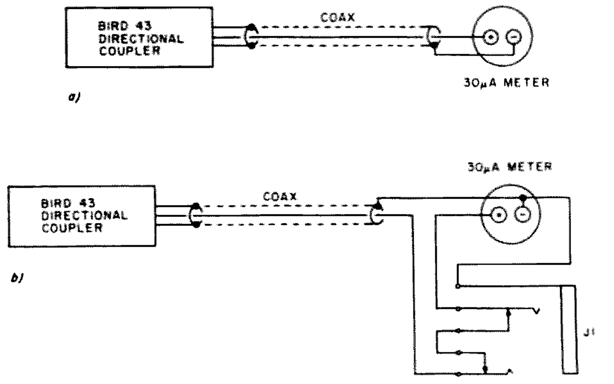

Fig. 3. (a) Original Bird 43 hookup. (b) Modified hookup using Radio Shack 274-277 for J1.

detector like the one in the Heath Cantenna®, change the circuit of IC1A to that shown in Fig. 4. You will have to calibrate the meter at several different power levels. The dc output voltage of a bridge detector, and the detector in the Cantenna, drops with a decrease in frequency, so calibration at several frequencies in each band is desired. Calibration must be done with the aid of a borrowed wattmeter, an rf ammeter or voltmeter, or a wideband scope that has a vertical amplifier response flat to at least 30 MHz.

When using the peak adapter with a device like the Cantenna, you will have to furnish a meter for the adapter. Any movement up to 5 mA can be used or a VOM on the 2.5- or 3-volt dc range. Just be sure that the VOM you use will not detect rf by itself. If you use a 1-mA meter, you can eliminate R9 and use a 3.9k resistor for R8. Calibration can be done with R19. A typical swr bridge circuit is shown in Fig. 5.

At a power of 100 Watts rms into the Cantenna, I obtained the following read-

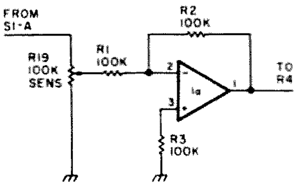

Fig. 4. High-impedance peak adapter.

ings from the Cantenna's detector:

Band	Dc Volts
160	0.8
80	1.0
40	1.4
20	2.0
15	2.5
10	3.0

The circuit of Fig. 6 is a peak-indicator driver with adjustable threshold control. R10 is adjusted with a steady carrier to light the LED at the desired power level.

Alc voltage can be applied to most mixers or intermediate stages in a transmitter to reduce the rf level before the output stage is driven into the non-linear region. The alc voltage can be developed by adding the circuit in Fig. 7. It even can be useful for transmitters that already have alc because gain reduction can be

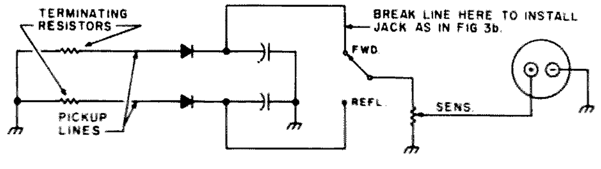

Fig. 5. Typical swr bridge.

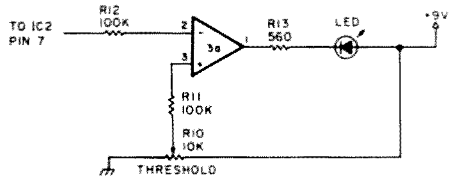

Fig. 6. Visual peak indicator.

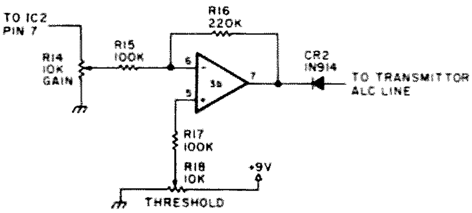

Fig. 7. Alc detector.

had at a lower level. (Many transmitters develop alc voltage when grid current is drawn, at which point distortion is already occurring.) With R18 at the ground end, alc will be developed as soon as there is rf input. R14 determines the amount of voltage output. Increasing R18 towards +V permits a higher rf level before alc starts to develop. CR2 keeps any positive voltage from reaching the alc line.

Both the circuits of Fig. 6 and 7 can be connected to IC2 simultaneously without any interaction. Again, change the value of C1 if you wish to change the time constant. Most likely, you will want to reduce C1 to 0.2 to 0.5 μF for alc purposes. A switch may be added to Fig. 1 to select various values for C1.

Another use for the peak detector circuit is to use it in conjunction with an FM receiver as a peak-deviation meter. Using the Fig. 4 modification, connect R19 to the output of the discriminator through a 0.1-μF capacitor. Calibration can be done best using a signal generator with calibrated FM modulation. If C1 is switched out of the circuit, the meter will then read average deviation. This may be useful to show how much the transmitted audio is limited in the peak clipper. In any case, the readings will only be correct if the received signal is full quieting. A scope may be connected to the output of IC1B for viewing the audio signal.

If you have looked at the proposed rewrite of the amateur rules, you noticed that the FCC is trying to come up with a different way to determine transmitter power, other than the present dc-input method. This peak adapter can be an invaluable aid, should power determination need to be in terms of peak power. Personally, I would like the rules to be changed to power output measurements, as is done commercially. This could then permit less efficient transmitters to run at a higher input power. We also would have a better idea of the efficiency of our equipment which would indicate when the finals are getting "soft."

This circuit can make your wattmeter into a more useful instrument at a fraction of the cost of a ready-made peak-reading unit and serve other purposes as well. ■

TERMINALL

apple* + TRS-80*

TERMINALL is a hardware and software system that converts your personal computer into a state of the art communications terminal. Terminall features simple connections to your computer and radio plus sophisticated and reliable software.

Simplicity

TERMINALL was designed from the outset to be easy to connect to your radio and easy to use. Plug into your receiver headphone jack and copy Morse Code or radioteletype (RTTY). Plug into your CW key jack and send Morse Code. Attach a microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.

The software is loaded into your computer from disk or cassette. Enter your callsign and the time and you will start receiving immediately. No settings or adjustments are necessary to receive Morse Code, it's fully automatic -and it works! You may type your message while receiving or transmitting.

You will be on the air, receiving and transmitting in any mode, in minutes. As we said, TERMINALL is simple.

More for your money.

■ TERMINALL has the RTTY terminal unit -demod and AFSK- built in. This results in a lower total cost.

■ **Fantastic Morse reception.** Six stage active filter demodulator copies the weak ones. Auto adaptive Morse algorithm copies the sloppy ones. Received code speed displayed on status line.

■ **Outstanding documentation.** Professionally written, 90 page user manual contains step by step instructions.

■ **Built in, separate, multi-stage, active filter RTTY and CW demodulators.** No phase lock loops. RTTY demodulator has 170 and either 425 or 850 Hz shift keyboard selectable - and uses either the panel meter or scope outputs for easy tuning. Copy the weak ones. Copy the noisy ones. Copy the fading ones.

■ **Built in crystal controlled AFSK.** Rock stable for even the most demanding VHF or HF applications. A must on many VHF RTTY repeaters.

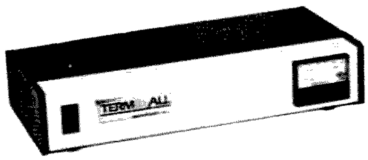
■ **Built in 110 or 220** volt AC power supply.

■ **Built in parallel printer driver software.** Simply attach a parallel ASCII printer (e.g. the EPSON MX 80) to your printer port to obtain hardcopy in all modes.

■ **Multi level displays** allows examining and editing of historical text.

■ **Word wrapping,** word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, multiple user defined WRU, transmit delay (fixed, none or auto adaptive), break mode and more!

■ **The all-in-one TERMINALL design** makes it great for use on HF or VHF, Ham, Commercial, SWL or MARS! SWL's: TERMINALL may be jumpered for either 425 or 850 Hz reception to copy news and weather services.



System Requirements

TERMINALL T1 Communications terminal for the TRS 80 Model I. Requires a Model I TRS 80, 16K RAM and Level II BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T3 Communications terminal for the TRS 80 Model III. Requires a Model III TRS 80, 16K RAM and Model III BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T2 Communications terminal for the APPLE II. Requires an APPLE II or APPLE II PLus with 48K RAM and disk. Software is provided on disk in DOS 3.2 format. Use MUFFIN utility to convert to DOS 3.3 format. Includes software on disk, assembled and tested hardware and an extensive instruction manual. **$499.**

The communications terminal that does it all!

The $100 TVRO Receiver

—Satellite Central, part VIII

Dwight "Rex" Rexroad with his Cheap Trick receiver.

Stephen Gibson
PO Box 38386
Hollywood CA 90038

"See first run movies, sporting events, and nightclub acts as secret network feeds!" That's the sort of ballyhoo you read about satellite television nowadays. But the price for even a kit setup can run sky high! The only way to cut the cost is for you to do it all yourself.

But those build-it-yourself pitfalls can leave you wishing you'd never tried. For one thing, you're on your own with only plans that are vague or, even worse, a set of PC boards that won't work. So, being first on your block seems to carry its own set of problems. What you need is a "Cheap Trick"!

In the December, 1981, "Satellite Central," I wrote a brief overview of TVRO receiver design. If you priced some of the components, you know that a receiver, especially a dual-conversion job, will cost $500 to $700 to build. And, if you want real quality you'd better plan on spending more. So how can something any good cost less? As a matter of fact, just a voltage-tuned oscillator (VTO) runs a hundred bucks! So who's kidding whom?

But hold on there. Just when you think it isn't possible, along comes a very clever engineer like Dwight (Rex) Rexroad who does it with a flair that shows that hobbyist thinking and ingenuity hasn't stagnated after all. "The secret here," says Rex, "is to make the design non-critical and to use parts that anyone can find with ease. Nothing in this design is weird. Everything is off

the shelf." Out of Rex's unique approach comes "Cheap Trick," the ham's answer to a TVRO receiver you can build for under $100!

Cheaper Is Better

Look at the diagram in Fig. 1(a); Rex downconverts all twelve transponders on a satellite (3.7 to 4.2 GHz) to the 500- to 1000-MHz region where he can use cheaper components. He uses a fixed-frequency local oscillator (LO), a mixer, and a broadband amplifier, all of which may be mounted at the dish in a small box. The advantage to this arrangement is that the lower-frequency signals can be passed into your house via RG-59 or RG-6 rather than expensive cable needed for piping 4-GHz signals.

No tuning is done in the first conversion—see Fig. 1(b). Instead, tuning is applied at the second conversion by another cheap trick, a UHF TV tuner. The saving is enormous, especially since the tuner needs very few changes to make it pass 30-MHz-wide signals to a 70-MHz bandpass filter and intermediate frequency (i-f) amplifier. Despite its reduced performance at 70 MHz, Rex uses a typical TV i-f IC, the MC1350. It's a logical choice for the i-f amplifier because of its low price and easy availability. Razor-sharp tuning is easily accomplished using just two op amps with a solid afc thrown in to boot.

The amplified 70-MHz i-f signals are halved to 30 MHz by a divide-by-two circuit and applied to an MC1357 quadrature detector IC which, with suitable input, can deliver pictures that may exceed in excellence those of a PLL-type detector. The detected video is clamped and de-emphasized before output to your TV monitor or modulator. The sound demodulator uses circuitry similar to that found in most television sets.

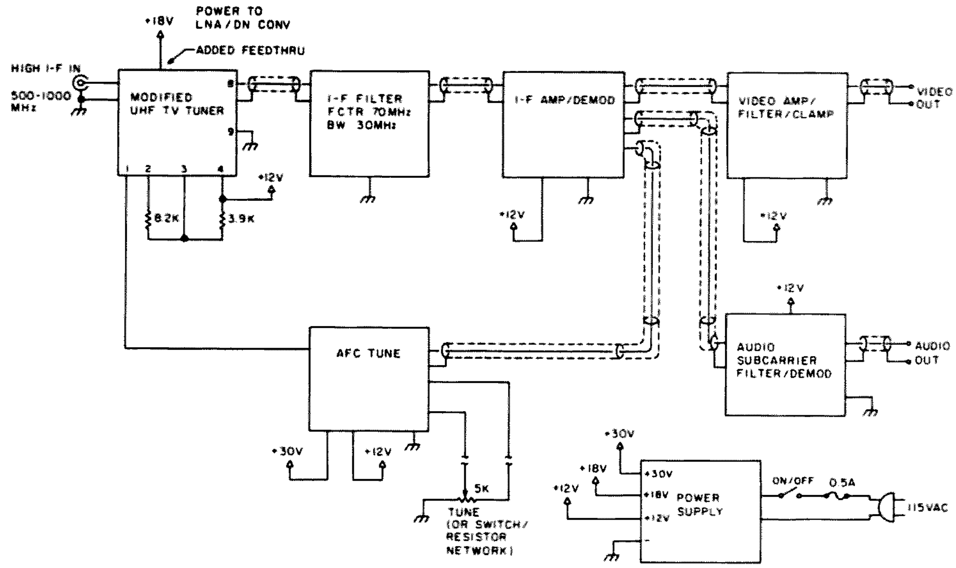

Fig. 1(a). Block diagram of the Cheap Trick receiver.

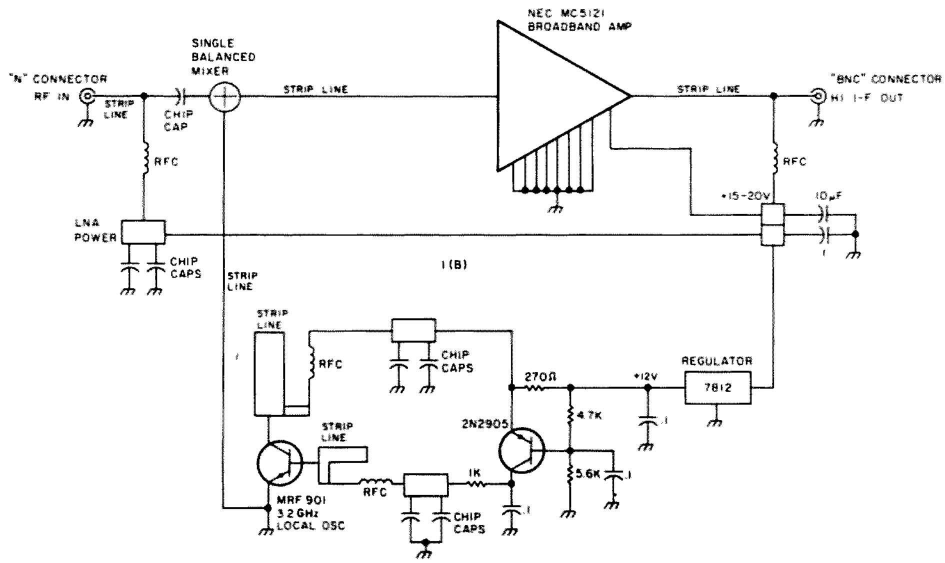

Fig. 1(b). First stage of the receiver downconverter, including balanced mixer and local oscillator.

Power Supply and Downconverter

This month, we'll delve into the power supply and clever downconverter design and save the baseband circuits for next month. It should be remembered that this project is labor-intensive. If you just want to watch satellite television, then you really should buy a receiver rather than fiddle with the "Cheap Trick." Some of the techniques used here will surely challenge your experimenting abilities.

According to Rex, "The power supply is not quite typical . . . but close. I use a 26-volt, 1-Ampere transformer that is center-tapped. This is a common transformer. Radio Shack has them. [Rex needed 30 volts for tuning and took the easy way with an LM317 adjustable voltage regulator—see Fig. 2.] I found that bypassing the LM317 got rid of a lot of noise, especially since we are dealing with the tuning voltage where noise could easily FM your tuner! It's clean as a whistle."

The really clever technique used here is to raise the centertap to get about half the voltage (18 volts) to feed the LNA-downconverter combination. A 7812 regulates it down to 12 volts to feed the rest of the receiver. While Rex admits this is not an optimum design bal-

ance-wise, it offers something more important: It's cheap!

Looking now at the downconverter in Fig. 3, Rex built the whole unit on a piece of double-sided 1/32" Teflon™ fiberglass. In true one-of-a-kind experimenter fashion, he used only an X-acto® knife to cut out the prototype. You can, too. The board is only 4 inches long, so the input and output connectors are all that are needed to attach the board to the top of a sealed metal case.

The circuit includes a dc block so that both the downconverter and the LNA can receive their supply voltage through the signal coax. Beginning at the input, Rex uses a type-N connector since that's about the only thing that works well at these frequencies. An rf choke . . . which is nothing more than a short piece of wire at 4 GHz, feeds dc to the LNA.

"We do a little bypassing with two chip caps—a 4.7-pF and a .001-mF work pretty well at these frequencies. I bypass darned near everything because stability is very important. Especially when you home brew," he says.

"I used a fixed-tuned MRF-901 for the oscillator so that I could save big bucks right there! The real credit for this stable design belongs to BBC engineer Steve Birkill. The oscillator runs at 3.2 GHz (downside injection) and is easily set by trimming the length of the baseline with a knife.

"I used a 7812 voltage regulator, but a 78L12 would also work since we need only about 15 mA. The 2N2905 is a PNP transistor that acts as an active bias for the oscillator. It's the negative feedback loop that makes this trick work. In fact, it may be more stable than expensive prepackaged oscillators if you use good construction technique. And don't think you're locked into a 2N2905. Any other silicon PNP of the same beta should work just as well."

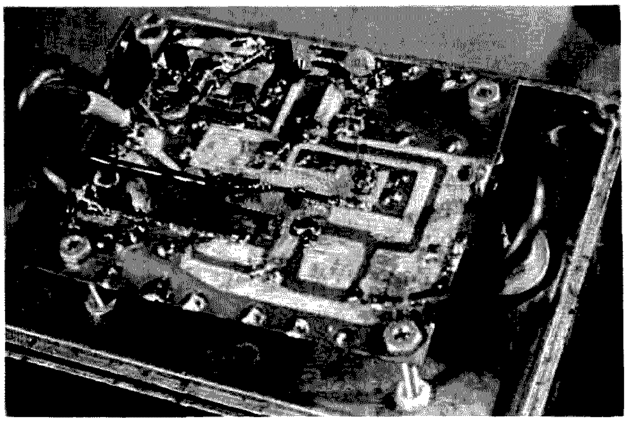

Fig. 3. The mixer, MRF-901 oscillator, and broadband amplifier fit on a homemade PC board.

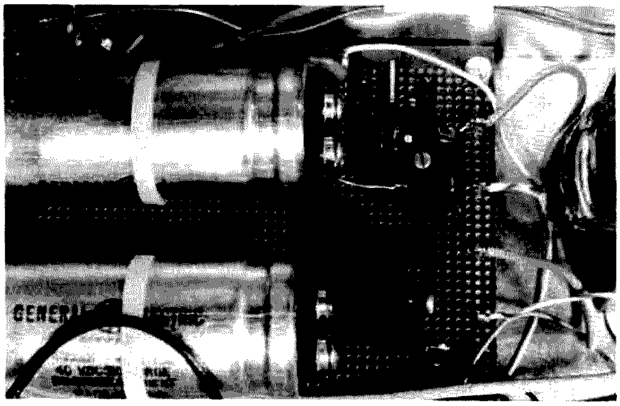

The oscillator will come out low in frequency using the layout size in Fig. 4. That way, you can simply use a knife to chop away enough trace to put it right on. The line from the oscillator is a 50-Ohm stripline. Both the oscillator and input signal feed a balanced stripline mixer which has about 7-dB insertion loss depending on the diodes. Now, rather than use a $55.00 mixer, Rex literally chose to roll his own. He uses HN-1 diodes at about $2.00 each. Quite a saving! It really doesn't matter how you install the diodes; just be sure they are backwards or you'll have a problem. If you use the popular MBD-101 diodes, you may have to deal with slightly more noise out of the mixer. This may not be a problem if you use a large dish and a commercial LNA.

The NEC MC5121 broadband amp is the most expensive part of the whole receiver. It costs about $13.30 from Alaska Microwave, a *73* advertiser. Kick in another 25 cents and you can get the spec sheets, too. The MC5121 will give you about 20-dB gain, so the overall converter gain is about 14 dB not counting coax losses. Either a BNC or type-F connector will work on the output since the signal is now running somewhere between 500 and 1000 MHz. On a typical system, you can tolerate about 15-dB loss from the coax feeding the baseband unit. The +15 to +20 volts of power for the converter is tapped off the output coax with a 6-turn choke and some dc bypassing. There is no coupling capacitor on the MC5121 since it has its own internal caps.

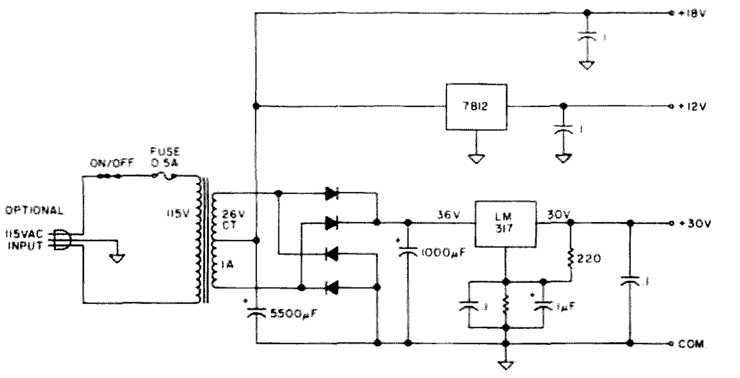

Fig. 2. The power supply furnishes +30, +18, and +12 volts dc.

Making It Work

Probably the hardest part of this project will be acquiring the parts. Yes, you *can* do it for less than $100. In fact, Rex built his for $75.00!

Dropping down in the scale of hardness, we come to troubleshooting. According to Rex: "A spectrum analyzer helps. Use a micro-

wave frequency counter attached to the hybrid to tune the LO. Not everyone has one, so I suggest you simply apply power to the unit and tweak the oscillator until the bottom frequency corresponds to transponder one. You'll need a dish and an LNA that are working to do it.

"One thing that's nice: Being off 100 MHz in either direction will get you in the ball park enough to trim it up. Of course, having a friend with another TVRO always helps."

It is possible that the LO will not be stable or, worse, may not start at all. In that event, Rex suggests you move the shorting strip seen in Fig. 5. Do a tack-solder job. You may find a region where the oscillator is operating on many frequencies at once. It makes for rotten pictures, so move the shorting strip to cure the problem. Trial and error are the only ways to do the trimming without an analyzer.

New Life for UHF Tuners

Once the signal is converted to the 500-to-1000-MHz range, it is fed down the coax into the UHF tuner. Use top-notch RG-59 or better. No CB stuff. Rex used a Mitsumi UES-A55F which he bought at a swap meet for five bucks. See Fig. 7. Various mail-order houses carry this model for something like $25.00. If you do some scrounging for other parts used in this project, you still can build Cheap Trick for less than $100.

Now, most tuners have a narrow bandwidth. So you must modify yours to pass 30-MHz-wide FM. Not all tuners can be modified, so you should try to track down this particular model. On the other hand, if you've stayed with us this far, you can probably handle anything that comes your way!

As a rule, the i-f output stage is the culprit. See the "before" and "after" modification circuits in Figs. 8(a) and 8(b). According to Rex, "I replaced the final stage impedance-matching network with a broadband transformer wound on a ferrite bead. Amidon 101-43 beads work pretty well. I used them everywhere in the project."

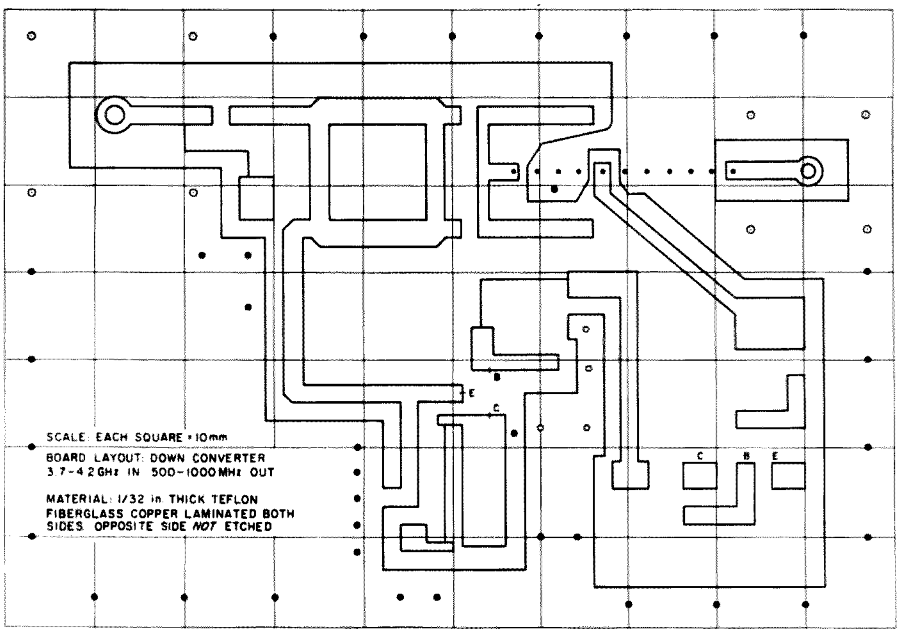

Fig. 4. Circuit board layout for downconverter.

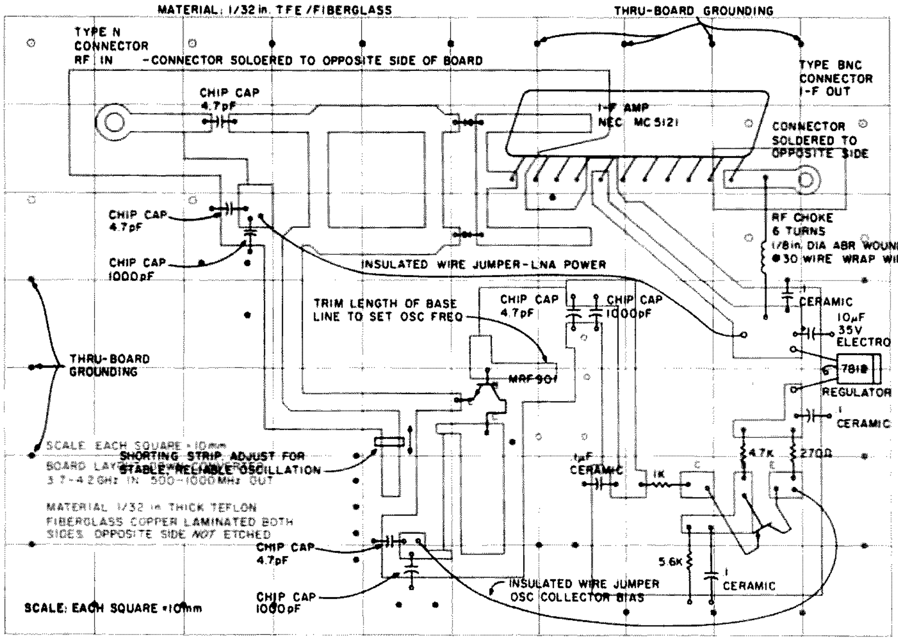

Fig. 5. Parts placement for downconverter.

The input stage should also be modified for a coax input. Some models of the Mitsumi already have a 75-Ohm input. "But if you were stuck with a 300-Ohm model," says Rex, "just look for the place on the board called L1 which was designed for a 75-Ohm link. You can couple to it with a little ceramic capacitor so you can use a 6-turn choke to provide a dc block to feed the coax power for the downconverter and LNA. You'll need to drill a hole in the tuner for this feed. I used a feedthrough cap so that I'd have a place to hook it.

"After these two mods, the bandwidth of the tuner should be about 45 MHz, and it will just cover the

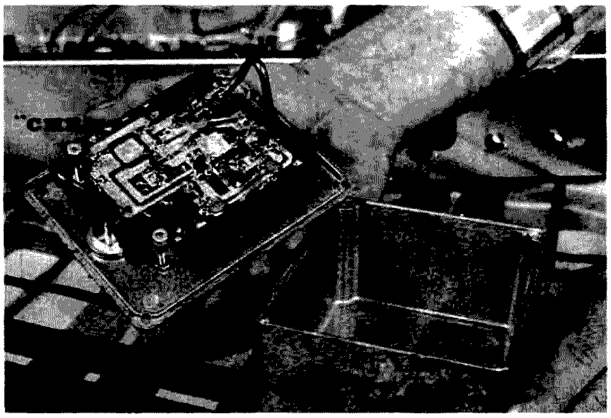

Fig. 6. The completed downconverter is housed in a watertight box. The PC board is held in place by the input and output connectors. A heavy dose of rubber cement will make a good seal.

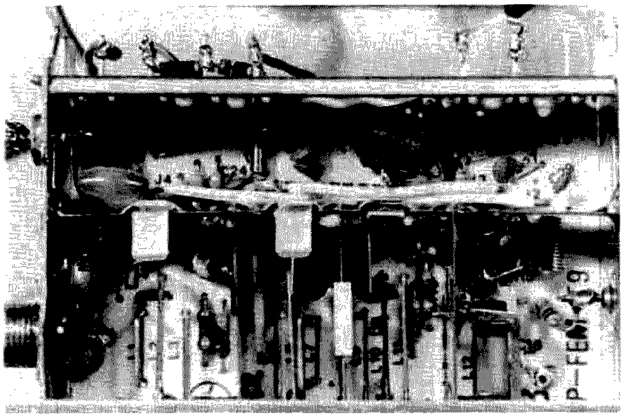

Fig. 7. A Mitsumi UES-A55F UHF tuner acts as the second converter with only two mods. The i-f output coil is replaced with a hand-wound toroid. Also, the input matching network is easily converted for 75-Ohm input. Mount the tuner inside the receiver chassis.

tuning range of all the input signals (500 MHz) with a little to spare. Here is where you must tweak the LO in the downconverter so that you get all transponders over the range of the UHF tuner. It's harder to say it than do it, despite the fact the tuning diodes don't give you much more than the needed 500-MHz range."

Rex suggests, "If you just drop one transponder, then diddle the tuner coils. But if you drop two transponders, you'll need to trot out to the LO/downconverter at the dish. You may have a fellow ham with a frequency counter in this range which should make the whole process very simple."

The tuner agc bias should be about 8 volts. The resistors seen in Fig. 1 form a suitable voltage divider. Eight volts is maximum gain.

Next Month: Part Two

After the tuner comes baseband processing, which I'll cover next month. Rex uses some clever ideas to make this last part of the project look easy. In the meantime, start hunting for parts. ■

VUM: Volume Units Meter

—makes measuring decibels easy

Have you ever wondered if the audio filter in your CW receiver is really as sharp as it is supposed to be? What's the frequency response of your stereo amplifier? How much insertion loss do you get when you stick that audio filter into that line? What's the trouble in that malfunctioning audio amplifier?

If you're a good troubleshooter, you can answer most of those questions with a scope, an audio oscillator, a VOM, and a calculator, but you can't do it either quickly or easily.

But a handy little device has been sitting on my bench for years which provides the answers quickly and accurately. It gets almost as much use as the VOM and a lot more use than the grid-dipper, and it costs very little to build.

Let's call it, affectionately, the V-U-M, for lack of a fancier term. Some electronics manufacturers make similar instruments which they call a "gain meter," and they have a very fancy price.

Basically, the VUM is an audio amplifier which has a calibrated step attenuator on the input and an audio voltmeter calibrated in decibels on the output. The meter itself is commonly seen on audio equipment of all kinds, such as good-quality tape decks, audio consoles, and such, and it goes by the name of "VU meter."

That's because it was originally devised for the broadcast industry to monitor "volume units" of complex voice and music waveforms so that audio input to an AM transmitter could be held within reasonable limits by the audio engineer "riding gain" on the program. In that sort of situation, one "volume unit" only approximates one decibel. But when sine waves are used, as they are in virtually all applications of the VUM, one VU exactly equals one dB.

These meters often can be picked up on the amateur market or at hamfests for a buck or two. They're available from most parts houses for anywhere from $6 to as much as $125, depending on how big they are and how fancy they get. Mine was rescued from a lightning-damaged Heath phone patch.

When using the VUM to solve bench or design problems, it is important to understand something about that interesting little animal, the decibel. It is a unit of measurement of power, voltage, or current, but you can't stick a VUM probe into an amplifier and say, "Ah-ha! It reads one dB!" That's like spotting a hitchhiker on the road and exclaiming, "Ah-ha! He's gone about halfway!"

Halfway from where to where?

A decibel is a measure of comparison. It is a ratio. It is used to state the difference between one level of energy and another.

It is also a rather com-

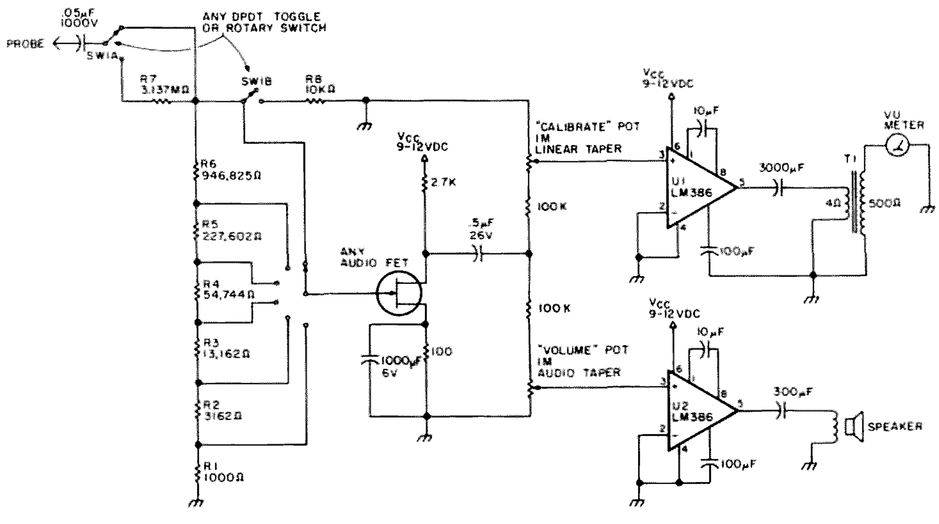

Fig. 1. The VUM (volume units meter), or calibrated audio dB meter.

plex little animal. It is not linear; it is exponential in nature. If you increase your transmitter output from 10 Watts to 20 Watts, the difference is 3 dB. If you increase it again, from 20 Watts to 40, the difference is again 3 dB. Ten Watts to 40 Watts is 6 dB, or two 3-dB steps.

If you increase line *voltage* from 120 volts to 240 volts, however, the increase is 6 dB. The basic formula for determining the dB difference between two *voltages* or between two currents is: dB = 20 log V2/V1.

Now, let's have another look at the VUM, this time in a little more detail. It is a convenient package of several different units:

- A voltage divider resistor string in which each tap on the divider provides 10 dB less signal than the one above it.
- An audio amplifier whose input is taken from the taps on the voltage divider and which drives the VU meter.
- A separate audio amplifier to let you hear what you're measuring.

Additionally, you will need a variable-frequency audio oscillator with adjustable output level. This easily can be built into the VUM as an integral part of the same package if you don't already have such an oscillator. It can be a fairly simple oscillator, covering the range from, say, 50 Hz to 20 kHz, built with ICs. But there are plenty of construction articles about these units and I won't get into that project here.

Essentially, the audio oscillator provides a tone of measurable strength and approximately-known frequency and the VUM measures what happens to that tone as it passes through amplifiers, filters, attenuators, and other exotic devices used by hams and audiophiles.

In my VUM (Fig. 1), the audio amplifiers are LM386 IC chips (available from Radio Shack for about one dollar each), which put out a potent little 400 mW and have a very wide frequency response, from well below the audible range, well into the superaudible. Other amplifier chips such as the LM2277, LM1877, or LM377 also can be used. They provide two 2-Watt amplifiers in the same chip.

One 386 drives the loudspeaker for aural monitoring. The other drives the meter. An even better meter driver might be constructed from an op amp, such as a 741 or TL081, which could drive the meter directly without help from a transformer.

The calibrated voltage attenuator is simply a resistive divider across the input. A standard shielded probe with a ground clip is used for pickup. A blocking capacitor keeps dc from being applied to the divider, and hence to the FET preamplifier gate.

The entire voltage divider, with its switches, lead wires, and input capacitor, should be shielded from stray pickup. Without shielding, it is subject to hum, rf, and other stray pickup which shows on the meter and is audible in the monitor. The input impedance is approximately one megohm. Many of the pickup problems can be solved by shunting the whole string with a one-meg (or lower value) resistor, thereby lowering the input impedance without changing the 10-dB interval between attenuator taps. (If this is done, it is necessary to recalculate the value of R7 to give 50 dB attenuation with the new divider resistance.) You might provide a switch to do this, so that you can retain the one-meg input impedance for use when you're working with very high impedance sources.

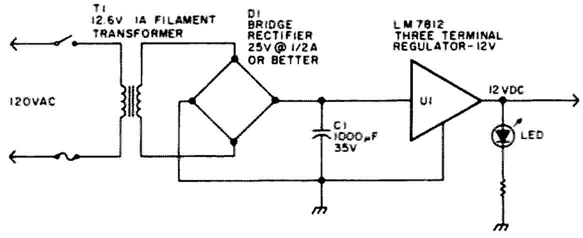

Fig. 2. Power supply for the VUM.

Resistance values are chosen such that each switch position gives 10 dB less signal than the one above it, for a total of 50 dB attenuation below the input signal. When the "high level" switch is flipped, an additional, fixed 50-dB attenuator is thrown into the circuit and the switch then reads in 10-dB steps from 50 to 100 dB below the input—and that's a *lot* of attenuation!

How do you determine the resistance values? That caused me a lot of floundering around with my trusty TI-55 calculator and a ream of paper smeared with several grams of graphite scribblings, but it finally came clear. As I said, the secret is that a dB is a *ratio* between two values, and you have to start with one known value and go from there.

You arbitrarily can assume a total value for the divider of one megohm, and calculate each step as a portion of that, or you can arbitrarily assume some value for R1 and calculate each step from there. I chose the latter because it enabled me to use a 10-dB ratio in all calculations, thus greatly simplifying the calculator work.

Now, let's go back to the basic formula stated earlier and solve it for 10 dB: 10 dB = 20 log V2/V1. Therefore, antilog V2/V1 = 10/20 = 0.5. The antilog of 0.5, obtainable from the calculator or a log table, is 3.1622777. So: V2/V1 = 3.16 and V2 = 3.16 V1.

In any purely resistive network, voltage divides in exact direct ratio to the resistance, so we can substitute R1 and R2 for V1 and V2 and restate the formula R2 = 3.16 R1.

Now, let's assume a value of 1000 Ohms for R1 (see Fig. 1). R2 is then 3.1622777 × 1000 = 3162 Ohms.

That gives us the values of two resistors in the string. Now let's get the value of R3. We want a value which will give us 10 dB less voltage across R1 + R2 than is applied across R1 + R2 + R3. So, R1 for this calculation is actually the sum of R1 and R2, or 4162 Ohms. Therefore: R3 = 3.16 (R1 + R2) = 3.16 × 4162 = 13,146 Ohms.

To get the value of R4, use the same method, making "R1" equal the sum of R1 + R2 + R3. And so on, until you have the value of all six resistors in the string.

Now, it happens that 1000 Ohms is a standard resistance value. That's why I chose it. Three thousand Ohms, however, is not a standard value, and 3162 certainly is not! However, 2700 and 470 are standard values, and they add up to 3170 Ohms, which is only 0.2 percent off the calculated value! Certainly close enough for amateur work.

13,146 isn't standard, but 13k is, and it is only about 1.0 percent off. If you want to be *really* finicky, you could use 13k and 150-Ohms in series, but, unless you're using very expensive 1% tolerance resistors, the difference is academic. Five percent is certainly close enough and ten percent probably will do nicely.

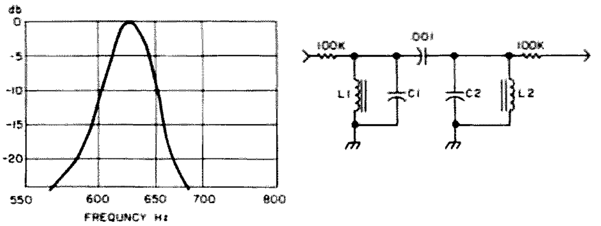

Fig. 3. Frequency response of two-toroid CW filter determined with the aid of the VUM. L1, L2—88-mH toroids; C1, C2—0.68 μF. Bandwidth: 25 Hz at −3 dB; 40 Hz at −5 dB; 55 Hz at −10 dB; 60 Hz at −15 dB.

Calculated values of the other resistors can be approximated in the same way, using standard values in series, parallel, or series-parallel. In most cases, quarter-Watt composition resistors will do fine. However, compostion tends to change value slowly over a period of years, especially when subjected to heat and/or high-voltage stresses. You could avoid this with metal film resistors, at much expense, but one-Watt or even two-Watt composition resistors will hold their values for many years before they change enough to affect the accuracy of your readings.

The resistors are easily mounted on a small piece of perfboard with wires running to the six-position rotary switch, but keep the leads fairly short, keep them away from output leads going to the speaker or meter, and keep them away from power-supply leads. If possible, enclose the whole resistor bank and switch in a shielded compartment, though this may not be necessary.

The FET amplifier is not needed to provide gain, though it provides about 10 dB. It is there to offer a very high impedance to the voltage divider. The input impedance of the LM386s, in parallel, is about 25k and if this impedance paralleled the attenuator, it would seriously affect the accuracy of the steps, especially at the small attenuation settings. Any inexpensive audio-type N-channel FET will work nicely. The FET drives the two pots which provide separate level controls for the amplifiers.

The meter amplifier is coupled to the 4-Ohm winding of a small audio transformer with a 500- or 600-Ohm secondary, such as those used to couple speakers to music distribution lines. The purpose of the transformer is to step up the low-voltage output of the amplifier to the higher voltage which the meter needs. The meter is designed to work across a nominal 600-Ohm load.

Except for lead dress and shielding of the input circuits, nothing is critical about construction. The audio amps, including the FET circuit, can be built on a single universal circuit board such as the "experimenter printed circuit board" sold by Radio Shack (catalog number 276-170) or any other "universal" board with 0.1-inch perforation centers. It can be built on perfboard without foil using wire-wrap or point-to-point wiring.

A regulated power supply (Fig. 2) using a three-terminal 12-volt IC chip is used because the regulator provides a high degree of hum filtration. Voltages are not critical at all, but don't exceed 15 volts—the 386s cannot take more than that. Nine-volt batteries should work fine.

After checking for wiring errors, plug in the ICs and check for output. You should find none until you provide an input signal. If hum appears on the meter and/or in the speaker, especially at the 0-dB attenuation setting, short out the probe terminal and see if it disappears. If it does, your problem is hum pickup in the attenuator board.

Occasionally IC amplifiers will oscillate. This would show up as squeals, hisses, crackles, and distortion in the speaker and as a reading on the meter, even with the probe input shorted or switched to high attenuation. This usually can be cured with an RC filter (0.05 μF and 10 Ohms in series) from the IC output to ground. Sometimes a 0.005-μF capacitor across the input terminals at the IC will be necessary. The FET can be eliminated as a suspect oscillator by grounding its gate or by removing its drain voltage.

After checking out and debugging, hook a source to the input of the VUM. The best source is an audio oscillator, but for this test, any steady tone will do.

You should hear it in the speaker and should be able to adjust its loudness with the "volume" pot.

The tone also should register on the meter. If it pegs the meter, rotate the attenuator switch until the meter drops back on scale. If little or no meter reading occurs, set the "calibrate" (Cal) pot at about half rotation or a little more, and then, if necessary, rotate the attenuator switch toward the 0-dB position.

Checking Calibration

Adjust the output level of the oscillator until you can set the attenuator at 0 dB and get the meter down to 0 VU (about two-thirds scale) with the Cal pot. Now flip the attenuator to −10. The meter should drop to −10. Reset Cal and, if necessary, the oscillator output, to get 0 VU again, and switch the attenuator to −20. The meter should again drop to −10.

Check all six steps in the attenuator in this way. You may find it necessary to adjust a resistor value here or there to get exact 10-dB steps. (Remember that R6 controls the first step from 0 dB to −10 dB. R5 controls the next step and so on.)

The full range of the Cal pot will give you about 25 or 30 dB of adjustment.

Using the VUM

Now you're ready to put the VUM to practical use. You have an audio filter for use in CW reception. How sharp is it? Put it on the bench and arrange to drive its input with the audio oscillator instead of the receiver. Be sure that the input and output of the filter see the same impedances they see when it is in the receiver, then put the VUM across the output of the filter. Let's assume that the filter was designed to peak at 700 Hz.

Adjust the frequency of the oscillator until it hits the filter peak, giving maximum reading on the VUM. Select an attenuation on the switch which will let you set the meter on 0 VU with the Cal pot.

Note that your oscillator frequency is 690 Hz when the filter output is peaked—pretty close, if you designed it for 700 Hz. Now, keeping the output level of the oscillator the same, switch the frequency to 700 Hz. You'll note a slight drop in the VUM reading. Note that at 690 Hz, the VUM read 0 VU and at 700 it read, say, −0.5 dB.

Change frequency again, to 710 Hz, and note that the meter reading drops to −1 dB (or VU). Keep going up frequency one step at a time until your meter readings drop below −20 dB. Then go down frequency from 690 Hz a step at a time, noting the meter and frequency readings each time.

When you finish, plot your results on a piece of semi-log graph paper, using the logarithmic scale for frequency and the linear scale for your dB readings. The results will be similar to those in Fig. 3, which represents an actual two-toroid CW filter I've used for years. The response curve was plotted with the aid of the VUM.

In a similar manner, you can determine the frequency response of a stereo amplifier, beginning in the middle of the audio range, say at 1000 Hz, to establish a 0 VU reference point. You will note that the meter readings begin to drop off as the frequency reaches some low value, perhaps below 100 Hz, depending on the quality of the amplifier. A similar drop-off occurs at the high end of the audio range, say, above 15 kHz.

The frequency response curve of the VUM itself is shown in Fig. 4 and this must be taken into account when testing another amplifier. The low frequency drop-off is caused, most likely, by the core losses in the small output transformer used to couple the amplifier to the meter. Up to a certain point, increasing the value of the output coupling capacitor will extend the low frequency response. You should use at least a 3000-μF coupling capacitor.

An op amp, such as an LM741 or TL081 driving the meter directly and omitting the output transformer, probably would improve the extreme low end response of the VUM. Since I have seldom, if ever, been called on to make accurate measurements at these frequencies, I have not explored that improvement. The high frequency response is virtually flat at least to 40 kHz.

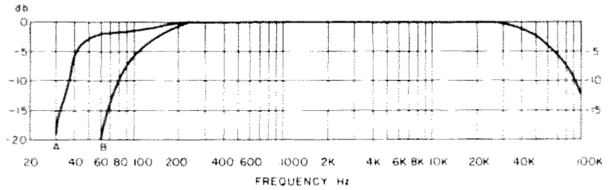

Fig. 4. Frequency response of the VUM. ±1 dB, 100 Hz to 40 kHz; ±3 dB, 40 Hz to 65 kHz. A—response with 200-μF output coupling capacitor to meter. B—1200 μF.

Now, suppose you have a solid-state audio amp which gives only low, distorted output. Apply a tone, such as 1000 Hz, to the input, at a level which the amplifier is designed to handle. Apply the probe of the VUM to the input, adjust the attenuator, and set Cal for 0 dB on the meter.

Now move the probe to the output of the first stage in the amp and note that you must switch in two more steps of attenuation—20 dB—and the meter then reads +2. (Don't touch Cal.)

The readings translate to mean that the first stage is providing 22 dB of amplification—a very healthy performance.

Reset Cal to give 0 on the meter and move the probe to the output of the second amplifier stage. This time, it isn't necessary to switch in any more attenuation. The meter reads −5 dB. That "amplifier" stage is offering a 5-dB loss! It is obviously sick and needs TLC.

The uses of the VUM are numerous and you probably can think of other ways to use it to compare the levels of any two audio signals. Often, that tells the whole story. ■

Analog Isn't Dead

—don't be LED astray by the digital revolution

Sometimes it seems that everything is going digital. At first it was a novelty to have a digital clock—you know, the kind with the metal plates that would flip down a new number every minute. With the emergence of the cheap LED seven-segment device, the movement to digitalize everything accelerated. First it was digital watches and clocks, then calculators; now it's used on thermometers, bathroom scales, radio dials, gas pumps, and almost everything on some luxury cars. Even a farmer friend of mine brags that the speedometer and tachometer on his new tractor is digital. Digital is becoming synonymous with modern, while analog is considered outdated. Is the analog device a twentieth-century dinosaur doomed to extinction in this era of rapidly advancing technology? The answer is a definite "no!" Old Charlie Darwin would agree that as long as a species is successful within its niche, it will survive. As it has evolved because of technology, the digital species has displaced the analog species from certain niches in which the analog species was only marginally fit, yet digitals are unable to compete with analogs in other areas.

Analog and digital devices each have distinct advantages and disadvantages. By understanding the merits of each system, the designer/user can intelligently select the better device. As a rule, a merit of one system is a shortcoming in the other system.

Precision

The digital device wins hands-down in the precision department. Precision is limited only by the number of digits you can afford or can read without confusion. But don't get confused between precision and accuracy. Accuracy is the measure of how close you are to the real value, while precision is the measure of your confidence in the measured value. If your new Rockcruncher 2000 all-digital transceiver says that you're transmitting on 21,447.605 kHz (a very precise measurement), but you are actually transmitting on 21,452 kHz (a very accurate measurement), then you are still likely to get a pink slip from the FCC. Moral: An ounce of accuracy is worth a pound of precision. However, if you have a high degree of accuracy but low precision, you won't be able to know just how accurate you are. You just won't collect as many pink slips.

Quick quiz: Which digital frequency meter is better (greater accuracy and precision) for measuring a signal at 420.0000000 MHz: a 6-digit meter with 1 ppm accuracy or a 10-digit meter with 4 ppm accuracy? Answer: Of course you knew all along that it was the 6-place meter, because:

6-place counter:
1/1,000,000 × 420.0000000 + 420.0000000 = 420.000 (remember, only 6 digits).

10-place counter:
4/1,000,000 × 420.0000000 + 420.0000000 = 420.0016800.

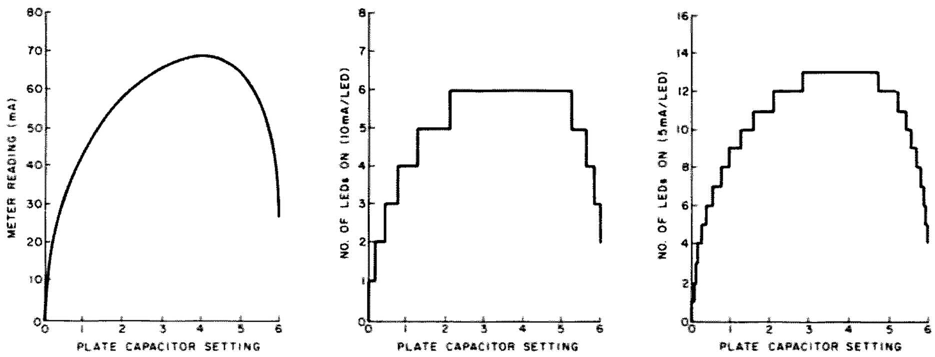
Wow! The 10-place counter is really impressive with all those numbers. It's too bad that the accuracy extends only to five significant figures. The 6-place counter is not as flashy, but it provides accuracy and precision to six significant figures.

The slide rule was displaced by the digital calculator simply because the slide rule was unable to compete with the superior accuracy and precision of the digital calculator.

Rate Measurement

Imagine that you have decided to update your old Rockcruncher 1000 (1967 model with analog frequency dial and old-fashioned D'Arsonval swinging-needle meter movement). Being short of funds, you select a $19.95 3½-digit LED meter kit to replace the old analog movement. After three weekends, one trip to the hospital emergency room, and the kind assistance from a friend who just happens to have an MSEE degree, you get the thing installed. To celebrate the occasion, you turn on the rig to 40 meters for a little QSO to brag about how you dragged your old Rockcruncher 1000 kicking and screaming out of the 1960s and into the 1980s.

As you tune in the first station, you get the first hint that all is not well with your new, state-of-the-art, digital



(a) (b) (c)

Fig. 1.

meter. It is impressive to see all those LEDs flashing, but it would be better if they were readable instead of blurred. Well, that's the price of progress.

Then you start to tune up the rig. The old peak-and-dip ritual is suddenly a wild and crazy experience. Unless you tune very slowly, the meter displays a string of eights. Not only that, but finding the peaks and dips is almost impossible. Unfortunately, the final tubes hate non-resonance so much that by the time you are almost tuned up, they collapse in a molten puddle.

Exaggerated? Well, maybe, but the point is that digital displays are not suitable for measuring rapidly changing values. The digital display blurs, while the analog display provides a usable rate-of-change display by observation of the angular velocity (sweep speed) of the indicator's pointer. An example would be to compare the analog and digital display of an aircraft's altitude. During an aircraft's descent, the analog altimeter's pointer "unwinds" at a velocity proportional to the slope of the descent. The display remains readable at all times. The digital display will blur in the units position during the slightest descent, and as descent rate increases, the tens, hundreds, and eventually thousands positions will blur. While the analog altimeter provides continuous rate information over a wide range (slow "unwinding" through fast "unwinding"), the digital altimeter displays the descent rate in a limited number of discrete steps. For example: units blurred—slight descent; tens blurred—moderate descent; hundreds blurred—steep descent; thousands blurred—dive; ten-thousands blurred—don't even think about it.

Why do race cars still use old-fashioned analog tachometers instead of the spiffy new digital tachometers that Warshawsky and Co. sells? It comes down to economics. An over-revved engine with pieces littering the track simply cannot win a race. If a digital tach blurs on acceleration, the driver will be more likely to overrev the engine (an expensive mistake). The subject of race car instruments leads into the next criterion for selection of the appropriate analog or digital device.

When I first saw the instrument panel on a race car, I noticed that the instruments were installed askew, with some turned clockwise and others turned counterclockwise. Later I was informed that it wasn't sloppy installation, but an intentional arrangement. The driver doesn't have time to read the numbers on each gauge, so the gauges are aligned so the pointer is at 12 o'clock at the ideal (or maximum) setting. A deviation is then readily noticeable. An analog device will show where you are with respect to the range of position. An analog defines its limits (empty-full, low-high, 0-1 mA, 0-120 mph) and the device's pointer simultaneously indicates its relative position on the range of values.

Comparing the ability of analog and digital devices to measure position can be demonstrated by the story about the hot-air balloonists who became lost while drifting over the countryside. One of the balloonists sighted a farmer in a field and began releasing gas from the balloon. As the balloon passed over the farmer, the balloonists yelled, "Where are we?" The farmer replied, "'Bout a hunnerd foot up in a hot-air balloon." The information transferred was absolutely correct, yet absolutely useless since there was neither a horizontal point of reference nor a distance and direction from the point of reference. Frequently a value alone can be meaningless unless accompanied by boundary limits. When using digital devices, you often must be aware of limits which are not displayed. Since analog devices display the entire range, hazardous or undesirable regions may be flagged by using a colored band as a warning marker. This flagging is generally not available for digital displays; however, red/green bidirectional LEDs in a 7-segment configuration could be used in circuitry that would allow a color change as an undesirable region is entered.

Another kind of position utilization in analog displays is incremental measurement. A good example is the wristwatch worn by a nurse. It is never digital and always has a second hand. The reason is that nurses take frequent readings of patients' vital signs—pulse and respiration. To save time (a survival skill in nursing), the pulse and respiration are each measured for 15 seconds. The procedure is to find the pulse, start counting the pulse as the second hand passes any 5-second increment, continue counting until the second hand has traversed 90° from the starting point, and finally multiply this 15-second count by 4. The starting and stopping points are of no consequence, but rather the 90° sweep of the second hand which measures a 15-second increment. A similar incremental measurement is used in transmitter tuning. The actual plate current reading is of little value until tuning is completed. The important things are the relative peaks and dips as the circuit is brought to resonance.

Continuous vs. Stepped Readings

There is a little gadget on the market called the LED bar-graph display which looks like an analog device, yet is still digital. It has the advantage of position display and may be used marginally for rate measurement. Its weakness is the one distinct advantage usually found in digital devices—precision. Precision is limited by the discrete number of steps (LEDs) on the bar display. If 8 LEDs

are used to measure a range of 0 to 8 units, then no LED would light until one unit is reached, the second LED would light only when two units is reached, and so on. The drawback is that 1.00 and 1.99 units are displayed as being the same. Now it's obvious that trying to use this bar graph to tune a transmitter would be difficult. Fig. 1 shows a comparison of a D'Arsonval meter movement and two LED bar graphs. Fig. 1(a) shows the actual plate current (as displayed on the D'Arsonval meter). Fig. 1(b) shows an 8-LED bar graph, and Fig. 1(c) shows a 16-LED bar graph. The "peak" on the 8-LED bar covers over half of the capacitor tuning range, and the 16-LED bar-graph "peak" covers over a third of the capacitor tuning range. Neither bar graph has the sensitivity for tuning that the analog display has.

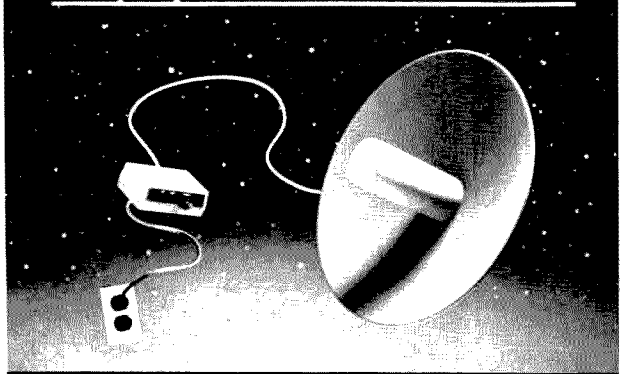
Conclusions

Use a digital device where precision is needed, but remember that high precision cannot improve accuracy. Digital devices are especially suited as frequency indicators on transceivers and frequency counters. However, if the frequency counter you are thinking about buying has 9 digits and 10 ppm accuracy, then you are wasting money on the last 4 digits. Six digits and 1 ppm accuracy is just right. Don't use an LED bar graph if precision is essential.

If position-orientation, -tracking, or -setting are important, stay with an analog device. And finally, rate measurement belongs to analog devices.

As an equipment designer/user, select the better device to meet your own needs—even if it means being old-fashioned. ■

SATURN V
STATE-OF-THE-ART



The Saturn V is a deep fringe microwave receiver for homeowners that are outside of the service area of local pay TV stations (i.e., HBO, Showtime). It is normally used within line of sight of a transmitting tower in a 50 mile range and is simply attached to your TV antenna mast. This unit is completely ready to install including all cable and mounting hardware. It is designed to be installed by the homeowner.

We accept MasterCharge & Visa.

MOR GAIN
1/2-size (75M only 66')
Multi-Band (5, 4, 3 bands) 80/75M thru 10M
Broadbanded - no traps used
Prices start at $82.50
MOR GAIN

THE MOR-GAIN HD DIPOLES are the most advanced, highest performance multi-band HF dipole antennas available. Patented design provides length one-half of conventional dipoles. 50 ohm feed on all bands, no tuner or balun required. Can be installed as inverted VEE. Thousands in use worldwide. 22 models available including two models engineered for optimum performance for the novice bands. The Mor-Gain HD dipoles N/T series are the only commercial antennas specifically designed to meet the operational requirements of the novice license. Our 1-year warranty is backed by nearly 20 years of HD dipole production experience.

Line Voltage at a Glance

—at last, a useful gadget

L. B. Cebik W4RNL
5105 Holston Hills Road
Knoxville TN 37914

A line voltage monitor can help you protect your equipment investment from problems that fuses and circuit breakers cannot cure. However, most monitors start with relatively expensive meters. To expand their scales for the 90-to-140-volt range may require additional circuitry. There must be an easier way.

The little monitor described here is inexpensive, easy to build, and provides LED indication of the line voltage in five-volt increments, which is as close as most of us need. Its accuracy is good because you can calibrate it against factory- or lab-calibrated instruments. Finally, the entire works are small enough to fit inside another piece of gear, or you can use a separate small case. Apart from the case, $10-12 should buy you new parts, although I suspect most junk boxes have everything exept the IC and the LEDs.

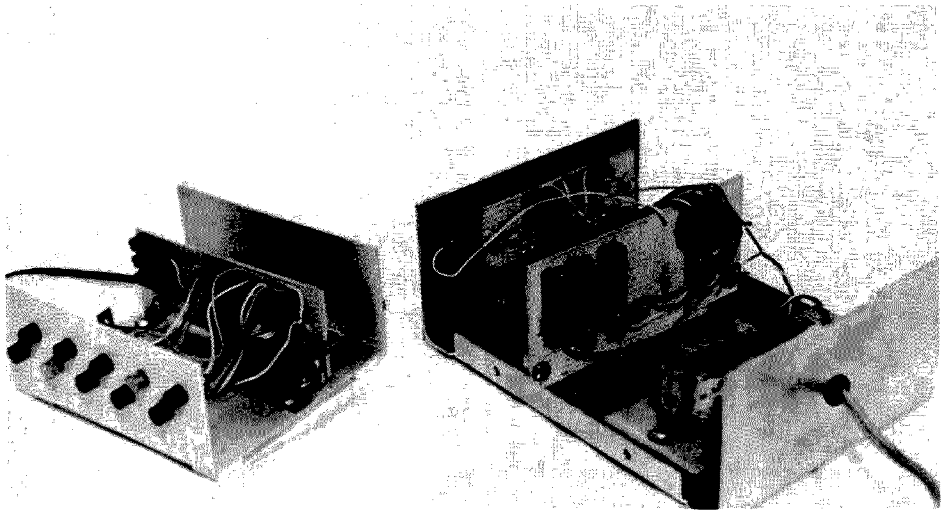
Monitoring the line voltage to the shack has always been fairly important. In recent years, the increasing incidence of brownouts and other line variations has made monitoring even more important. Occasionally voltages will rise or fall to levels which may endanger some equipment, especially motorized equipment. Less catastrophically, a line voltage monitor can help you trace unusual glitches, such as excessive power consumption, to the voltage entering the equipment. At the end of the article, we will look at some applications of the simple monitor described here.

The Circuit: An LM3914

The LM3914 dot/bar display driver is a versatile 18-pin IC available from many sources, including Radio Shack. Pins 1 and 18 through 10 provide terminations for LEDs, which can be set up to come on one at a time or to come on progressively, depending upon how pin 9 is connected. Pins 2 through 8 provide the supply, control, and signal inputs. Fig. 1 shows the basic layout of the chip.

The 3914 consists of a highly accurate voltage divider chain controlling the LED pins through complex internal circuitry. By setting the high and low limits of the divider, we can achieve a smooth linear progression of lights as the voltage moves up and down at the input terminal, pin 5. Most applications of the 3914 are geared to low voltages, such as audio voltage meters, battery checkers, and the like. However, with a little care, we also can have the 3914 track higher voltages.

To make the 3914 function as a line voltage monitor, we simply need a low dc voltage which varies with the rms value of the ac voltage at our wall plugs. A 9- to 12-volt dc power supply with a relatively constant load will do just this, if the supply is loaded neither too lightly nor heavily. Additional drops across a resistor will also track the ac. In the circuit shown in Fig. 2, tracking by these means has proven as accurate as the expanded-scale ac meters against which the unit was checked.



Interior view of these monitors shows two layout possibilities using perfboard construction.

The circuit in Fig. 2 is an adaptation of the 3914 configuration used by Weinstein and Gartman in their auto battery checker.[1] The resistor divider networks connected to pins 4, 6, and 8 set the lower and upper limits of the readout, while the resistor connected to pin 7 controls the brightness of the LEDs. Pin 5 samples the incoming voltage across another resistor

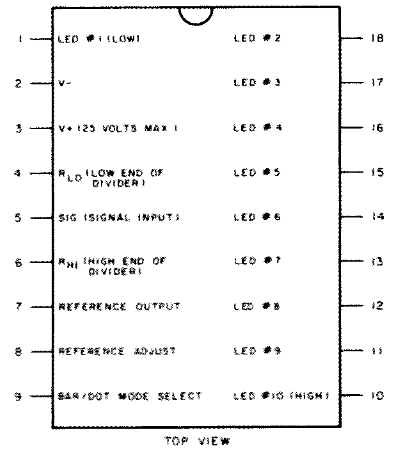


Fig. 1. Pinout of the LM3914 dot/bar display driver.

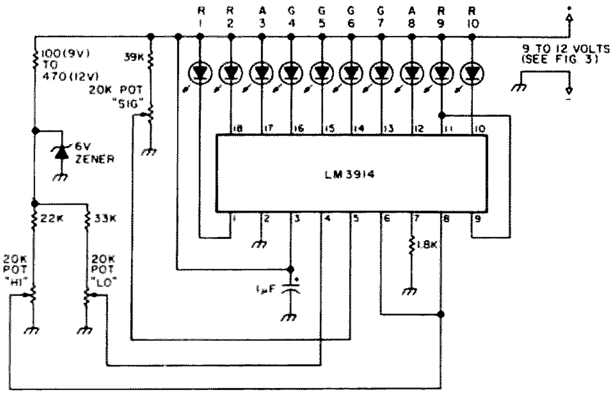

Fig. 2. The metering and LED sections of the line voltage monitor. LEDs: R = red, A = amber, G = green.

divider. Jumpering pins 9 and 11 allows the LEDs to light one at a time.

Each LED lights for a five-volt increment from 90 to 140 volts. The one exception is the last LED, at the upper limit, which remains lit when the voltage exceeds 140. The 50-volt range was chosen for several reasons. First, 50 divides neatly by 10. Second, the middle four increments cover the range from 105 to 125 volts, the recommended range for the operation of most electronic equipment. Hence, the readout has a nice symmetry. This fact also allowed me to use different colored LEDs: green for the safe range, red at the dangerous extremes, and amber in between.

The zener in the line feeding the limit-setting resistors is needed to hold the voltage constant to the limit pins. The exact value is not critical, as long as a range of 1 to 3 volts is available from the potentiometers. The pots are 10-turn miniature trimmers for ease of calibration. (Remember that what is called a 10-turn mini pot may have from 8 to 15 turns depending upon the model and manufacturer.) The input trimmer is the same sort of miniature potentiometer, set to give around 2 volts for an ac rms line voltage of 110.

The LEDs can be any type of the many available across the counter or through mail sources. The object is to create an easy-to-read display, remembering that pin 1 is the lowest, pin 18 is next, and pin 10 the highest value. The 1.8k resistor controls the brightness of the LEDs, and the value shown provides an easy-to-read level without being too obtrusive.

The remainder of the circuit is shown in Fig. 3 and consists of two different power sources for the meter. The original prototype was built with power supply components on hand, while a second version uses a 10-volt ac adapter, with the parts molded into the plug. Anything from 9 to 12 volts will work, so that the ac adapter for a dead transistor radio, tape recorder, etc., can be pressed into service with good results. The meter requires little current, so the current capability of the power supply is not a problem. However, whether you opt for a home-brew supply or an adapter, additional filtration and a load resistor (the 1k resistor in the schematic) are needed to provide a minimum load on the supply.

Construction and Components

The meter itself, as shown in Fig. 2, will fit on a 2″ × 3½″ piece of perfboard, assuming the LEDs are panel-mounted elsewhere. A socket for the IC simplifies wiring. Since only a few of the IC pins have more than one connection, wiring is so easy that no printed-circuit techniques have been used, although an enterprising builder might wish to create a board for himself.

Again, with the exception of the LEDs, there are so few external components that layout is no problem. The only caution is to mount the trimmer pots so that they are accessible for calibration. Since they are of the same value, it will pay to label them as HI, LO, and SIG. There is nothing more exasperating than to have the unit in the final tweaking stages of calibration, only to move the screwdriver adjustment of the wrong pot and have to start over.

Different types of LEDs and panel arrangements can be used with equal success. Rectangular bar-graph LEDs from Radio Shack have been used in one model. They are mounted on a piece of perfboard, with leads running to terminal pins on the board. A smaller unit uses jumbo LEDs in plastic mounting lenses. The zigzag line of ten LEDs across the face of the unit makes identification of the five-volt increment very easy, and once panel markings are added, readout is even simpler.

Fig. 4 shows a sketch of the front panel with the colors of LEDs identified. The arrangement from red through amber to green and back again is not only symmetrical, but also reflects the levels of potential trouble from line voltages that wander too far from the norm. In purchasing LEDs, especially green jumbos, be sure to buy more than you need and match them for brightness. The reds and ambers seem to be most consistent, but surplus greens appear to vary quite a bit.

The importance of using LEDs of approximately the same brightness stems from the fact that as the voltage nears a transition from one increment to another, two LEDs may be lit simultaneously. If the LEDs are well-matched, the relative brightness of the two will tell you which side of the dividing line the voltage is on at a given moment. Mismatched LEDs can misinform you. This trouble was not encountered with bar-graph LEDs. The degree of overlapping of LEDs seems to vary from IC to IC, but in no case has it proven to be such a problem as to produce false impressions of the line voltage.

If you use a home-brew power source, you can

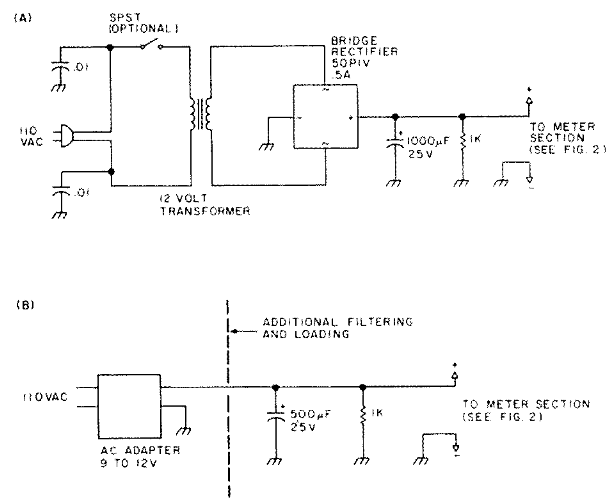

Fig. 3. Power and signal source for the line voltage monitor. (a) Home-brew power source. (b) Ac adapter module power source.

build it on a separate board or use one board for the supply and meter sections. With an ac adapter, the additional components can go on the meter board with the IC and pots. The only precaution with the power source is to use it for no other purpose. The varying load created by a secondary use will alter the voltage to the signal input, destroying the utility of the meter.

The entire assembly is compact and will fit cases as small as 2"×2"×4" (with an ac adapter supply). The components also can be mounted within another piece of equipment as long as there is room somewhere for the LED display. If your shack has a master ac control panel, a small corner will be enough for the LED array.

Calibrating the Meter

Many of us have grown accustomed to using fixed components or having equipment factory-calibrated. In the process, we may lose sight of the fact that building an adjustable circuit can lead to a far more accurate instrument. Hence, potentiometers have been used rather than fixed voltage dividers.

The line voltage monitor described here can be calibrated at two levels of accuracy: close and right on. Close calibration requires only a fairly accurate VTVM and a little arithmetic. To get the meter right on requires a factory-calibrated meter (for ac and dc voltages) and a simple test circuit. The close calibration technique is also a good preliminary step for later, more precise calibration.

Let's begin with a little math. Suppose we let a signal input voltage of 2 volts dc to pin 5 of the LM3914 equal 110 volts ac. The voltage division factor is 55. (We could, of course, use other ratios, within limits.) This factor will apply throughout the meter range. Dividing 90 volts ac by 55 gives us a value of 1.64 volts dc as the lower limit control. Measure the voltage at pin 4 and set the LO pot for this voltage. Similarly, 140 volts ac divided by 55 gives 2.55 volts dc as the value we want at pin 6; adjust the HI pot for this value. The HI and LO pots may interact a bit for this degree of accuracy, so tweak both several times to set the final values. Now adjust the SIG pot until the correct LED lights for the actual value of ac voltage.

Use caution here. Most kit VTVMs were aligned for 110 volts ac from the existing line voltage. Thus, they will be no more accurate on ac than the original adjustment. If you can borrow a well-calibrated instrument or visit a lab bench for a few minutes, you can set the line monitor on target quickly. Do not expect to read exactly 2 volts for 110 volts ac, because there will be a slight offset, but the degree of inaccuracy caused by this is under 1 percent. With a little tweaking back and forth of the signal input pot, you will be able to set the voltage very accurately by watching for the overlap effect on the LEDs.

The monitor is very usable calibrated this way, but if you wish to be more accurate, try the circuit in Fig. 5. This circuit lets you vary the ac voltage to the monitor across the full range of the instrument. Use care, because the voltage can be lethal, and there is a tendency to grow a bit careless after handling the low voltages we use on ICs. The 5k pot should be 4 Watts or more and well insulated from your hands.

As the drawing shows, we will monitor the line voltage as we calibrate the meter. If we wish, we also can monitor the voltage to the control and signal pins, but this is not strictly necessary. If we have performed an initial calibration as described above with some care, we should be close enough to make the precision calibration easy.

First, recheck that the correct LED lights with a voltage in the 110-to-120 range. Now we will run the ac voltage up and down, checking the voltage at which the LEDs change from one to the next. (For these tests we will ignore the absolute limits, since the transitions are more accurate.) If the voltage transitions are not at the five-volt marks and they are consistently off by a constant amount in the same direction (for example, a volt too high or a volt and a half too low), then adjust the SIG pot to bring the transitions on line. If the amount of error at transition toward the low end of the scale is not constant after bringing the SIG pot as close as possible to the right point, then adjust the LO pot until the changes, especially the 95-volt transition, are correct. Do the same for the upper end of the range.

Remember that the two pots may interact just a bit, so recheck each end of the line. Be sure to make all adjustments slowly, and verify that you are moving in the correct direction before making a sizable change. Large hasty changes can throw everything off. But if everything does go askew, you can set it back in the ball park with a repeat of the first alignment procedure.

Now recheck the alignment, and you should be right on. At most, you may have to adjust the SIG pot a hair more. Although the resistor divider circuits show combinations of fixed and variable resistors, they could be replaced by 50k pots. However, there would be a loss of fine calibration control, so the cost of the three fixed resistors is well justified.

After using the monitor for several weeks, recheck the calibration. Components do change value during their lives, but most of the change (if not catastrophic) is either very early or very late in their lifetimes. Hence, after "burning in" the monitor for a few weeks, a check of the calibration should produce a stable monitor that needs to be tested only during your regular station maintenance checks.

What the Monitor May Tell You

The line voltage monitor described here is designed to be accurate, but not to yield precise voltage measurements. Within close limits, it will indicate the five-volt range of the current ac line voltage feeding your equipment. For many purposes, these readings will be sufficient. Closer readout of the voltage requires either a meter or a redesign of the present circuit. By adjusting the upper and lower limits, a smaller voltage range can be spread across the same ten LEDs. For example, within the general parameters of the two-step calibration procedure described earlier, setting the LO-HI range between 2.09 and 2.27 volts would permit you to read the ten volts between 115 and 125. If such precision is desired, a second set of resistor dividers might be switched in and out of the circuit (in place of the 50-volt dividers) with a DPDT switch.

Since the primary function of a line voltage monitor in the shack is to warn of possibly dangerous conditions, such precision is rarely required. Most of the monitor's utility is provided by the wider limits. This is especially true in this day and age of brownouts, when power companies—with or without warning—may lower the line voltage to 100 volts or less. Likewise, in some regions with a heavy industrial daytime load, early evening voltages have been reported occasionally to reach 135 volts.

Most household equipment, including ham gear, falls into four main categories: motors, lighting, heating, and electronic devices. Variations in line voltage can affect all four types of equipment, some more radically than others. Motorized equipment such as furnace fans, refrigerators, air conditioners, vacuum cleaners, stove fans, and the like all operate less efficiently as the voltage is reduced. Some types of motors can be damaged if the voltage drops too low and the motor is loaded heavily. In general, if the voltage either drops below 105 or rises above 125, it is best to shut down motors which must work hard. This includes air conditioners, refrigerators, power tools, and similar equipment. Lighter duty motors, such as fans, may be run to wider voltage limits, but do not be surprised should one fail. If any part of the motor has a weak spot, radical voltage excursions are one way of discovering it. These cautions do not mean that every drop or rise in voltage will mean catastrophe; rather, they are suggestions for preventing a possibly sizable replacement cost.

Lighting devices are generally of two sorts: incandescent and fluorescent. Light bulbs will react to line voltage variations by producing more or less light and heat. The power drawn by the bulb will vary approximately as the square of the voltage changes, since the current will also rise and fall with the voltage. The relationship is not exact, since filaments change their resistance with heat. While reduced voltage is an annoyance due to the reduced light output of bulbs, excess voltage is a bulb killer. A 10% voltage rise means approximately a 20% power increase, with an accompanying increase in heat. Using the national average ac line voltage of 117 as a standard, as little as 129 volts will produce this effect. Fluorescent fixtures are less evident in their reaction to line voltage variations, but harder starting may not always mean a bad condenser. A quick check with the line voltage monitor is in order first.

Electrical heating devices, such as stove and oven elements, are much like incandescent bulbs. Their heat output will vary as the line voltage varies, and so will the mechanical wear of the element. These are usually hardy devices, and often the adjacent wiring has a shorter lifetime than the element. Nonetheless, expect slower cooking during brownouts.

Electronic devices react to line voltage variations in many ways. Simple devices, such as tabletop radios and stereo equipment, usually show no effects from moderate drops or rises in line voltage. More complex equipment, such as television sets, may show some effects, especially with age. If accumulated dirt and other factors have lowered the high voltage to where it just holds the picture at full size, a brownout can show itself as picture shrinkage. Other effects are usually minor.

Critical equipment, such as computer terminals, should have heavy, very well regulated supplies, and the voltage feeding the regulator should not be marginal. If these conditions are met, then there are usually few problems. However, if the supply voltage to the regulator is marginal, a severe drop in line voltage may yield a temporarily unregulated supply, with consequent problems in TTL chips, memory, and other parts of the system.

Amateur transmitters and amplifiers will show the effects of line voltage variations in power output readings. In a transceiver or an average transmitter, plate voltage is usually not metered. Suppose your power output meter shows a 10% drop from the previous day's reading. One suspicion that naturally arises is that the final tubes might be going soft. However, a drop in line voltage can produce the same effect. A 10% drop in line voltage may reduce the plate voltage by 60 to 75 volts, depending upon transmitter design. Control positions also may change under these conditions, since the tube now exhibits a different plate resistance.

Rising line voltage also can yield misleading symptoms. Many of us have grown used to tuning up a transmitter to maximum power output, as read from an rf wattmeter or relative power indicator. A 10% rise in plate voltage may give us a temporary boost in power output, a condition which may make us proud for a moment of the equipment

manufacturer's ingenuity. However, if the line voltage is in fact high, then the best bet is to reduce power slightly in exchange for longer tube life. The miniscule difference in power at a receiving station cannot be noticed, but the cost of replacement finals is almost always noticeable.

Amplifiers capable of the maximum legal power for amateurs must have a means of measuring both voltage and current so that we can hold them within limits. Since most amplifiers are capable of loading to greater than 1000 Watts dc or 2000 Watts PEP input, we cannot simply choose a standard level of plate current and assume that we are within the legal power limit. A 10% rise in line voltage can produce a corresponding rise in plate voltage. Reducing plate current is then the only way to hold the power within limits.

These sample potential problems and conditions make a strong case for monitoring line voltage. Some of us are lucky enough to live in areas which never—or hardly ever—have brownouts. High line voltages are even more rare. However, the small price of a monitor will be more than offset if we detect a condition early enough to save the cost of a service call or replacement parts. For this degree of safety and preventive medicine, we need an accurate monitor, although we do not always need to know the exact number of volts. The LED line monitor described here can fulfill the need, while providing an interesting weekend of building and calibrating. ■

NOT JUST ANOTHER REGULATED POWER SUPPLY!

The FASTRAK® model 2001 voltage regulator module is ideal for making reliable power supplies in a jiffy. Use it to power your mobile rig, other FASTRAK® series modules or as a general purpose bench supply.

- Component selection sets output voltage (3.3 to 400 V dc) and current capability (5 mA to 100 A). Over voltage protection and remote shutdown included. Uses no ic's.
- One evening assembly using 2 × 3.6 inch pc board and comprehensive instructions supplied.
- Price: $10.80

Price includes: glass-epoxy, etched, plated, drilled pc board; instruction manual; postage in U.S.A. (Ohio residents add 5% sales tax).

Send $1.00 for illustrated FASTRAK® product catalog and refund coupon.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

FLAGSTAFF AZ
JUL 30-AUG 1

The Amateur Radio Council of Arizona will hold its 32nd annual hamfest from July 30 through August 1, 1982, at the Fort Tuthill Fairgrounds, just a few miles south of I-40, Flagstaff AZ. There will be thousands of dollars in prizes, improved XYL activities, a swapfest, a transmitter hunt, speakers, forums, awards, exhibits, and entertainment on Friday and Saturday nights. Overnight camping facilities will be available. Talk-in on 147.870/148.270. For further information, contact Wm. Oliver Grieve W7WGW, 4301 N. 31st Avenue, Phoenix AZ 85017, or call (802)-246-0200.

KINGSFORD MI
JUL 31-AUG 1

The Mich-A-Con ARC will hold the 34th annual UP Hamfest on Saturday, July 31, and Sunday, August 1, 1982, at the Dickinson County Armory on M-95, Kingsford MI. Tickets are $2.50 at the door (no advance sales) and registration will begin at 9:00 am on both days. There will be prizes, family activities, and a Saturday night banquet. Advance banquet reservations are needed since seating is limited. Plenty of free parking will be available. Talk-in on 146.25/.85 and .3922. For further information, write UPHAMFEST-82, 105 East Breitung Avenue, Kingsford MI 49801.

ANGOLA IN
AUG 1

The Steuben County Radio Amateurs will hold the 24th annual FM Picnic and Hamfest on Sunday, August 1, 1982, at Crooked Lake, Angola IN. Admission is $2.50. There will be prizes, picnic-style BBQ chicken, inside tables for exhibitors and vendors, and overnight camping. (A fee will be charged by county park.) Talk-in on 146.52 and 147.81/.21.

PITTSBURGH PA
AUG 1

The 45th annual South Hills Brass Pounders and Modulators Hamfest will be held on August 1, 1982, from 10:00 am to 4:00 pm, at South Campus, Community College of Allegheny County, Pittsburgh PA. Admission is $2.00 or 3 for $5.00. There will be computer, OSCAR, and ATV demonstrations, as well as a flea market. Talk-in on 146.13/.73 and 146.52. For further information, contact Andrew L. Pato WA3PBD, 1433 Schauffler Drive, West Homestead PA 15120.

BELVIDERE IL
AUG 1

The Big Thunder ARC will hold its annual hamfest on Sunday, August 1, 1982, at the Boone County Fairgrounds, Route 76, Belvidere IL. Admission is $2.00 in advance and $2.50 at the gate. A fee will be charged for 8-foot tables and there will be indoor space available in the exhibit building, as well as outdoor space in swappers' row. Sellers will be able to set up Saturday evening or at 7:00 am on Sunday. Features will include door prizes, a main prize, food, and refreshments. Camping will be available on Saturday evening (there will be a charge for electricity). Talk-in on 146.52 and 147.975/147.375. For further information or tickets, send an SASE to Jim Grimsby, 418 Beacon Drive, Belvidere IL 61008.

LEVELLAND TX
AUG 1

The Hockley County Amateur Radio Club and the Northwest Texas Emergency Net will hold their 17th annual picnic and swapfest on Sunday, August 1, 1982, beginning at 8:00 am at the city park in Levelland TX. This event is for the entire family. Bring your own picnic basket for lunch at 12:30. A two-meter FM transceiver is the grand prize. A $3.00 registration is requested but not required. There will be swapping all day, with tables provided. Talk-in on .28/.88.

GLEN MI
AUG 1

The Black River Amateur Radio Club will hold the 29th annual Southwestern Michigan VHF Picnic on Sunday, August 1, 1982, at the West Side County Park near Glen MI. (Take exit 30 from I-196 and follow the signs.) There will be swimming, a playground, a small flea market, and door prizes. There is no food available at the park, so bring your own picnic basket. Registration is $1.00. For additional information, contact Ed Alderman KI8Z, RR #2, Box 44, Lawrence MI 49064.

POMONA CA
AUG 7

The Tri-County Amateur Radio Association will hold its annual hamfest/picnic on Saturday, August 7, 1982, from 7:00 am to 1:00 pm, at the Los Angeles County Fairgrounds, Pomona CA. All buyers, sellers, and computer buffs are welcome. There will be prizes, exhibits, and refreshments. Talk-in on 146.025/.625. For more information, write to TCARA Hamfest Chairman W6ELZ, PO Box 142, Pomona CA 91769.

JACKSONVILLE FL
AUG 7-8

The Greater Jacksonville Hamfest Association will hold the annual Jacksonville Hamfest and Northern Florida ARRL Convention on August 7-8, 1982, at the Orange Park Kennel Club, located near the intersection of I-295 and US 17 just south of Jacksonville. Advance registration is $3.50 and is available from Robert J. Cutting W2KGI, 1249 Cape Charles Avenue, Atlantic Beach FL 32233. Registration at the door is $4.00. The FCC will administer amateur and commercial radio operator exams on Friday, August 6th, at the hamfest site. Those wishing to take the exams should apply to the Atlanta FCC office as soon as possible. Swap tables are $12.00 per table for both days (no one-day tables) and table reservations, as well as advance registrations, are available from Andy Burton NX4G, 5101 Younis Road, Jacksonville FL 32218. A full slate of programs is scheduled, along with meetings of statewide and regional nets and organizations, plus competitions including a rabbit hunt and pileup contest. The headquarters hotel is the Best Western First National Inn just across from the hamfest. Special rates may be obtained by writing to Jim Canfield KD4CG, 996 Dostie Circle, Orange Park FL 32073. Talk-in on 146.16/.76 and 146.07/.67.

MONTGOMERYVILLE PA
AUG 8

The Mid-Atlantic Amateur Radio Club announces its annual J. B. M. Hamfest to be held on Sunday, August 8, 1982, from 9:00 am to 4:00 pm, rain or shine. Tailgate setup begins at 8:00 am. Located at the Route 309 Drive-In Theater, 1/4 mile north of Route 63, Montgomeryville, PA (6 miles north of the Fort Washington Interchange of the Pennsylvania Turnpike). Admission: $2.50, with $1.00 additional for each tailgate space. Non-licensed XYLs and children admitted free. Ample parking, refreshments, raffles, door prizes, and more. Talk-in on WB3JOE/R (147.66/.06) or 146.52 simplex. For further information, write the club, PO Box 352, Villanova PA 19085.

SAUK RAPIDS MN
AUG 8

The St. Cloud Radio Club will hold its annual hamfest on Sunday, August 8, 1982, from 8:30 am to 4:00 pm, at the Sauk Rapids Municipal Park, Sauk Rapids MN. Talk-in on 146.34/.94. For more information, contact Mike Lynch, 2115-1st Street, St. Cloud MN 56301, or call (612)-251-2297.

SONOMA CA
AUG 8

The Valley of the Moon Amateur Radio Club will hold its third annual ham breakfast and swap meet on Sunday, August 8, 1982, from 9:00 am to 4:00 pm, at the Sonoma Community Center, 276 East Napa Street, Sonoma CA. Breakfast is $3.50 each for adults and $1.75 each for children under 12. Waitresses will serve breakfast to people manning swap tables. Hot dogs will be served for lunch. Swap spaces are $5.00 each and tables can be set up beginning at 8:00 am. (Since there are only 30 tables available, plan to bring your own.) Admission, including a raffle ticket, is $1.00 and tykes, YLs, and XYLs will be admitted free. Featured will be computer displays and demonstrations, an operating 10-meter FM station, a Sonoma Valley Quilters' table, an amateur television display, an open auction at 2:00 pm, and a raffle at 3:30 pm. Talk-in on 147.47 simplex and 146.13/.73. For further information, call Darrel WD6BOR at (707)-938-8086; for swap space reservations, write VOMARC, 358 Patten Street, Sonoma CA 95476, enclosing payment of $5.00.

HOUSTON TX
AUG 13-15

The Texas VHF Society 1982 Summer Meeting will be held on August 13-15, 1982, at the Nassau Bay Resort Motor Inn, Johnson Spacecraft Center, Houston TX. Preregistration is $5.00 for all three days and includes one free ticket for a pre-registration drawing. Each additional prize ticket is $1.00. Registration at the door is $6.00 and does not include a prize ticket. There will be special tours of NASA, exhibits, a flea market, a ham astronaut speaker, space shuttle communications, and VHF and ARRL seminars. Prizes include an all-mode VHF transceiver. range extending products from VoCom

25, 50 or 100 Watts Power — Whatever your present output level — from 200 mW hand-held on "battery saver" mode to 25W mobile or base — you can use that to drive a compact 12V power amp from VoCom for much more "talk-out" power (see chart). Each model has a front panel switch to let you go "barefoot" for short hauls, plus an L.E.D. indicator to show the mode you're in. Full 10 MHz bandwidth gives you virtually unchanged power across the entire 2-meter band. High efficiency design holds down generated heat, low input VSWR saves battery drain by your radio's final amp. Use the chart to see which VoCom Power Amplifier gives you the power out you'd like from the power that you now have.

Power Pocket™ Mobile Amplifier/Charger — Simply plug in your Icom IC-2A(T) and you have a 25W synthesized mobile rig — take it out again, all charged and ready, when you want hand-held operation. Accepts any IC-2A version. Delivers 25W RF output, 2½W audio with 4" speaker to overcome road noise. Charge pocket accepts all Icom battery packs, has independent charging switch, indicator. Mic preamp makes Power Pocket compatible with any mobile microphone and with Icom speaker/mic.

5/8 HT Gain Antenna boosts reception while giving your hand-held full quieting out of spots you're nearly dead in with a rubber duck; provides excellent improvement. Only 8" telescoped, 47" extended. Better than 1.5:1 VSWR. BNC connector.

Spring-loaded 1/4 wave antenna and 4" stubby duck also available. See your favorite amateur radio dealer.

CHELSEA MA
OCT 17

The 19-79 Repeater Association of Chelsea MA will hold its annual flea market on Sunday, October 17, 1982, from 11:00 am to 4:00 pm (sellers admitted at 10:00 am), at the Beachmont VFW Post, 150 Bennington Street, Revere MA. Admission is $1.00. Sellers' tables are $6.00 in advance and $8.00 at the door, if available. Talk-in on .19/.79 and .52. For table reservations, send a check to 19-79 Repeater Association, PO Box 171, Chelsea MA 02150.

NORTH HAVEN CT
NOV 7

The Southcentral Connecticut Amateur Radio Association's (SCARA's) third annual electronics flea market will be held on Sunday, November 7, 1982, indoors at the North Haven Recreation Center on Linsley Street in North Haven CT. Regular admission is $1.25; children under 12 with an adult will be admitted free. Sellers' spaces are $6.00. The best spaces will be assigned first. A limited number of free tables will be provided to the first reservations received. When those tables are gone, space will be available for selling from the floor or from your own table. Food will be available. Sellers may set up at 8:00 am, and walk-ins will be admitted from 9:00 until 3:00. For reservations, send check or money order payable to "SCARA" to Ed Goldberg WA1ZZO, 433 Ellsworth Avenue, New Haven CT 06511. Include an SASE for confirmation.

HAM HELP

I need information on an Abbott TR-4 and an Abbott TR-4B. I would also like information on Navy type CRI-43044, a unit of Model TBY-8 and Model TBY-7.

Craig Renler
7418 Lesada Dr.
Baltimore MD 21207

I need operating/maintenance manuals for the following equipment: Yaesu FT-707; Astro 150A; Hewlett-Packard Model 122AR oscilloscope; Anton Elect. Corp. TS-505 D/U VTVM; and Shallcross ZM-3/U capacitance analyzer.

I will buy originals or pay for copying.

H. Hutchison
N4GQE, HP1XHH, N4GQE/YSI
USMILGP, El Salvador
APO MI 34023

I am looking for an instruction or technical manual for an old BC 211M frequency meter as well as for a CW filter for a Galaxy GI 550A transceiver. I will pay.

Bob Currier KA5ETF
5529 Marblehead
Jackson MS 39211

I would appreciate any information on a frequency counter which could be used with the Collins 51S-1 and 51J-4 receivers. I am also looking for anyone who has modified a 51J-4 to receive FM or who may be able to supply a suitable modification.

Clano Strachan C6ANI
PO Box N4106
Nassau NP
Bahamas

I am in need of a schematic or manual for an RCA Institute scope. Tubes are 1V2, 6BL8, 6D10, 6X4WA, (2) 12AU7s, and WX5078 P1. I will pay for the information.

J. W. Hopson W4AEM
959 Overhill Drive
Alexander City AL 35010

I need the QSL cards of those who are Church of Christ hams for the 1983 Church of Christ *Callbook* I am putting together.

Ray Hawk NW4L

Confessions of a Counter Evolutionary

—the best circuit yet?

Editor's Note: The LSI Computer Systems LS7030 counter chip used in this project is available from Belco Electronics, 43 South 49th Ave., Bellwood IL 60104, for $12.75 plus shipping. Next month we'll bring you the conclusion of WA2FPT's discussion.

As many of you may have done already, I had vowed never again to be lured into reading another frequency counter article, one more of those ubiquitous "counter updates," or even another of the scores of ads splashed over the pages of ham magazines. I was certain that I had been told more than I ever wanted to know about counters.

Why have I yielded to temptation (lured by the possibility of publication) and become a part of this ever-increasing problem? I confess! The truth is, I was seduced by an LSI counter chip, the LS7030 from LSI Computer Systems, Inc. This little beauty measures a full 40 (pins, that is) and is an 8-decade, multiplexed up counter. It counts directly to 5 MHz, is CMOS and TTL-voltage compatible, and has BCD *and* 7-segment multiplexed display outputs. It also employs and enjoys leading-zero blanking and very low power consumption. A real gem!

Even with all this on a chip, what would cause anyone, much less an impatient convenience-seeker like me, to take the trouble to design a frequency counter when there are a host of appetizing kits well within the one "centi-buck" range? I'll answer this in terms of the WA2FPT 7030 Universal Counter's features:

- 10-MHz oven-controlled crystal oscillator
- Full 8-digit resolution with no least-significant-digit bobble (no ± 1 count uncertainty)
- Four selectable timebase gate times: .01, .1, 1, and 10 seconds
- Hi-Z dc to 5-MHz preamp input
- Lo-Z 5-500-MHz preamp prescaler input
- Kilohertz, megahertz readout with automatic decimal point placement
- Period measurement with 20-period average, with direct readout in μsec to 99,999,999 (equivalent to .01 Hz)
- Events mode (totalizing) with manual front-panel controls and remote rear-panel control inputs
- Separate power regulators for the master oscillator, front ends, displays, and counter
- 10-MHz TTL test output and 6 additional buffered CMOS oscillator timebase signal outputs from 10 Hz to 1 MHz
- 25-pin E1A RS-232C type monitor jack for future remote-data acquisition and control
- Push-button front-panel operation with LED indicators—no rotary switches
- 90% wire-wrapped noncritical construction

If these features are interesting, then read on to see how to build this deluxe counter for truly a fraction of the cost of a commercial equivalent.

Before we get tangled up in our wire-wrapping, here's a short review for those who don't live and breathe digital counters. If you are one of those fortunate few

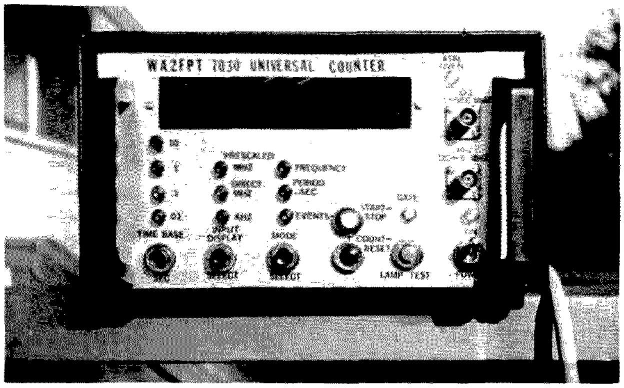

Photo A. Push-button selection is used to control the 7030 Universal Counter.

who do, then skip this short primer.

Elementary Counting

The simplest form of a counter is one that only totalizes incoming events. Fig. 2 shows three basic functional parts. The input conditioner transforms a physical event into electrical signals that are used to increment the second part. The decade counter counts from 0 to 9 and provides a carry-out to the next digit counter. The third vital element is the indicator. It decodes and converts the outputs of the decade counter to a visual presentation hopefully useful to some observer.

Fig. 3(a) shows a simple frequency *counter*. To count frequency, a "window" or "gate" must open and close for a specified time interval to give counts per second, or even "furlongs per fortnight." Any number of something counted in a unit of time is an expression of frequency. Simple enough.

Two extra items are needed, however, to make a frequency counter useful: a reset and a holding or loading device. The reset is needed to ensure that the counter begins counting from zero at the beginning of the gate time. The loading device retains the value of the last count and then updates the display with that value after the counting window has shut. This "new improved" simple frequency counter is shown in Fig. 3(b).

Period counters measure the time between events. Often period measurement is used to accurately calculate very low frequencies. This becomes necessary as the value of the frequency approaches the frequency of the counting gate. To appreciate the added resolution available for such low-frequency measurement, suppose you wanted to measure the ac line frequency. It's 60 Hz, right? Well, if you want to measure it to four significant digits, you would need a gate time of at least 100 seconds (to give a 60.00-Hz display)—a long time to wait. A simple period counter could enable us to obtain the required resolution by using our "unknown" line frequency (suitably conditioned for our digital circuitry) as the gate for a much higher *known* frequency, say 10 kHz (often readily available in timebase oscillator divider chains).

Suppose these 10-kHz pulses are then counted and displayed as before. Fig. 4 shows how the 60-Hz signal gives a count of 1668. This value is .01668 seconds, the period of the line frequency. As frequency = 1/period, and vice-versa, our 4-place readout is readily converted to frequency by using a calculator to divide 1 by 0.01668. Answer: 59.95 Hz. All we did to get this handy period counter was to interchange the "unknown" signal and the gate time. There is no waiting 100 seconds, either, as the display could normally be updated about 60 times per second.

Now that you're all enlightened, let's be counter productive and get back to the real counter.

Master Oscillator

The evolution and progression of the WA2FPT Universal Counter will be covered in pieces by looking in some detail at each of the Fig. 1 blocks.

The beating heart of any counter, the master oscillator, will be described first. The one shown in Fig. 5 is based on a 10-MHz AT high accuracy series-mode quartz crystal matched to its 85° oven. Both the crystal and oven were purchased from International Crystal Manufacturing Co., 10 North Lee, Oklahoma City OK 73102. The bucks spent here or on a similar affair will be well worth it to provide stability and accuracy for your counting machine.

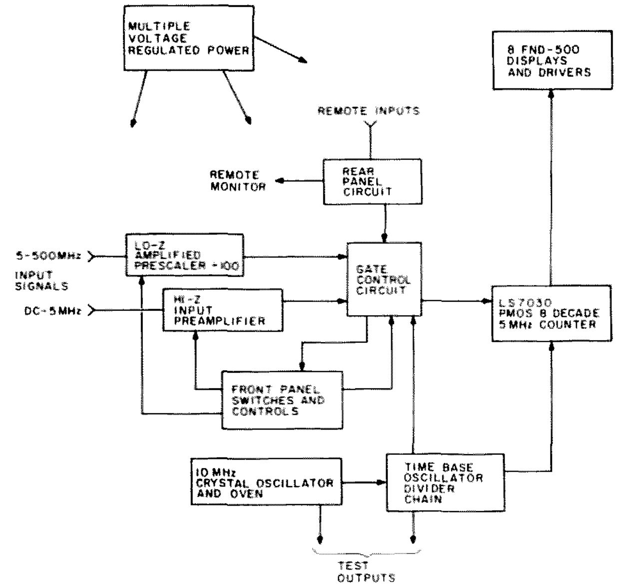

Fig. 1. Block diagram.

The oscillator itself is a 5400 TTL quad 2-input gate. A 7400 could be used, but the "Milspec" 5400 in its ceramic package was also chosen for stability (and because I had one!). The voltage regulation for the oscillator is provided by a dedicated 723 wired to give a 5-6-volt, 150-mA output. The oscillator, along with a 74LS90 decade divider, draws about 130 mA, which provides a desirably constant load. The variable capacitor serves as a coarse frequency trimmer. Except for the frequency and the 723 portion, this circuit is the same as the one WA1FUE described in his excellent counter article in the December, 1976, issue of *73 Magazine*.

I had hoped originally to build the 5400 into the oven, but soon found there wasn't enough room. Because there is a double oven, there is room for a trimmer cap as well as the crystal inside. The oven plugs into an octal socket mounted on a small aluminum minibox *containing* the 5400, the 723, and the rest of the oscillator components.

An extremely simple printed circuit board layout is shown in Fig. 6(a). This full-size board is copper-clad epoxy glass with 0.1" centered holes (Vector 169P44C1 or equivalent).

Keeping the trimmer capacitor in the oven solves a significant source of oscillator variance due to trimmer cap temperature drift. As the oven heats up to 85° C, the trimmer heats up, and, as the oven stabilizes, so does the trimmer. As you might imagine, a decent mica or ceramic trimmer (25-75 pF or so) is required here. The oven cover may have to be left off, depend-

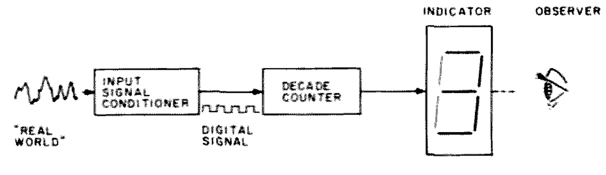

Fig. 2. Simple events counter.

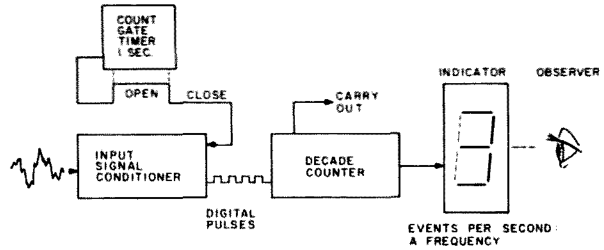

Fig. 3(a). Basic frequency counter.

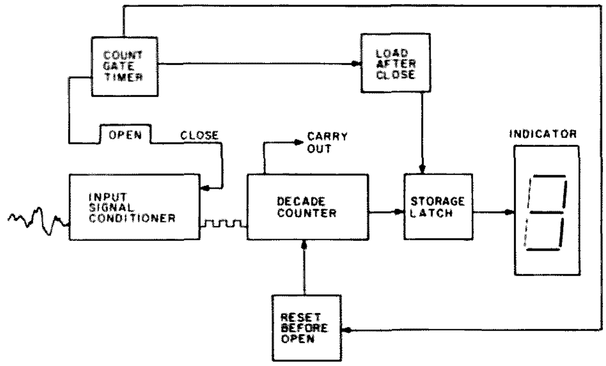

Fig. 3(b). Improved simple frequency counter.

ing on the size and/or accessibility of the capacitor's adjustment screw.

In addition to the trimmer capacitor, there is a fine frequency adjustment. The 723 has a ten-turn 500-Ohm pot to give controlled millivolt level changes in the 5-6-volt range of the 723 output. This allows minute tweaking of the output frequency. A screwdriver access hole for the trimmer pot screw was planned and cut in the minibox housing and through the counter chassis. Binding posts were provided on top of the minibox near the plug-in crystal oven for monitoring the output of the 723. This, with a rear-panel BNC 10-MHz test jack, allows convenient access to long-term oscillator drift and aging data versus voltage, if there should be a need for such logging. The 74LS90 is wired to produce a symmetrical 1-MHz square wave, and miniature coax, RG-174 or its equal, routes this signal to pin 22 of a 44-pin edge connector on the main counter board.

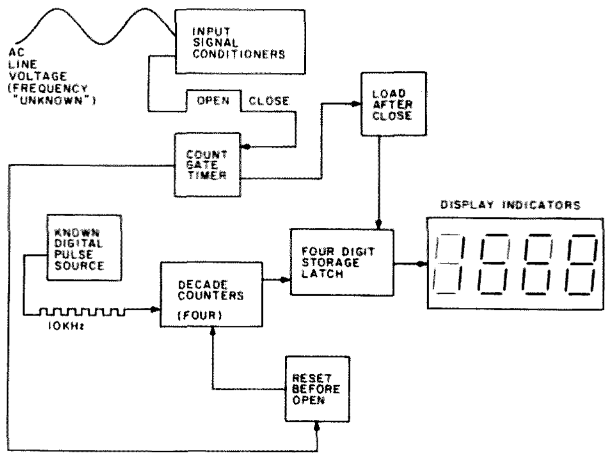

Fig. 4. Period counter example.

Timebase Oscillator Dividers

The timebase oscillator dividers (TBOD) are mounted on wire-wrapped sockets on the main board of the counter—a 4.5" × 6" Vector 3662. The wiring for the TBOD is shown in Fig. 7. ICs 3, 8, 9, and 10 are 74C90s, while ICs 2, 5, and 6 are 4029 types.

The 74C90 devices are wired as decade dividers, with the output of the ÷5 portion, pin 11, fed into the input of the ÷2 section at pin 14. The 4029 is a dual-mode (decade or binary) up-down (user-selectable) counter in a 16-pin package. In this application it is wired as a decade up counter. There is no reason why 74C90s could not be used exclusively as they are cheaper to buy and use cheaper sockets. I used both chips because I had a few of each on hand.

The TBOD, as is customary in electronic counters, provides a number of important signals that are distributed throughout the machine. The signal frequency and its destination, together with a brief description, comprise the list of pulses picked off the IC chain (see Table 1). As long as the master oscillator runs, these signals are present.

Display

The eight seven-segment common-cathode displays in this counter are FND 500 .5" right-hand decimal-point devices. They can be purchased for under a dollar apiece from many sources and are entirely adequate.

The displays are multiplexed, which is a fancy way of saying that one digit is lit at a time. Our persistence of vision will see all eight digits lit, however, if the scanning rate is fast enough. This technique greatly reduces power supply drain and just happens to be built into the 7030 chip. The 7030 implements this feature with an on-board digit-scanning generator that strobes the digits sequentially from left to right (digits 8 to 1) when a pulsing signal is input to pin 39. There is also a built-in digit-scanner oscillator requiring only an external capacitor between pins 39 and 40. Since the TBOD has a plentiful supply of signals, a 1-kHz signal was used for scanning, and it works well. A scan reset is needed, according to the 7030 data sheet, to avoid display damage and for leading-zero blanking. I used a 20-Hz signal, allowing 50 display scans before a reset blanks the display.

The result is a nice bright display with an almost imperceptible flicker. Faster scanning rates are possible, and faster resets will produce no visible flicker whatsoever, but the brightness will suffer. This is because the digit strobe duty cycle is only about 12%. The scanning-oscillator signal is divided into eight such sequential strobes.

These strobes, as MOS outputs, are not sufficient to drive display diodes directly. Instead, the strobes are sent to 75492 hex MOS-to-LED drivers, which have six drivers per package, each capable of sinking 250 mA.

The seven-segment information is similarly amplified by 75491s, which are quad MOS-to-LED segment drivers. The seven segments, labeled a–g, plus the decimal point, fully use two 75491 chips.

In a multiplexed display system, the seven-segment outputs are "daisy-chained" to all digits. That is, all the "a" segments for all the digits are wired together, and the "b" segments are wired to each other, and so on.

As the seven-segment information is sent to all those diodes, only the di-

odes in the digit that receives a strobe will light up.

A simplified pseudo-schematic could help illustrate this in Fig. 8. Assume that the three digits 8, 7, and 6 all have ones to be displayed. The active segment outputs from the 75491 are the "b" and "c" segments that will give a one when each digit is strobed. To forward bias the LEDs, the high pulse to the 75492 is inverted to a low, which will provide the proper bias solely for digit 8. The next strobe will activate digit 7 (turning off 8), and the next, digit 6 (turning off 7). All seven-segment information is synchronized by the digit strobes, and we see the result arranged as numbers 0–9. When the scan reset occurs, the scan oscillator restarts at position 8, the most significant digit.

One of the many economies resulting from display multiplexing is the elimination of the usual current-limiting resistors. They are not needed here because the scanning rate is sufficient to keep the average current through the LEDs at an acceptable level. A "direct drive" 8-digit display with decimal points could require 8 latches, 8 decoder drivers, and 64 current-limiting resistors. The overall brightness of the display may be varied by changing the supply voltage to the 75491 and 75492 devices and the scan rate.

The FND 500s are not as efficient as they are inexpensive, and the overall brightness was enhanced by using an 8-volt regulator, an LM340T-8, solely for the panel LEDs and the eight seven-segment display drivers.

If you decide to use different displays in your version, you will probably want to experiment a little with different voltages and scanning rates to optimize the display presentation to your liking. Fig. 9 shows the complete 8-digit wiring used in this counter.

The 7030 has a lamp-test input (pin 38) that, when brought high (+5 volts), will light all segments of all eight digits, showing all 8s. I couldn't resist putting a "lamp-test" push-button on the front panel for that purpose. The circuit used, though, does provide a useful function, because a counter overflow condition is also incorporated.

The 7030 has its three most significant decade overflow outputs for digits 8, 7, and 6 brought out to pins 14, 15, and 16, respectively, of IC1. Because this machine is an 8-digit counter, it made sense to use the eighth decade overflow output from pin 14 to set the overflow input latch at pin 13 of the 7030. An internal flip-flop holds the overflow indication until a counter reset (not a scan reset) occurs. As the overflow output becomes active, it sets the 4013 IC31 in the lamp-test circuit, causing a

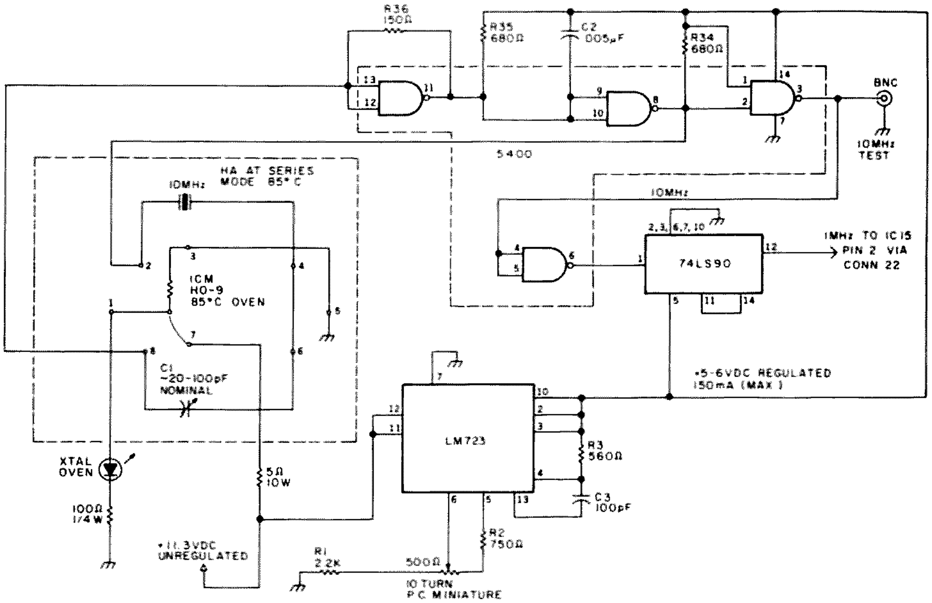

Fig. 5. Master oscillator.

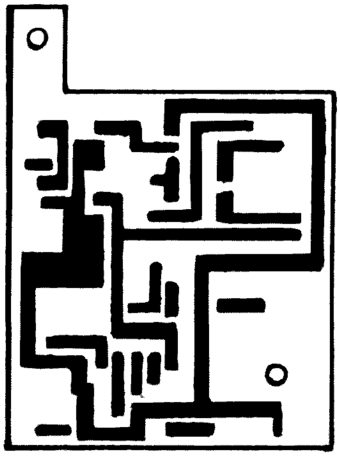

Fig. 6(a). Master oscillator PC layout.

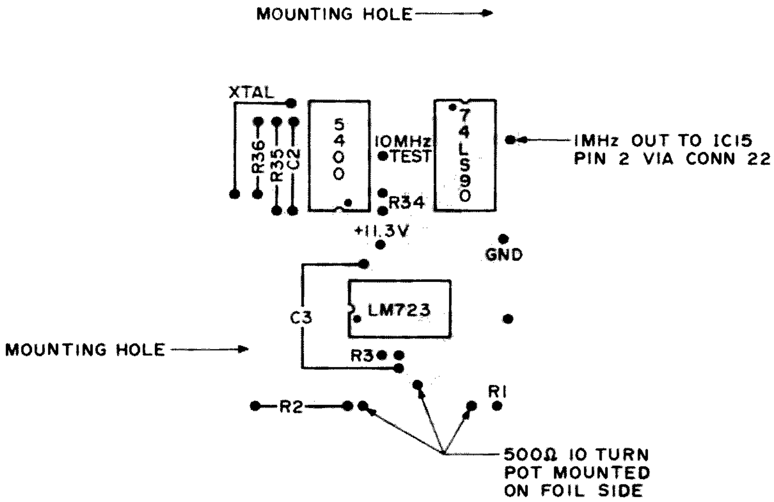

Fig. 6(b). Parts placement for master oscillator board.

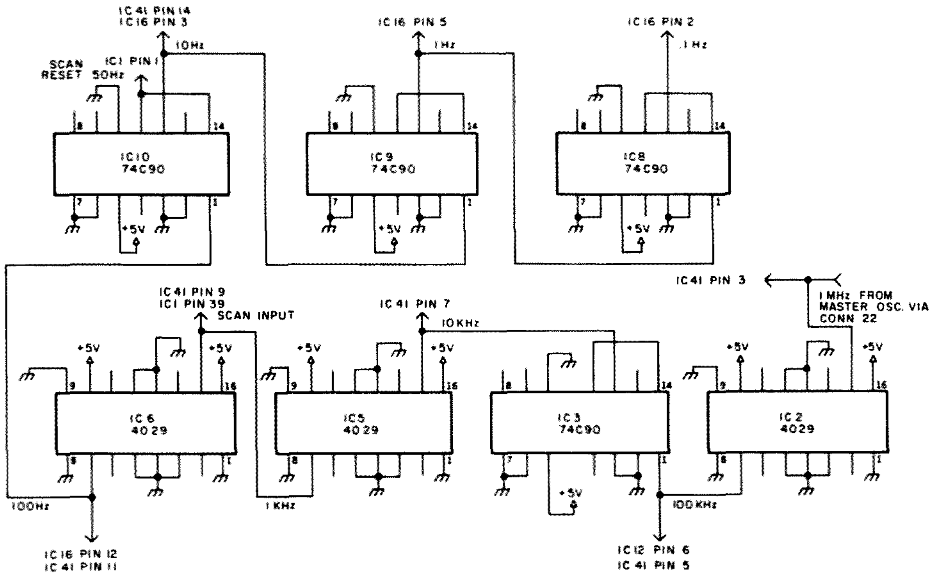

Fig. 7. Timebase oscillator divider chain.

display of all 8s. They will remain lit until the counter is reset. Should the overflow input be left unused, the counter display will "wrap around" to zero after 99,999,999 and begin counting again from zero. This probably wouldn't occur in frequency counting, but could be an important consideration in events totalizing.

The manual lamp-test push-button (as shown in Fig. 10) is connected to activate the lamp-test flip-flop (IC31) via the direct set input. An unused 74C00 gate is used as an inverter. The overflow latch output is sent to the data input, and when clocked by a convenient source (1 kHz here), it also activates the lamp test, separately from the previously-described manual operation.

This arrangement is only one of several possibilities, but it uses leftover gates and flip-flops. Other unused gates don't appear in the schematic, but have their inputs grounded. The CMOS doesn't like loose ends.

Counter Tactics

Now that the timebase and display have been described, let's journey into the bowels of the counter.

The counter has two inputs, in contrast to the simple demonstration example. These two inputs are shown with the gate controls in Fig. 11(a). The two input sources are conditioned to provide CMOS-compatible square waves that swing from almost ground to the supply voltage of +5 volts.

The PM line controls which of the two input signals is allowed through the remaining two input NAND gates of IC14. These comprise a 2-to-1 data selector; that is, the condition (GND or +5) of the PM line always enables one or the other, but not both, of the signals through the gates to finally output the signal to be counted on pin 6 of IC14. A low on the input of a NAND will keep its output high. Because of this, IC14 A and C will be controlled by the PM line with the aid of IC14 D, an inverter made from the remaining NAND gate. As the signal will suffer two inversions, whether through the path of IC14 C and B, or A and B, the output at pin 6 is logically identical to either of the selected inputs.

The input then goes to a 74C90, whose ÷10 output is used solely in the period mode, and then into a 74C157. The 74C157 is a device containing four 2-to-1 multiplexers that operate logically the same as the one formed by IC14. The 74C157 uses a single select line (pin 1) to route one of the two inputs for passage at a time. The two inputs A and B are shown for each of the four 2-to-1 multiplexers native to a 74C157. A high (or 1) level (~5 volts) on the select input chooses the B input for transmission, while a low (or 0) level (~GND) lets the A input pass.

Fig. 11(b) shows the gate synchronizer lifted out of the rest of the schematic for clarity. The input to the counter will *not* be the incoming frequency when the P (for Period) line is at a 1 level. For events totalizing and for frequency mode, the signal pulses are sent to a NAND gate (pin 4) and to the clock input (pin 3) of IC13, a 74C74 D-type flip-flop. The purpose of the other half of IC13 will be explained shortly.

Notice how the output of IC13, pin 5, is combined with the clock signal in the NAND gate accompanying pins 4, 5, and 6. This is the circuit that synchronizes the timebase with the input to eliminate the least-significant-digit jitter. The flip-flop "remembers" the timebase input at the pin 2 data input and transfers the rise or fall of the timebase signal to the Q output *only when clocked by the incoming event.* This timebase output enables the NAND gate, and the resulting output at pin 6 is the integer-valued pulse train that is counted by the 7030 at pin 32. The 7030 counts on the negative edge of the incoming signal, so NAND provides exactly the right combination of input and output levels. When the timebase at pin 5 falls, the output of the NAND goes high, shutting the gate to the 7030 counter.

This is an example of the

Signal	Source	Destination	Comments
1 MHz	Master oscillator Edge connector pin 22	IC41 pin 3	CMOS buffer
		IC2 pin 15	Input to TBOD
100 kHz	IC2 pin 7	IC3 pin 1	TBOD
		IC41 pin 5	CMOS buffer
		IC12 pin 6	Lamp test
10 kHz	IC3 pin 12	IC41 pin 7	CMOS buffer
1 kHz	IC5 pin 7	IC1 pin 39	Scan input for multiplexed display
		IC41 pin 9	CMOS buffer
100 Hz	IC6 pin 7	IC16 pin 12	Gate time .01 sec
		IC41 pin 11	CMOS buffer
20 Hz	IC10 pin 11	IC1 pin 38	Scan reset Resets display
10 Hz	IC10 pin 12	IC16 pin 13	Gate time 0.1 sec
		IC41 pin 14	CMOS buffer
1 Hz	IC9 pin 12	IC16 pin 5	Gate time 1 sec
0.1 Hz	IC8 pin 12	IC16 pin 2	Gate time 10 sec

Table 1.

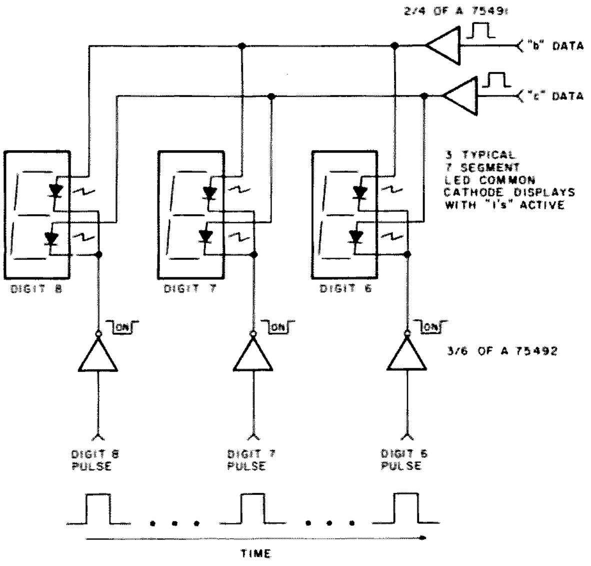

Fig. 8. Simplified multiplexed display example.

incoming pulses both starting and stopping the actual timebase at IC13 pin 2, which is shifted by the interval between event pulses. As long as this period of time between arriving pulses is longer than the difference between the propagation delay of the 74C74, the circuit will synchronize beautifully, allowing only whole numbers of pulses to be counted. This limitation is never realized because of the 5-MHz maximum count frequency into the 7030.

Page 208 in Don Lancaster's *TTL Cookbook* sparked my imagination and curiosity about eliminating the usual last-digit jitter found in most digital counting instruments. This ± 1 digit ambiguity is an error source that is inversely proportional to the measurement frequency. To keep the following example simple, let's assume a 1-second timebase. For a 10-Hz frequency, the ± 1 count results in a $\pm 10\%$ error per sample. At 100 kHz, the error decreases to $\pm .01\%$. If anyone wants an easily-forgotten formula, try this: % error = $\pm$ 100/(H $\times$ g), where H = frequency in Hz and "g" is the gate time in seconds. Notice that this particular source of measurement imprecision is in addition to timebase instability, noise, jitter in triggering, and all the other digital counter gremlins.

Now you can appreciate the slight cost of the couple of extra ICs to eliminate this error, especially for lower-frequency measurements. This important feature is overlooked by virtually all manufacturers of digital instrumentation in the hobbyist's realm.

If you are wondering about the other half of IC13, it is used to produce the proper duration of the timebase. Feeding pin 8 back to pin 12 gives a toggle action, dividing the incoming timebase by two. This gives a symmetrical signal high for the originally selected time, and then low for the same time. This "open gate" signal exits from pin 9 and then goes to the pin 2 data input of the previously-explained gate synchronizer.

A green LED on the front panel indicates gate interval. It is taken from IC13 pin 5, enabled by the AND gate in IC18 and driven from IC39, a 75492. A 220-Ohm resistor limits the current. An interesting side benefit is that uneven triggering of the gate synchronizer will show up as irregular flashing of the gate LED. This is a "poor man's" trigger-threshold indicator, since the incoming events must be continually starting the timebase and turning on the gate LED for reliable counting.

Remember the reset and update/load functions needed to make our ultra-simple counter accurate and convenient? Here's how they are generated in this counter.

The timebase representation from Fig. 3(a) will serve as a point of reference. Ideally, the load/update signal for the display should occur immediately after OPEN, at the beginning of

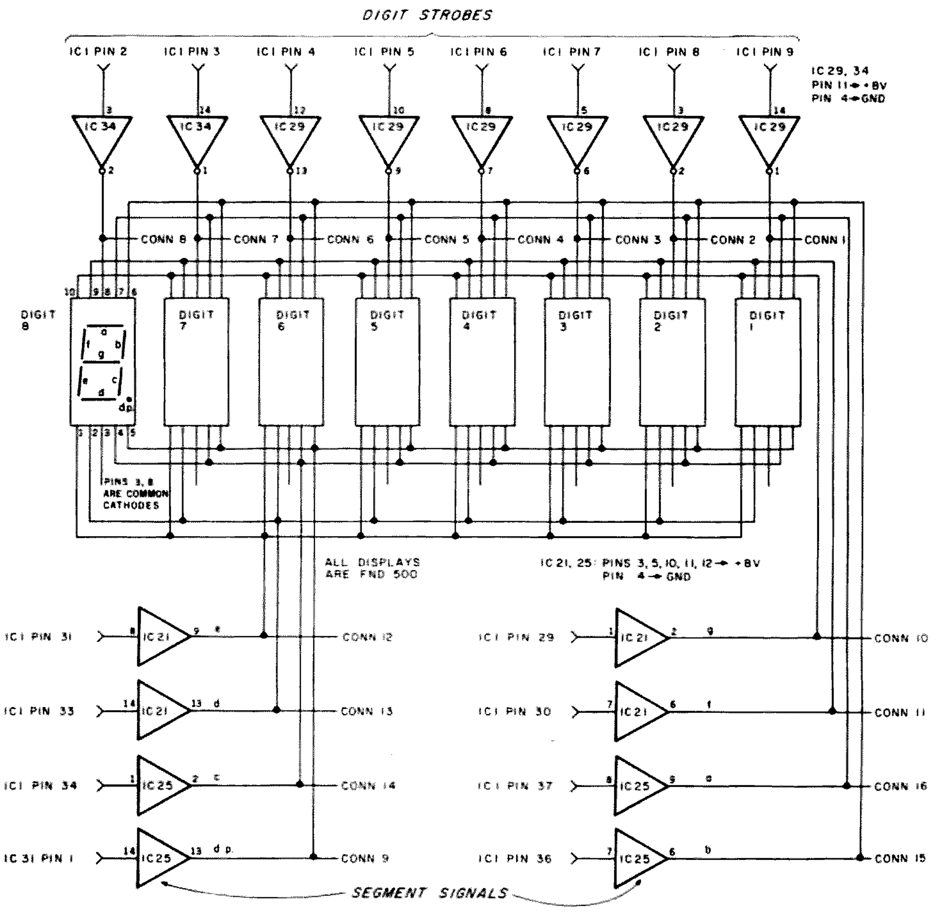

Fig. 9. Eight-digit multiplexed display.

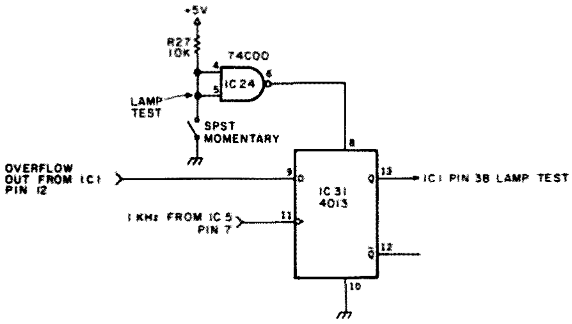

Fig. 10. Overflow lamp-test circuit.

CLOSE. The reset pulse should occur just prior to the start of the OPEN time, at the end of CLOSE time. We have to ensure that the 7030 is undisturbed for the entire prescribed interval, or the display will not be valid.

The load/update pulse is derived economically from the falling edge of the timebase Q_2 output of IC13 at pin 5. This signal is capacitively coupled through the parallel combination of C6 and C7 to the resistor network of R6 and R7. Normally held at +4 volts, the junction of all these components will dip low on the falling edge of the timebase. This "down" time is determined by the RC time constant of $C_6 + C_7$ (capacitive values add in parallel connections) and R_6/R_7. This is close to 15 μs for the values shown. The 7030 needs a load pulse of at least 12 μs to allow for internal settling.

The $\overline{\text{reset}}$ pulse is slightly more trouble. It cannot be taken directly from the rising edge of the count interval because that would result in a reset pulse occurring within the counting interval, destroying any hope of an accurate count. Not wanting to infringe on that accuracy, the $\overline{\text{reset}}$ has to occur *after* the load pulse, or the counter would display only zeros!

After some trial and error (mostly error), I discovered a combination that provides the properly-timed pulse. The successful circuit is shown in Fig. 11(b). Half of IC15 is used. The raw timebase frequency (before division by two) from the clock input (pin 11) of IC13 is enabled for the "no count" time by IC13 pin 6, which, of course, is the out-of-phase (opposite polarity) synchronized timebase. The resulting output at IC15 pin 11 is the inverse of what is needed, so it is inverted by the next NAND at pin 8. Events mode disables the $\overline{\text{reset}}$ by forcing a high output with a low at pin 9. The output at pin 8 is the needed high-to-low transition that occurs only during the no-count interval and not during events mode. From there it goes to the RC network where, similar to the $\overline{\text{load}}$ RC network, a brief negative pulse is generated. In this case it is about 5 μs, the proper duration for the 7030 $\overline{\text{reset}}$ circuitry.

In both these RC networks, the rising edge "glitch" will be ignored because of the bias level produced by the selected resistors and the forgiving characteristics of CMOS.

The mechanism for obtaining the period of the input is basically the same as the one used in the Elementary Counting section above. The timebase and the input signal are swapped with portions of a 74C157 doing the traffic direction. The input signals are first sent through IC7, a 74C90, for division by ten, and then through half of IC13 for an additional division by two. This gives a signal, now divided by twenty, that will become the "timebase" in period measurement. The P (for Period) se-

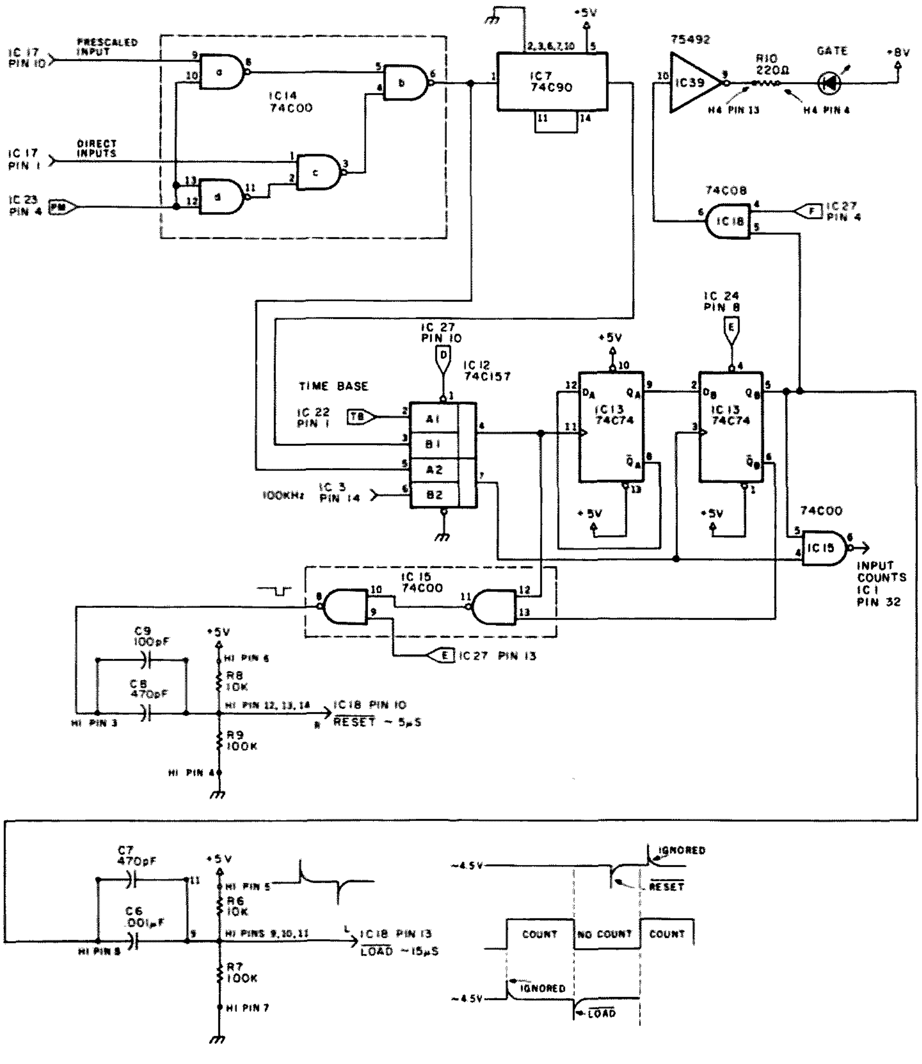

Fig. 11(a). Gate controls.

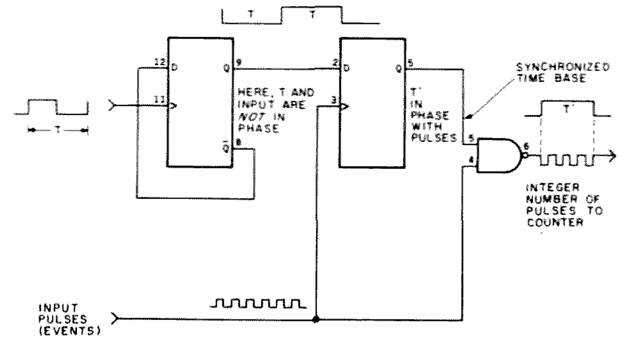

Fig. 11(b). Gate synchronizer.

lect line properly routes the B inputs of IC12 to accomplish this. When P is low, however, the A signals are digitally massaged to provide the normal frequency display.

Now that our period function has a timebase, the counter needs a source of pulses to count. A 50-kHz signal is picked off the TBOD chain. This frequency, when gated by a signal divided by twenty, gives a readout in microseconds. The $\overline{\text{load}}$ and $\overline{\text{resets}}$ remain the same as before.

The reason for prescaling the "unknown" low frequency is to reduce effects of noise on the input signal. Because low-frequency signals for which the period mode is used often are slow-rising leisurely functions of time, noise on the signal can cause false, premature, or late triggering of the counter. The random nature of noise can be put to use in the prescaling, or averaging, of the input signal. The uncertainty in triggering is reduced by the corresponding scale factor. This counter uses a factor of 20 for period averaging as a reasonable compromise between extreme precision and convenient utility.

The price to be paid for the averaging improvement is a correspondingly longer interval before the calculated period display is updated. For instance, if the period of a 20-Hz signal was directly measured, the updates would arrive every .05 seconds. Prescaling by 20 would divide the noise error by 20, but the display would be updated only every second (20 times .05 = 1 second). If your requirements dictate greater period averaging factors, more 74C90 dividers could readily be inserted into the period-measurement circuitry, with another pulse source chosen to give a display of the resulting period in μsec.

The events-mode operation of the counter only requires the withholding of the timebase and the subsequent resets of the counter. By having manual as well as automatic controls over resets and display updates in the counter, elapsed time/event functions are defined.

You're still here? Great! Next month I will cover the rest of the Universal Counter. We'll look at the front-panel design which features push-buttons rather than rotary-style switches. The counter's front end, decimal point, and power supply circuitry are waiting, too. Rounding out the story will be a discussion of construction techniques. Just why did I wire-wrap my counter? Read next month's article and find out. ■

HAM RADIO'S GOLDEN YEARS

When were ham radio's golden years? It probably all depends on when you first entered the hobby. My golden years were the 1960s: Benton Harbor lunch boxes, Allied catalogues, New York's radio row and the introduction of transistors. For others, the 60s may have meant incentive licensing, a declining ham population, and the first CBers hitting our bands. For me, however, those years will always be the sweetest.

This month's column is all about ham radio's golden years. I hope you'll find a question or two about your era.

ELEMENT 1—CROSSWORD PUZZLE
(Illustration 1)

Across

1) Old top ticket
7) Iran prefix
9) A traditional ham
12) A Zepp, for instance
14) Big time for traffic
16) Not ac (abbr.)
17) First tube
21) VHF rice container
23) Slang for 17 across
26) Iceland prefix
27) Amateur practice

Down

1) Commission before the FCC (2 words)
2) Plate current (abbr.)
3) No danger
4) Morse greeting (abbr.)
5) A satellite signal path
6) Bug maker
8) Old modulation (abbr.)
10) Signal way
11) Operates
13) Spark discharge
15) Ireland prefix
16) Morse slash
18) Contest double-copy
19) Finland prefix
20) Japan prefix
22) New electronics type (abbr.)
24) Transceiver
25) Morse double dash

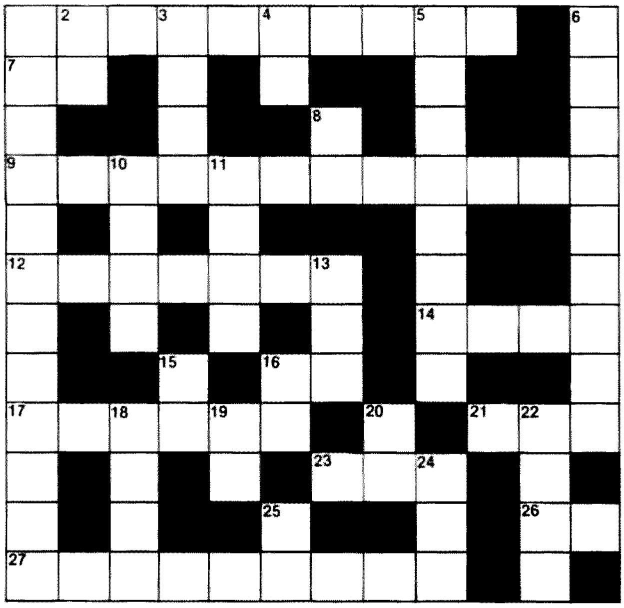

Illustration 1.

ELEMENT 2—MULTIPLE CHOICE

1) In 1958, Lee De Forest was asked by a reporter what would have been his reaction if transistors had suddenly been developed during the early years of the century. What did De Forest reply?
   1. "I would have fainted."
   2. "I would have invented the printed circuit board."
   3. "I might never have invented the audion."
   4. "Weren't they?"

2) What news did thousands of amateurs hear over their wireless sets on the night of November 8, 1916?
   1. News of the formation of the ARRL
   2. The first election night broadcast
   3. News of the sinking of the *Titanic*
   4. Word of the first transatlantic QSO

3) Remember those Fort Orange Radio ads that appeared in *QST* in the 1950s? In the ad, what was flying out the end of Uncle Dave's cigar?
   1. Lightning bolts
   2. Smoke
   3. Radios
   4. Money

4) Which year saw the introduction of the Hallicrafters SX-71?
   1. 1920
   2. 1934
   3. 1950
   4. 1958

5) In the introduction, I mentioned New York's "radio row." What stands on this site today?
   1. The new Madison Square Garden
   2. The Metropolitan Opera House
   3. Shea Stadium
   4. The World Trade Center

ELEMENT 3—TRUE-FALSE

	True	False
1) Howard Hughes was a ham.	______	______
2) The man who played Andy, on radio's "Amos 'n' Andy," was a ham.	______	______
3) The Conditional class license was phased out beginning in 1976.	______	______
4) In 1951, the US government forbade the ARRL to send its publications to the Soviet Union.	______	______
5) In its advertisements for the KWS-1, Collins claimed that SSB signals were "distortion free."	______	______
6) The 1947 WARC was held in New Jersey.	______	______
7) Novices have never had phone privileges.	______	______
8) The Heath Company got its start with "build-them-yourself" airplane kits.	______	______
9) NBVM was a popular operating mode in the 1930s.	______	______
10) A "Model 15" was a type of SSTV gear.	______	______

ELEMENT 4—SCRAMBLED WORDS

Unscramble these names of 1950s ham equipment manufacturers.

SNOHJNO	LINLCOS	IONTANLA	LAMCE
NORAS	SNEOGT	HTAIKHTI	

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—3 That Lee. What a wit.
2—2 The only problem was, the broadcast proclaimed Charles

Evans Hughes—instead of Woodrow Wilson—as the winner. Oh, well—guess they had to wait for the invention of the computer.
3—1 Forming the phrase "calling CQ." Love them rf cigars.
4—3 A staple for many Novices in the 1960s.
5—4 And I still feel bitter.

Element 3:
1—True. Yes, indeed. His call was 5CY.
2—False. Freeman Gosden, "Amos," was the ham.
3—True. To the dismay of cheats everywhere.
4—True. Wouldn't want the Russkies to get any of the League's precious secrets, would you?
5—True. No consumer advocates back then.
6—True. Atlantic City, to be precise.
7—False. They must have had the privileges back in the 1960s, or a lot of my friends were breaking the law.
8—True. Troubleshooting section: Plane flies backwards. Check motor polarity.
9—False. Baldwin's folly.
10—False. Better check "RTTY Loop."

Element 4:
JOHNSON, SONAR, COLLINS, GONSET, NATIONAL, HEATHKIT, ELMAC.

F	I	R	S	T	G	R	A	D	E	■	V

SCORING

Element 1:
Twenty-five points for the completed puzzle, or one-half point for each question correctly answered.

Element 2:
Five points for each correct answer.

Element 3:
Two and one-half points for each correct answer.

Element 4:
Three and one-half points for each correct answer.

How's your memory?
1-20 points—Erased
21-40 points—Faulty
41-60 points—16K
61-80 points—Sharp
81-100+ points—Golden Oldies!

FUN! MAILBOX

I feel I must point out an error in the True-False section of the May column. The Hazel episode that dealt with TVI showed a pretty good example of misunderstanding and jumping to conclusions. Mr. Baxter thought his TVI was caused by the ham—because his son was visiting the neighbor ham at the same time. Mr. Baxter also injured his back playing golf and was using a heating pad while he was trying to watch TV. At the end of the program an engineer from the electric company tracked down the TVI with an RDF unit. The heating pad had a bad thermostat and this was the cause.

Daniel L. Quigg WD4IRK
Lexington KY

You're absolutely correct. I'd like to say that I slipped in that question just to keep my readers on their toes, but I didn't. I goofed. For penance, I had myself strapped into a chair and forced to watch that episode 50 times on my VCR. As Hazel would say, "What a doozey!"—J. E.

READER'S CORNER

Well, I finally got around to checking the responses to February's Reader's Corner. The Magic Square's solution, not surprisingly, is "73." The following readers correctly guessed the answer: Frank Waldhaus WB1CSE, Dick Milewski N2ABA, Edward Baker N3CLP, Jim Higgens KB3PU, Bernie Lavezza N4FOC, Jim Morris WA6KGB, David Fox KA8CXQ, John Hufschmid KI9J, Dave Karr KA9FUR, Wayne Schuler AI9Q, I. Zender W9IQK, and Jerry Moore W0HMA.

Late arrival: Found one solution to January's DX puzzle—J. Edgar McDermott AH2K.

LETTERS

VIVA "QLF, OM"

I've been receiving *73* for 3 months now. So far, so good. I'm surprised to see someone agrees with my philosophies so extensively. Keep up the good work.

As far as getting more youngsters into ham radio goes, I think the key is reaching out more on their level: demonstrations in science classes and public places; offering classes in ham radio for beginners (WA3WKA and I have had several successful "graduates"); and finally just showing ourselves in a good light all the way around. And, of course, once the spark takes, it must be kindled with good examples from the old-timers. One of the reasons for some of the bad operating practices today is that the old-timers can't or won't put their feet down and correct a beginner's mistakes. (Is letting him develop into a lid doing him a favor? Viva QLF!)

Larry Gotts WA3UKC
Pleasant Mount PA

P.S. I'd sure like to catch you on the air, or for an eyeball sometime, Wayne. We'd have a lot to rag chew about!

Larry, you're right about getting teenagers interested. If they don't see amateur radio working, how can they get interested in it? Look for me around the low end of 20m phone. That's where I hang out when I get on.—Wayne.

RIGHT ON, WAYNE!

I have always wanted to drop you a line; renewal time seems to be a good time to do so. I have been following your articles, magazines, and other achievements since I was first licensed in 1959. You have not always been in the forefront of popularity, but you have usually been "right," and I have enjoyed all of it. I am a member of the ARRL and therefore feel that I am entitled to say whatever I wish. All organizations I have ever been associated with have benefited from criticism, and the ARRL should be no exception. I sometimes tire of those who at-

tack you or *73 Magazine* because you choose to change.

Change is usually for the better. I joined the ranks of amateurs in the middle of the furor over AM vs. SSB, a change for the better. The same happened on 6 and 2 meters, where I worked AM. Now we have a nice proliferation of repeaters. I remember the huge rock-mounted transmitters and now you could hold the modern equivalent in one hand. Drive on, Wayne! There are many loyal supporters in your "silent majority." You do grace the bands with your presence, and it is a pleasure to work you.

Mike Davis K4WYC
Durham NC

By golly, Mike, it has been a long time. Yep, I generated a lot of unfans when I pushed for sideband. More when I pushed for solid state in the 60s. Then a whole new bunch hated me when I pushed for FM and repeaters on VHF. I don't seem to be able to shut up and leave things alone. Oh, i grumble and beef when the FCC does something silly or bad for us... ditto when the ARRL does it... or Bash. But you know, there are a lot of hams... a whole lot... who agree about the FCC, agree about Bash... and then get furious when I mention the ARRL. No, you can't be honest about them or try to put 'em into perspective. It's like religion and politics, a matter of emotion and to hell with facts. Guess I'll never learn to keep my mouth shut or my typewriter turned off. Thanks for sticking with me for so long, Mike.—Wayne.

IDIOTS?

After years of being interested in ham radio from afar, last year I got with it and got my license. I find the technology fascinating, but it wasn't long until I became disenchanted with the content of the QSOs on the air. Banal ramblings which go on and on and on yet say nothing... excruciatingly redundant callsign exchanges with every transmission... and, of course, the very prevalent "CB syndrome," which manifests its presence with seemingly uncontrollable overmodulation and heavy breathing in the mike. Idiots. I thought that there was intelligent life on the ham bands. There are exceptions, of course, but it seems like hardly anyone wants to discuss anything of any consequence. Has it always been like this?

Keith Orosz N6FQE
Seal Beach CA

Intelligent life on the ham bands? Surely you are jesting! No, as a matter of fact, though it is hidden from casual detection, it is there. But I have some bad news for you... it will rarely show its head. The fact is that before you will discover intelligence, you have to exhibit it. I realize that this is a painful fact to face. Keith, I've been hamming for a long time now and I manage to find interesting people to talk with. Often. Oh, I agree that there are some hams who are almost without redeeming qualities. There are some who are so afraid of talking that the best you can get is an antenna discussion, which is not one of my favorite topics. Keith... if you look hard and work out ways of getting through the layer of insulation, you'll find absolutely fascinating people who will enjoy talking with you. There are a thousand things I enjoy talking about. I give hints about some of them in my editorials. I'm alive with information, ideas, interesting experiences... and yet hundreds... perhaps thousands... of hams have contacted me without ever giving either of us a chance to enjoy the contact. Thousands have contacted me and had a contact to remember. It's all in you, Keith, not us.—Wayne.

MORE ABOUT CHARLIE

Upon returning from a meeting of the Montserrat Amateur Radio Society last night, I opened your magazine (which had been given to me that day) and I found your article "Messages from Station Charlie."

During the war, I was a member of the Women's Transport Service, F.A.N.Y., and I was stationed both at the camp shown in the photograph and also at another nearby station. I was a W.T. operator. I was able to recognize the faces in the picture, but unfortunately I was unable to put names to the faces.

It may interest you to know that the Special Forces Association Signals Section is still very much a group, having a newsletter published every four months and meetings twice yearly. Several of the members are still operating.

I will be writing to the Association to tell them all about the article. I thank you for helping me to contact the people mentioned in the article.

Ursula M. Sadler
Montserrat, West Indies

FIRST-CLASS TAPES

I passed my amateur Extra exam last week in Atlanta and would like to extend my thanks for your first-class code practice tapes. My only complaint is that the text proved to be so much easier than the random groups on the tape that I could have gone a couple of weeks earlier! Hi.

Alan P. Biddle WA4SCA
Huntsville AL

Sure, Alan, you could have gone earlier... but I wanted you to be so good at the code that you would not freeze up when faced with the test. By making you able to copy far faster than needed, you probably found yourself feeling confident when the code test started... and able to go right on through it with no problem. Remember that with the old-style code test, you had to copy only one minute solid of that test, but with the new one if you don't get the whole test solid, you can get tripped up by one of the questions. No, you want to have that code sound slow when you sit down to copy it and that's what my tape does for you.—Wayne.

CRANKY CURMUDGEONS?

As a new ham, here are a few observations on this wonderful world of amateur radio. But first: I am retired, having been a professional pilot and a businessman for, well, a long time.

I received my Novice license in November, 1981, my Technician this past February, and plan the General soon. Ham radio was a natural selection since my fascination with electronic things began with watching the old Collins airborne transceivers whir and grind to produce some new frequency that would let you talk to where you were going. That was especially nice if you had been flying over water for about 8 hours. But enough of that or shortly I'll be talking Ford Tri-motors.

So, what is this piercing clarity I propose to offer about amateur radio? First, that I like it very much. The logic of the licensing program (learn and work code as a Novice; upgrade for additional privileges) seems too delicious to have been government-produced. And the things you hear about meeting great people on the air are really true.

But I am dumbfounded at the customer relations to be found in a radio store. Passing the FCC tests is a minor part of becoming a ham. The big thing to learn is how to get along with the omniscient, crotchety people who sell the radios.

Perhaps I can never achieve the stature of these Ancient Icons, but, boy, I really tire of the idiot treatment. And if I am not received as an imbecile, I am labeled an intruder wantonly invading the A.I.'s busy-work-destroying thoughts of dreadful complexity.

I really feel that a person using the simplest sales technique (be cheerful, knowledgeable, helpful) could walk off with the business.

These observations don't emanate from just one store. They include everybody. Wayne, you have sagely said that amateur radio needs new blood. I think the first new blood to hit the sales end of hamming will blow the curmudgeon contingent right out of the water. I would not weep.

But I love the rest of it. I really do. I guess that's really why I wrote this letter.

R. J. Richardson KA6RJJ
Burbank CA

Hey, is R. J. right about this? I have been so well received in the ham stores I've visited that I am not a good judge of what the newcomer faces. How about some letters from readers which might help ham dealers understand what is going on... and how to fix it?—Wayne.

RAG-CHEW AWARDS

After having read and appreciated your editorials for several years, two ideas come to mind for your or anyone's consideration.

First off, why doesn't someone establish an award for DX rag chewing? I can't do it myself. Say the minimum qualifica-

tions to be a half-hour QSO on phone or SSTV or fifteen minutes on CW or RTTY with one ham from each of 100 countries. Additional endorsements could be for conversing with a second ham in each of the same 100 countries or for each of the 100 QSOs to be in the DX ham's native tongue. The certificate awarded should be suitable for the effort involved; 25-50 hours as a minimum amount of time requires brass plaques on walnut or similar cetificates.

Second, I strongly suspect that there is a huge demand for radios with an amateur appearance, especially in the 2-meter FM field. By amateur appearance, I mean big, bulky, ugly boat anchors with a myriad of gauges, knobs, levers, handles, and hasps rather than miraculous, neat little units which could fit in a shirt pocket. I find nothing wrong with the neat units on the market, but somehow I think that non-hams expect us to show up with boat anchors. Recently, at an emergency communications center, after just seeing the neat little boxes, a person in control referred to the hams in attendance as a group of CBers. Major bloodshed was averted only by heroic efforts.

So maybe I'll buy a big, ugly, military surplus chassis and stuff it with a 2-meter rig, power supply, thermos for coffee, and a cooler for the beer. I'll hang some gauges on it and be prepared for the next emergency.

Chris Creasy III WB3AAM
Catawissa PA

Chris, I used to have an award for long-winded folk like me. It was the Real Rag Chewers Club (RRCC) and one had to talk with a station for at least six hours to get the award. Several hundred were awarded.—Wayne.

BANGING CODE

First off—keep gunning! Amateur radio needs awakening if it's to continue as a living, growing service.

i agree with you about the relaxed technical standards needed for a given license. I am not a ham—I have an A.A.S. in electronics and am taking a General class study class that the Kalamazoo amateur club offers. I was totally surprised at how little I had to know about electronics to pass a test! The code should be an added privilege (frequencies w/ license grade)—not a requirement for a license. Most newer hams are more interested in interfacing a computer to their rigs, ATV, microwaves, etc., than banging code. I'm having trouble learning the code and may have to settle for a Technician's license, which would be OK since my main interest is with the possibilities available to me at VHF and above.

Once again, Wayne, keep rattling the cage, and let's both hope the Amateur Radio Service lasts long enough for the old blood to pass on and the newer aspirations of innovation come into control to "pressure" the FCC into awakening.

John E. Allgaier, Jr.
Kalamazoo MI

YES TO CODE

I think you are wrong about a code-free test for a ham ticket.

I am 75 years old and I passed the code test 3 years ago with no problem. The main reason you want to get more hams on the air is to sell more of your magazines and books.

The biggest reason why more people don't go ham, is the cost.

Instead of all the adds for TV satellite material, print more plans for low-cost transmitters and receivers for beginners.

I have had a lot of young people talk to me about ham radio and when you tell them what it costs to start, they lose interest.

I have contacted most of the European countries with only 30 Watts output.

I am sure some of the companies could put out low-priced sets for people who can't afford $700 to $2,000.

Yes, most of the people who take the Bash Test pass. But 2 days after the test, they couldn't answer one simple question on theory.

What we need is a way to get young people interested.

I am willing to give free code lessons and simple theory to anyone in my area.

If other hams would do this, I am sure it would work. Keep the CW.

R. Spencer KA1CEV
Franklin MA

So the whole thing is a con to sell magazines, eh? You sure are a nasty one, Spencer. And with HTs costing a couple hundred dollars, I'm not as convinced as you about money being any serious problem. Indeed, it has been my experience that kids seem to have little trouble getting the money they need for drugs and cars, so perhaps ham gear would not be that difficult if they were interested. My high school informants are adamant when they say that it is the code which is turning the kids off. They want to know why they should learn the code to operate phone, RTTY, slow scan, and so on. I don't have a rational answer for them. And I note that the FCC seems to be going in the same direction, with a dropping of the code requirement for the Tech ticket a good bet. By the way, Spencer, a couple of companies did put out low-cost low-band rigs and no one would buy them.—Wayne.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

NEW JERSEY QSO PARTY
2000 GMT August 14 to 0700 GMT August 15
1300 GMT August 15 to 0200 GMT August 16

The Englewood ARA invites all amateurs worldwide to participate in the 23rd annual NJ QSO Party. Phone and CW are considered the same contest. A station may be contacted once on each band. Phone and CW are considered separate "bands," but CW contacts may not be made in phone band segments. NJ stations may work other NJ stations, and NJ stations are requested to identify themselves as "DE NJ".

EXCHANGE:

QSO number, RS(T), and ARRL section, country, or NJ county.

FREQUENCIES:

1810, 3535, 3900, 7035, 7135, 7235, 14035, 14280, 21100, 21355, 28100, and 28610. Suggest phone activity on the even hours; 15 meters on the odd hours (1500 to 2100 GMT); 160 meters at 0500 GMT.

SCORING:

GEARVAKf
—BULLETIN—

NEWSLETTER CONTEST WINNER

For more than 22 years, the *GEARVAKf Bulletin* has inflicted its own peculiar brand of madness on the world of amateur radio newsletter publishing. It's time the *Bulletin* received recognition for its many journalistic achievements.

Founded sometime in the murky past by the very distinguished Dr. Felix R. Onehundredton, GEARVAKf is more properly known as the Greater Enon AmateuRadioVention And Kite fly (the "f" is silent). Depending solely on reader contributions, this august society produces one and sometimes two issues of its amusing *Bulletin* each year.

The *GEARVAKf Bulletin* strives to cover stories which are overlooked or ignored by traditional amateur journals. Two years ago, for instance, the *Bulletin* broke the exclusive story of the raging fire that nearly destroyed the 20-meter band. A follow-up article detailed FCC plans to install a sprinkler system to guard against future conflagrations.

Strong technical content is a hallmark of the *GEARVAKf Bulletin*. The newsletter has published pioneering articles on such diverse subjects as the Exploding Rat Amplifier and the early closing of the 10- and 15-meter bands due to FCC budget cuts. The exploits of researchers such as Dr. Phugoid G. Dutchroll keep GEARVAKf at the cutting edge of technology.

The *Bulletin* frequently publishes the results of GEARVAKf member polls, which are conducted by the GEARVAKf Public Opinion Subcommittee. Members were asked recently, "How do you feel about current issues?" Fully 84% voted "no," with 11% "yes" and 5% "undecided" about current issues. That says it all.

For wackiness above and beyond the call of duty, editor/ringleader K8DMZ and his cronies deserve heartiest applause. Congratulations to our newsletter of the month, the *GEARVAKf Bulletin*.—WB8BTH.

RESULTS

3RD ANNUAL 160-METER SSB CONTEST*
(Claimed Scores Over 100,000)

SINGLE OPERATORS:

Callsign	QTH	Claimed Score
W9RE	IN	371,580
W8LRL	WV	350,700
WB3GCG	MD	322,660
WB8JBM	OH	315,315
W1CF/1	MA	236,260
WD8CRY	MI	234,240
WBØCMM	CO	230,895
KJ9D	IN	184,670
KC8P	MI	169,800
N5IJ	TX	169,650
N8ATR	OH	164,640
K9QLL	IL	160,950
WØCM	KS	147,600
K9RJ	IL	142,500
KB8HW	MI	138,320
N5CG	OK	135,810
W3BQN	PA	135,730
W9DUB	WI	135,660
KC4OV	TN	130,140
K1MNS	NH	120,725
K1LPS	VT	119,610

KØSTI	SD	109,080
W4VKK	GA	106,020
W2FJ	NJ	104,430
N7DF	UT	103,880
N4IN	FL	101,100

MULTI-OPERATOR:

Callsign	QTH	Claimed Score
W8NGO	MI	273,900
W4CN	KY	238,950
AK2E	NY	224,750
K9ZUH	IN	213,280
K9YUG	IL	152,400
K9ZX	IL	130,560

Full details and final scores will be featured in a future issue of *73*. Well over 1,000 stations competed—the best year EVER!

sponsored by *73 Magazine

the number of complete contacts with NJ stations by the number of NJ counties worked (21 maximum). NJ stations count 1 point per W/K/VE/VO QSO and 3 points per DX QSO. Multiply total QSO points by the number of ARRL sections (including NNJ and SNJ; maximum: 74). KP4, KH6, KL7, etc., count as 3-point DX contacts and as section multipliers.

AWARDS:

Certificates will be awarded to the first-place station in each NJ county, ARRL section, and country. In addition, a second-place certificate will be awarded when 4 or more logs are received. Novice and Technician certificates will also be awarded.

ENTRIES:

Logs must show date/time in GMT, band, and emission. Logs must be received not later than September 11th. The first contact for each claimed multiplier must be indicated and numbered and a check list of contacts and multipliers should be included. Multi-operator stations should be noted and calls of participating operators listed. Logs and comments should be sent to: Englewood Amateur Radio Assoc., Inc., Post Office Box 528, Englewood NJ 07631-0528.

A #10 size SASE should be included for results. Stations planning active participation in NJ are requested to advise the EARA by August 1st of their intentions so that they can plan for full coverage from all counties. Portable and mobile operation is encouraged.

EUROPEAN DX CONTEST—CW
Starts: 0000 GMT August 14
Ends: 2400 GMT August 15

Sponsored by the Deutscher Amateur Radio Club (DARC). Only 36 hours of operation out of the 48-hour period are permitted for single-operator stations. The 12 hours of non-operation may be taken in not more than three periods at any time during the contest. Operating classes include: single-operator, all-band and multi-operator, single-transmitter. Multi-operator, single-transmitter stations are only allowed to change band one time within a 15-minute period, except for making a new multiplier. Use all amateur bands from 3.5 through 28 MHz. A contest QSO can only be established between a non-European and a European station. Each station can be worked only once per band.

EXCHANGE:

Exchange the usual six-digit number consisting of RST and progressive QSO number starting with 001.

SCORING:

Each QSO counts 1 point. Each QTC (given or received) counts 1 point. The multiplier for non-European stations is determined by the *number of* European countries worked on each band. Europeans will use the last ARRL countries list. In addition, each call area in the following countries will be considered a multiplier: JA, PY, VE, VO, VK, W/K, ZL, ZS, UA9/UAØ. The multiplier on 3.5 MHz may be multiplied by 4, on 4 MHz by 3, and on 14 through 28 MHz by 2. The final score is the total QSO points plus QTC points multiplied by the sum total multipliers.

QTC TRAFFIC:

Additional point credit can be realized by making use of the QTC traffic feature. A QTC is a report of a confirmed QSO that has taken place earlier in the contest and is later sent back to a European station. It can only be sent from a non-European station to a European station. The general idea is that after a number of European stations have been worked, a list of these stations can be reported back during a QSO with another sta-

tion. An additional one-point credit can be claimed for each station reported.

A QTC contains the time, call, and QSO number of the station being reported, e.g., 1300/DA1AA/134. This means that at 1300 GMT you worked DA1AA and received number 134. A QSO can be reported only once and not back to the originating station. Only a maximum of 10 QTCs to a station are permitted. You may work the same station several times to complete this quota, but only the original contact has QSO-point value. Keep a uniform list of QTCs sent. QTC 3/7 indicates that this is the 3rd series of QTCs sent and that 7 QSOs are reported. Europeans may keep the list of the received QTCs on a separate sheet if they clearly indicate the station that sent the QTCs.

AWARDS:

Certificates to the highest scorer in each classification in each country, reasonable score provided. Continental leaders will be honored with plaques. Certificates will also be given stations with at least half the score of the continental leader or with at least 250,000 points. The minimum requirements for a certificate or a trophy are 100 QSOs or 10,000 points.

ENTRIES:

Violation of the rules, unsportsmanlike conduct, or taking credit for excessive duplicate contacts will be deemed sufficient cause for disqualification. The decisions of the Contest Committee are final. It is suggested you use the log sheets of the DARC or equivalent. Send a large SASE to get the wanted number of logs and summary sheets (40 QSOs or QTCs per sheet). SWLs apply the rules accordingly. Entries should be sent no later than September 15th to: DARC DX AWARDS, PO Box 1328, D-895 Kaufbeuren, West Germany.

EUROPEAN COUNTRY LIST:

C31, CT1, CT2, DL, DM, EA, EA6, EI, F, FC, G, GC Guer, GC Jer, GD, GI, GM, GM Shetland, GW, HA, HB9, HB0, HV, I, IS, IT, JW Bear, JW, JX, LA, LX, LZ, M1, OE, OH, OH0, OJ0, OK, ON, OY, OZ, PA, SM, S, SV, SV Crete, SV Rhodes, SV Athos, TA1, UA1346, UA2, UB5, UC2, UN1, UO5, UP2, UQ2, UR2, UA Franz Josef Land, YO, YU, ZA, AB2, 3A, 4U1, 9H1.

A5 MAGAZINE FSTV UHF CONTEST

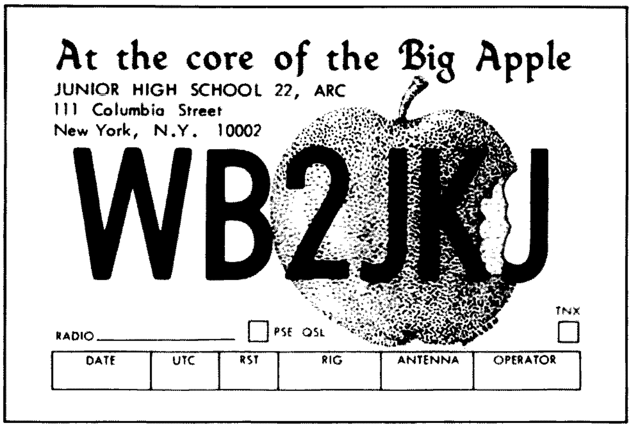
Starts: 1800 EDT August 20
Ends: 1800 EDT August 22

Over $750 worth of prizes will be awarded in the 1982 *A5 Magazine* North American FSTV UHF Contest. This 48-hour ATV contest is designed for the UHF specialized communications operator to work as many FSTV contacts as possible with rewarding bonus multipliers and additions for quality picture transmissions, DX distance accomplishments, and bands utilized. All ATV stations in the United States, Canada, and Mexico are eligible for entry. Even stations without transmit capability can participate utilizing a secondary frequency for voice confirmation of received video. Please note that dates and times are in Eastern Daylight Time (EDT).

Contacts must be made on authorized amateur bands and within power limitations as set forth by the governing agency. Transmission of TV signals in recognized SSB, EME, FM, or satellite portions of the UHF bands will not be recognized and becomes grounds for immediate disqualification of entry. No station may claim another station more than one time per band. Crossband contacts are encouraged and authorized.

Portable, mobile, and airmobile, etc., contacts are allowable as long as verification of location and simplex transmission is used. Contacts via repeaters or any type of relaying device are prohibited. This is not to discourage ATV repeater use, but merely to establish operator and station self-accomplishment. Secondary audio frequencies for signal coordination are recommended, such as 146.43 MHz FM, 7.290 MHz, and 3.990 MHz. Any locally-utilized secondary voice frequency may be used.

For a valid contact to occur, verification must be established by both the receiving and transmitting stations. This can be accomplished by video return, voice communications, hardcopy photography, or lettered QSL. Proof of contact to be included as logbook entry with required information or enclosed photographs to *A5*.



QSL OF THE MONTH: WB2JKJ

Joe Fairclough WB2JKJ had this to say:

I am a Junior High School English teacher and have been since 1968. I have been an amateur operator since 1962.

After several years of using the conventional methods of teaching English and finding they simply do not work on the 7th and 8th graders I'm dealing with, I decided it was time for a change. There had to be a better way. If a child is interested and *wants* to be in school, he will learn.

With the idea of creating interest and excitement, I took the standard English curriculum and revised it all around ham radio. Very basically and briefly, this is what I developed:

1. Teach the children Morse at the beginning of the term and get them to a point at which they can copy their spelling and vocabulary in CW.
2. Use the Novice handbook as the class textbook. Diagram its sentences, examine its parts of speech, etc.
3. Reading assignments from *73*, *QST*, *CQ*, and any other suitable publications.

Our program receives no funds from any government agency or even the school itself. We are totally self-supporting. All our equipment was purchased from the fund-raising efforts of the students and myself. Even down to the postage, it's all done by the kids. It's very difficult to survive this way, but it makes for a great spirit of everyone pulling together, and besides, hams are great people and without them, this wouldn't be possible.

So listen for us on 15. We'll be listening for you.

RESULTS

1982 SSTV CONTEST RESULTS

Activity during this year's SSTV contest was relatively mild, but there were indications of video enthusiasm and acceptance by amateurs on the bands. Slow-scanners were noted on several HF bands, many exchanging reports via color rather than black-and-white SSTV. Quite often, we also noticed contest activity giving way to general-interest SSTV views and idea exchanges. Great! If such interests are sparked and a general attitude of friendship developed, a worthwhile purpose is definitely served. DX signals poured into the US on both 10 and 20 meters during the contest's morning periods, and again during the last hours of each day's operation.

We've received requests for shifting the SSTV contest period from April to January or February (its close proximity to Dayton in April creates a "strain" on contesters). What's your opinion? Another item of interest concerns holding "crossband" SSTV activities between Advanced class and General class SSTVers during the first 15 minutes of each contest hour. Let's hear your opinions either via mail or via the Saturday SSTV net—and soon. Announcement deadlines for the next contest are nigh. Truthfully, we must show more contest participation, gang, or the contest will be doomed to failure. We know many of you operated, but where are those logs?

This year's SSTV contest winner was Mike Di Persio KC2Q, of Bradley Beach NJ. Congratulations, Mike, and enjoy your year's subscription to 73.

Thanks to all for the participation, and we look forward to your support next time. See you on the Saturday SSTV net (1800 UTC, 14,230 kHz).

Dave Ingram K4TWJ
Richard "Brooks" Kendall W1JKF

Video pictures transmitted must contain as a minimum the station callsign and location along with a signal report of the video received. Standard "P" signal reports will be used.

Quality multipliers, DX distance additions, and band usage multipliers will be used as shown later. Standard air or road maps may be used to determine recorded distances. A circle radius should be drawn from the location of the operating station with increments of 25 miles and dots showing locations of stations worked. The map used must be submitted to the *A5 Magazine* contest editor along with all log entry information.

Winners with the highest score in each US call area, Canadian province, or Mexican XE1, XE2, or XE3 areas will receive a free one-year subscription to *A5 Magazine*, a copy of the new ATV book *Everything You Always Wanted To Know About ATV But Were Afraid To Ask*, and a gold Specialized Communications Achievement Award certificate suitable for framing. All entries, regardless of placement, will receive a gold certificate showing participation. The highest-scoring North American winner will also receive a wooden plaque engraving with a large orthodon video tube similar to the *A5 Magazine* Good Image award, along with his photo in *A5 Magazine.*

All entries are encouraged to send photos of station operation and contacts received which will be returned by *A5 Magazine.* Entries must be postmarked no later than September 1st, allowing one week for lettered verifications. All logs will be returned. Please include *A5 ATV Magazine* subscription expiration date information with your entry.

SCORING:

The base points awarded are determined by the type and strength of signal received. Many times on long distance contacts or weak band conditions, only the sync bar level is seen, without a video picture. If indeed verification can be accomplished by both stations on a secondary frequency utilizing the "on-off" method with the receiving station stating the actual "on-off" reception test signals, then low-level points can be achieved. It is to the advantage of both stations to watch the bands or apply more power to obtain a better-quality contact with higher points. Continued quality upgrades, including color reception with sound, enhance higher point totals. In case of better conditions further along in the contest, previous claimed contacts may be erased and upgraded if desired.

FSTV UHF CONTEST SCORING

Base Point Table

Points	Contact Type
1	1-way, verified sync or audio tone bar display
2	2-way, verified sync or audio tone bar display
3	1-way, audio sound detected only (subcarrier or on-carrier)
6	2-way, audio sound detected only (subcarrier or on-carrier)
10	1-way, video picture (b&w) detected
15	1-way, video picture (b&w) detected with sound
20	2-way, video picture (b&w) detected
30	2-way, video picture (b&w) detected with sound
40	1-way, color picture detected
45	1-way, color picture and sound detected
80	2-way, color picture detected
85	2-way, color picture with sound

Picture Quality Multipliers
(Base point times P signal quality level)
Base times 1 = P-0 to P-1 picture
Not usable, lost in noise, limited use
Base times 2 = P-2 picture
Passable picture, high noise level
Base times 3 = P-3 picture
Fair picture, noticeable noise
Base times 4 = P-4 picture
Good picture, slight noise visible
Base times 5 = P-5 picture
Excellent, closed circuit, no noise visible

DX Distance Addition
(Base point times P-signal quality multiplier plus DX points)
Note: Distance figured in miles and rounded to nearest 25-mile marker. Plus 25 points for 25 miles, 50 points for 50 miles, 75 points for 75 miles, etc.

Band Used Multipliers
(Base times P-signal multiplier plus DX times band used)
1200 MHz = times 2
2300 MHz = times 3
Higher frequencies = times 4

OHIO QSO PARTY
Starts: 0000 GMT August 28
Ends: 2400 GMT August 29

Sponsored by the Cuyahoga Falls Amateur Radio Club, the contest is open to all radio amateurs worldwide.

EXCHANGE:

RS(T) and ARRL section, DXCC country, or Ohio county.

SCORING:

Score 2 points for each contact with an Ohio station. Contacts with a Falls member will be worth 10 points and contacts with W8VPV, the club station, will count 25 points. Outside Ohio, multiply your total QSO points by the number of Ohio counties worked on all bands. Ohio stations will score 5 points for out-of-state contacts plus the member and club station bonuses. Multiply your QSO point total by the sum of counties (max.: 88), ARRL sections (max.: 74), and DXCC countries on each band. Phone and CW are considered two bands.

AWARDS:

Plaques to the top station in Ohio and outside Ohio. Certificates to the top station in each ARRL section, Ohio county, and DXCC country. All awards will be made out to the station call on the entry.

ENTRIES:

Each log must show the date/time in GMT, band and mode, and the complete exchange. A copy of the official log sheet and reporting form are available from the club by sending an SASE. Dupe sheets must be completed for any stations with more than 200 contacts. Some form of summary sheet showing the scoring and usual signed declaration are also requested. Send a large SASE for a copy of the results. Deadline for logs is Sept. 29th. All entries and requests for forms/logs should be addressed to: The Cuyahoga Falls ARC, PO Box 6, Cuyahoga Falls OH 44222.

OCCUPATION CONTEST
Starts: 1800 GMT August 28
Ends: 2400 GMT August 29

The Radio Association of Erie PA is sponsoring their second annual contest. The contest is open to all amateur radio operators.

EXCHANGE:

RS(T); occupation; and state, province, or country. Please try to keep occupations in general fields such as engineer, technician, machinist, salesman, etc.

FREQUENCIES:

CW—50 kHz from the bottom of the ham bands. Phone—50 kHz from the top of the ham bands. Repeater contacts are not permitted.

SCORING:

Count 1 point per QSO, with multipliers determined by the number of similar occupations worked. One multiplier point is given for every 3 similar occupations. Final score is the product of the QSO points times the total multiplier.

AWARDS:

A plaque will be given to the top-scoring station. Certificates for the top stations in each state, province, and country.

ENTRIES:

The mailing deadline for logs is Oct. 1st. They are to be sent to: Chris Robson KB3A, 6950 Kreider Rd., Fairview PA 16415.

HAM HELP

I would like to know if the speaker-microphone SMC-24 is available for the Kenwood TR-2400 2-meter HT from a commercial distributor or an individual.

Stephen J. O'Malley N2CLE
35-54 169 Street
Flushing NY 11358

I am looking for any information on the Bendix Aviation Corp. Model 2V13E 450-MHz FM mobile radio—particularly the manual and schematic.

NEW PRODUCTS

LINEAR AMPLIFIER

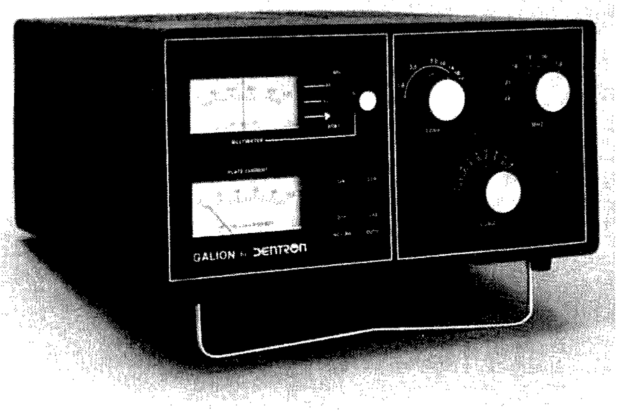
A 1200-Watt SSB, 1000-Watt CW linear amplifier covering 160, 80, 40, 30, 20, 17, and 15 meters is available from DenTron Radio Co.

The "Galion" amplifier features a rugged, reliable 3-500 grounded grid triode, full-function metering, and internal in-out switching. A built-in dual power supply allows it to operate from either 120- or 240-V ac lines while reduced voltage tune ensures peak efficiency regardless of mode. The Galion amplifier includes a tuned input circuit for compatibility with either solid-state or tube-type exciters of any manufacturer.

Improved reliability and performance are provided through an exclusive linearity test circuit, which instantly verifies proper tune-up and operation, and a two-speed blower to provide high volume cooling capacity.

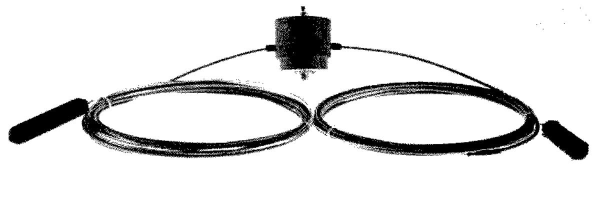
A modification kit available for the Galion amplifier will extend frequency coverage to the 12- and 10-meter amateur bands and associated MARS frequencies. The Galion amplifier is priced at $695.

For more information on the Galion linear amplifier, contact *DenTron Radio Co., Inc., 1605 Commerce Drive, Stow OH 44224; (216)-688-4973.* Reader Service number 482.



The Galion linear amplifier from DenTron.

TERMINALL communications terminal from Macrotronics.



Compensating dipole antenna from Snyder.

COMPENSATING DIPOLE

Snyder Antenna Corporation now offers self-compensating dipoles that offer all the advantages of a conventional dipole plus increased efficiency. These full-band antennas have no resistors or capacitors and can be used with 50- or 70-Ohm feedlines. Available in 40-meter, 75/80-meter, and 160-meter models, prices start at $109.95. For more information, contact *Snyder Antenna Corporation, 250 East 17th St., Costa Mesa CA 92627; (714)-760-8882.* Reader Service number 485.

COMMUNICATIONS TERMINAL

Macrotronics, Inc., has introduced TERMINALL, an integrated hardware and software system which converts the Apple II or Apple II Plus into a state-of-the-art communications terminal.

TERMINALL includes all the necessary computer-interfacing, audio-demodulating, AFSK tone-generating and transmitter-keying hardware integrated in one cabinet. This reduces equipment interconnection to a minimum and allows the operator to be on the air receiving and transmitting Morse or RTTY or ASCII in minutes. Plug it into the receiver headphone jack and copy Morse code, Baudot, or ASCII. Plug it into the CW key jack and send Morse code. Attach a microphone connector and send Baudot or ASCII using audio tones (AFSK).

TERMINALL T2 requires an Apple II or Apple II Plus, 48K RAM, and disk drive. Software provided on disk in DOS 3.2 format (MUFFIN to 3.3). Latched and buffered cable plugs into any card slot (1 through 7).

TERMINALL comes complete with software on disk, assembled and tested hardware, and an extensive instruction manual. List price is $499. For complete information, contact *Macrotronics, Inc., 1125 N. Golden State Blvd., Turlock CA 95380; (209)-667-2888.* Reader Service number 484.

6-METER MULTIMODE

The IC-505 is a fully-synthesized multimode transceiver covering 50 to 54 MHz on FM (option), USB, LSB, and CW. Utilizing an internal battery pack (9 C-size batteries), the IC-505 puts out 3 Watts of rf power when run on its batteries, or 10 Watts when connected to an external 13.6-volt dc source; low power is 0.5 Watts.

IC-505 features include an LCD frequency display for low battery consumption, provision for internal memory backup, dual vfo's, 5 memories plus a call channel, memory scan, program scan, sideband squelch, LCD annunciators for vfo, scan,

IC-505 transceiver from Icom.

memory channel, call and split, and split frequency operation. The transceiver has a list price of $449.

For more information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

SOLAR MODULE

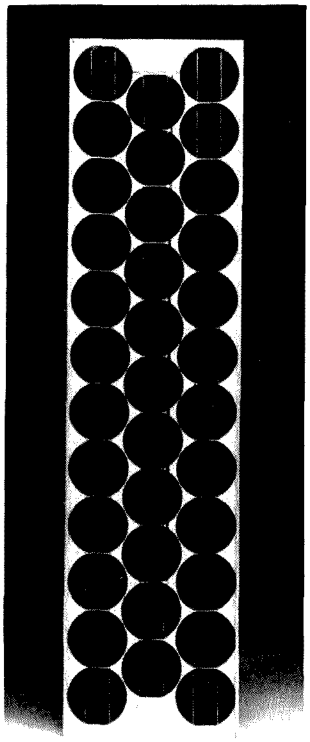
A photovoltaic module that produces 40 Watts of peak power using 35 solar cells is available from ARCO Solar, Inc.

The M51 module is designed for high voltage applications where efficiency and reliability are critical considerations. It maximizes Watt-hours per day while keeping balance of system costs down. It has been successfully tested beyond industry standards.

The new 1'×4' module is 10.75% efficient. Using single crystal silicon cells, it can even charge batteries at five to ten percent of noontime sun. Under such low light level conditions, ARCO Solar analyses show the M51 can deliver up to 25 percent more energy than a typical module of polycrystalline design.

Solar cells in the M51 are 100 percent electrically matched to ensure maximum power output. Each series-connected cell employs 44 contacts for enhanced reliability.

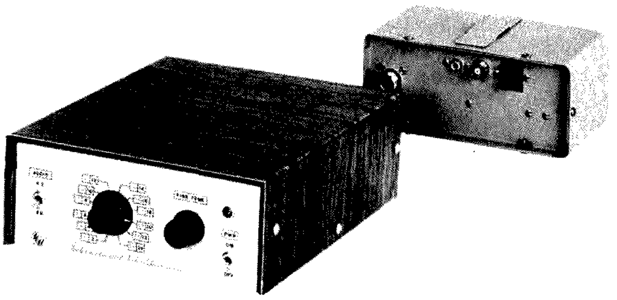
For more information, contact *ARCO Solar, Inc., 20554 Plummer Street, Chatsworth CA 91311; (213)-700-7458.* Reader Service number 481.



ARCO Solar's M51 module.

SATELLITE RECEIVER

The unique two-piece design of the International Crystal ICM TV-4400 satellite receiver permits mounting the downconverter at the LNA. Signal is fed to the baseband unit via RG-59 coax at 70 MHz. The dual-conversion receiver features step-switch tuning with variable fine-tuning control. A subcarrier output may be used with audio accessories. There are two standard audio outputs and a built-in dc block for LNA power. The ICM TV-4400 has a list price of $1295 and is available from *International Crystal Mfg. Co., Inc., 10 North Lee, Oklahoma City OK 73102.* Reader Service number 478.



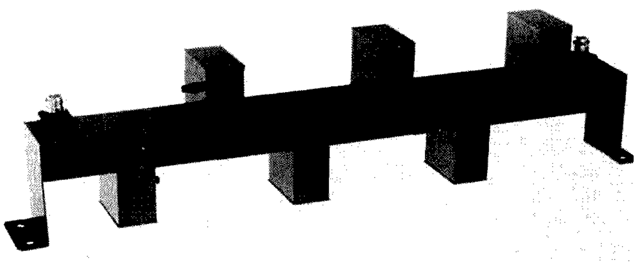
TV-4400 satellite receiver from International Crystal.

INTERFERENCE TRAP

The Model 3966 is a microwave trap for preventing strong microwave carriers from reaching Earth station downconverters.

The trap can block out up to 6 microwave telephone carriers (offset 10 MHz from transponder frequencies). Connectors are type N and the trap passes dc power to the LNA.

The trap is custom-made to customer's specific microwave offenders. Price is $180.00 for a single carrier trap plus $90.00 per additional interfering carrier. Delivery is 10 days. For more information, contact Emily Bostick, *Microwave Filter Co., Inc., 6743 Kinne Street, East Syracuse NY 10357; 1-(800)-448-1666.* Reader Service number 483.



Earth station interference trap from Microwave Filter Co.

1:1 BALUN

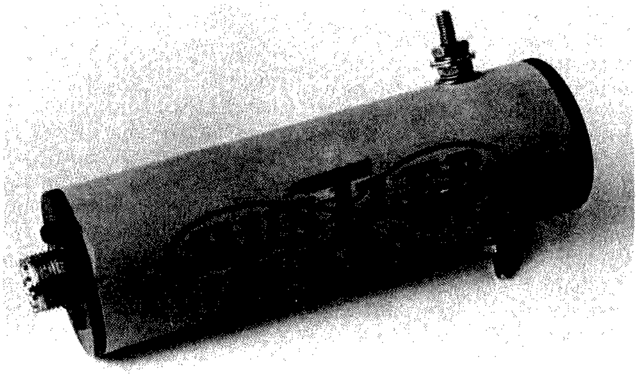
Hustler, Inc., now offers a 1:1 ratio balun to complement their line of HF amateur antennas.

The balun, designated model "BLN," features a low-loss air-core design eliminating saturation at high power levels while maintaining a uniform power balance in the system.

BLN features include a 1-kW input rating and bandwidth of 7 to 35 MHz with under 2:1 vswr.

All stainless-steel hardware and flying leads are supplied for connection to the driven element of beams, quads, or dipoles and coax termination into an SO-239 connector. The BLN is priced at $21.95.

For additional information, contact *Hustler, Inc., Sales Department, 3275 North B Avenue, Kissimmee FL 32741.*



1:1 BLN balun from Hustler.

NOVICE COURSE

A complete Novice course is available from VHF Communications. The course features six hours of theory sent by Morse code. The copy is then given in voice so that the student may check his or her progress. The package includes a copy of the Ameco *Novice Guide*. The introductory price is $21.95. For more information, contact *VHF Communications, 915 North Main St., Jamestown NY 14701.* Reader Service number 479.

APPLE SSTV

The COMMSOFT PhotoCaster™ provides an easy way for hams who own Apple computers to get started on SSTV with a full-featured black-and-white and color system. PhotoCaster includes a circuit board to interface an APPLE to a TV camera and a receiver/trans-

mitter, plus a two-disk software package which incorporates many advanced features.

In addition to transmitting and receiving pictures, PhotoCaster has provisions for adding titles and graphics, creating video special effects, enhancing images, retrieving and storing pictures on disk, printing high-resolution pictures with an MX-80 printer, and much more.

Black-and-white pictures are processed with a resolution of 128 by 128 pixels and 16 levels of gray. Shades of gray are presented on a standard CRT monitor by using dot dithering. In the color mode, 8 colors are available with 16 saturation levels. Color pictures are taken with an unmodified black-and-white TV camera using a three-frame RGB sequence. Standard RGB transmission formats are available in addition to a unique Apple-to-Apple single frame color mode which takes 8 instead of the usual 24 (or more) seconds to transmit a color picture.

PhotoCaster requires an Apple II or Apple II Plus computer with 48K of RAM and one disk drive. The price of PhotoCaster is $499.95 for the basic system which includes an assembled and tested circuit board and software. A complete system consisting of a Panasonic WV1400 camera, board, and software is available for $749.95.

FCC SAYS MORE 20-METER SSB FREQUENCIES

Expand the 20-meter phone subband? The FCC is considering just this action. Add good sunspots and you have DXer heaven! But what will FCC Docket 82-83 *really* do for DX?

The DXers, nets, and DX presently in the 14200-14250 range immediately will move down to fill the new subband. These operators want to be near the DX portion of the band and will move accordingly. In weeks—if not days—the new frequencies will be every bit as crowded as the bottom end of the 20-meter phone band is today. With any luck, however, the SSTV crowd will stay put on 14230, which will finally get them out of the DX area!

The hams who will benefit the most from the expansion will be the General class amateurs. They stand to gain the greatest percentage increase in frequencies and (depending on the final FCC decision) they might also gain access to that prized bottom 50 kHz! Wouldn't that be a switch! They would go from the status of a poor relation in the 20-meter DX world to head-to-head battles with top DXer W6AM. More likely, the FCC will settle for contiguous subbands and the Generals will gain 14225-75. The 66% increase will propel many a DXer into the ranks of DXCC.

Are there any losers in this proposed expansion? What about the DX hams who use 14150-14200 now? The top half of that range contains many of the DXers, DX nets, and long-haul communications. These hams will share with those stateside or move down, depending on interference to their operation. Below this DX layer lurk the personal, non-DX QSOs: long-standing skeds, families and friends, non-English QSOs. They will be the real losers. The RTTY just below 14100 acts as a floor to phone operators; voice communication below 14100 is almost unknown. Those amateurs who view amateur radio as a communications tool—and not as a pursuit in itself—are the amateurs who will be squeezed from the top as the DXers descend.

Will these hams jump below the RTTY, down to 14050-80? That is the present home of the CW rag-chewer, traffic nets, and domestic communications. You won't find many sharp CW filters here and SSB interference will hurt. Further down, the bottom of the band roars with the CW DX crowd, with kilowatts and filters. They will survive any pressure from above.

So DXers will be the prime beneficiaries of the new frequencies.

What about the other HF bands? In the same docket, the FCC wants amateur opinion on expanding other phone subbands, 80-10 meters. How might these changes affect DX?

Ten meters doesn't need any more phone frequencies; we seldom fill what we have at the peak of the sunspot cycle. Fifteen meters, on the other hand, cries out for phone expansion almost as much as 20. A hundred additional kHz, relocating the Novices to 21050-21150, would attract a lot of the 20-meter operators except at the bottom of the sunspots.

Any 40-meter expansion would force the Novices to move down to 7050-7100, still head-to-head with the VEs, but at least away from the shortwave broadcast stations. This move might be a welcome change! But there is no DX outside the western hemisphere above 7100, so phone expansion would be meaningless to the DXer. Now, if they could only get the foreign broadcast stations to go someplace else (I can think of a certain, overly-warm location), 40 meters could be a great band. But phone expansion? No, thank you.

An additional 25 kHz on 75 meters wouldn't revolutionize DX on the band, but it might go a long way in that direction. 75-meter DX is the exclusive province of the Extra. If other license classes get privileges below 3800, a whole new world of 75-meter DX might open up.

But don't rush onto the proposed 20-meter frequencies just yet. The FCC moves slower than New Hampshire molasses in January, and it will be a while before we can begin moving down. To help our DX totals meanwhile, we might keep an ear out for Erik SM0AGD, from somewhere in the South Pacific.

ERIK SJOLUND SM0AGD: DXPEDITIONER EXTRAORDINAIRE

Erik Sjolund left this spring for an extended DXpedition through the South Pacific, as one of the four-man crew of the 50' yacht *Marathon AQ*. Erik was lured from "retirement" from DXpeditioning by the fact that the skipper of the ship is a descendant of Leif Ericson. The support of the Sundsvall DX group and the Northern California DX Foundation help make the trip possible. The trip's itinerary reads like an atlas of the area (and a ham's dream-come-true): North Cook Islands ZK1, Tokelau ZM7, Central Kiribati T31, American Phoenix KH1, East Kiribati T3, Tuvalu T2, and more. The 1983 itinerary is even more ambitious and includes Spratly 1S! The last group to operate from Spratly had to dodge bullets (more about Spratly in a future column).

What kind of amateur would head off on a scheduled two-year voyage, which includes actively disputed territories, just to hand out radio contacts to the deserving few? Erik Sjolund SM0AGD is a very special amateur and a special person who has operated from more than his share of rare and difficult locations.

Erik began his DXpeditioning career about 11 years ago, when he traveled to Rhodes SV0 for a vacation. Although he had been an active amateur for about 20 years prior, this was the first time Erik operated from outside his native Sweden. The DXpedition bug bit, and bit hard.

Erik traveled extensively through his job with the European Space Agency, and he carried a radio everywhere he went: Easter Island CE0A, the Falklands (or is it the Malvinas?) VP8, and others. Erik then began traveling for the Swedish government to various embassies all over the world.

The well-known neutrality of the Swedish government helped open many doors for Erik. Swedish embassies in such out-of-the-way places as Bangladesh or Botswana were perfect locations for radio operations, and Erik's diplomatic connections paved the way for licensing. Erik also operated from Lesotho 7P8, Guinea-Bissau CR3, Laos XW8, Iraq YI, Turkey TA, and many more. Quite an impressive list! Finally, Erik "retired" and re-

turned to his home and wife, only to head off again this spring.

On his way to the South Pacific, Erik stopped by the International DX Convention in Visalia CA. While there he shared some of his experiences, including his recent trip to J5, Guinea-Bissau, with the hundreds of CA amateurs and guests.

THE SUNDSVALL DXPEDITION TO GUINEA-BISSAU J5AD

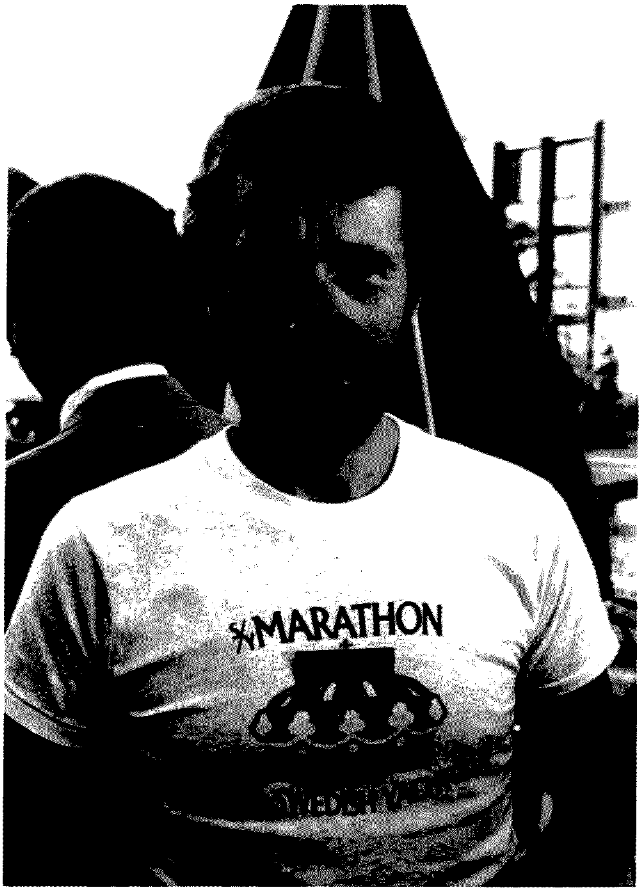
Erik had always wanted to reward his hard-working and dedicated QSL manager, Jorgen Svensson SM3CXS, with a fully-conducted DXpedition. His chance came in 1981, when Erik unexpectedly received permission to operate from Guinea-Bissau J5. Although greatly troubled by a bad knee, Erik immediately begain preparing for the trip: food, hotel, transportation, equipment, customs, antennas. A seasoned DXpeditioner, Erik completely constructed and fully tested each antenna before leaving Sweden.

The travel arrangements centered on Gambia C5, a popular tourist spot for Scandinavians on the west coast of Africa. Erik, Jorgen, and other members of the Sundsvall DX Group arranged to fly a small plane the 300 km from Gambia to the tiny capital of Bissau. To see the countryside, they would chance driving back—a decision which would almost prove their undoing!

Use of the small plane severely restricted the amount of weight the group could carry, and radio gear consumed most of that. Erik had purchased enough food for the entire two-week trip, but there simply was too much weight. So the group sat down to eat the two weeks worth of food before they left two days later!

Erik maneuvered the group's gear, including 2 Icom transceivers, 2 amps, and a couple of vertical antennas, through Gambia customs and rendezvoused with their pilot, C5ADX. A sandstorm in Guinea-Bissau delayed departure for a day, but the group finally arrived and was met by J5HTL, who helped secure licenses and provided other local assistance.

Their troubles were not over, however. Minutes after firing up the radios and getting on the air for the first time, bang! The room went dark. No power. Out-



Erik Sjolund SM0AGD on his way to an extended DXpedition to the South Pacific.

side, the entire town of Bissau was dark. "Maybe we shouldn't have used the amplifier," Erik mumbled, looking out over the dark city of 110,000 people.

The lack of power turned out to be a regular occurrence. Whenever the enormous football (we call it soccer) stadium turned on its lights, the entire city was blacked out. Fortunately (that's experience and foresight), Erik's radios could operate on car batteries, without the amplifiers. A portable generator powered the amplifier when the group was away from the hotel.

Despite the hardships of inconstant power and stomach problems from trying to eat two weeks' worth of food in two days, J5AD managed 20,400 QSOs in 9 days. Contacts were about evenly split between SSB and CW.

Now came the drive back to Gambia, 300 km north. "10 hours," the driver promised. That's about 20 mph on the tortuous dirt roads. The driver appeared with his battered "taxi," but the trunk was completely filled with a barrel of oil. The driver claimed he needed that much oil for the trip, and there wouldn't be any gas stations along the way. More likely, he was afraid someone would steal his precious barrel of oil if he left it behind for a day. He was probably right.

Erik finally convinced the driver to unload the oil and load their gear, and the car began to lurch toward Gambia. But Gambia is a small country completely surrounded by Senegal, and one must pass through Senegal on the way to Gambia. The trouble began at the Senegal border.

Dead tired from the trip and still bothered by his bad knee, Erik refused to pay the implied bribe for passage through Senegal. The border guards retaliated with a three-hour lunch, leaving the Sundsvall DX Group sweltering in the tropical sun. Finally, the two sides reached a compromise and Erik's party headed north. But now the border guard insisted on accompanying the travelers and claimed the front seat. It was a long ride to Banjul, Gambia.

Erik Sjolund and friends survived the trip, however, and pleased thousands of amateurs in the process. And now the modern-day Leif Ericson is off again, this time with transceiver in hand, and SM0AGD portable wherever is on the air again.

QSL Erik's operation via SM3CXS, as usual. Please include a separate envelope for each different callsign, since the cards will be handled in more than one location.

You can recognize Erik by his clean, crisp operating style and his courtesy. Erik also works an even balance between phone and CW. In honor of Erik, and to compensate for the remarks above about the expansion of the phone bands, let's look at a CW topic: zero-beating.

ZERO-BEATING FOR DX FUN AND PROFIT

Zero-beating is the process of aligning the transmitting frequency to that of another station. While important in SSB operation, zero-beating is crucial to successful CW DXing.

The best way to work a DX station in a CW pileup is to transmit on exactly the same frequency as the last successful station. This implies the ability to align the transmitting frequency to that of another station. How do you accomplish this?

The DXer can zero-beat separate receivers and transmitters by means of the spot switch: Tune in the desired frequency on the receiver, press the spot button, and adjust the vfo for an identical note in the receiver. The transmitter is now on the same frequency as the receiver.

But most of us have transceivers without separate external vfo's. No spot switch. Now what?

Again, tune in the desired frequency on the rig. Most transceivers employ an 800-Hz offset for CW. This means that when the dial is aligned on 14030, for example, the CW receiving beat oscillator in the rig (which generates the audible tone in the product detector) oscillates 800 Hz away from the frequency of the transmitting oscillator. If the audible tone is 800 Hz, the transmit and receive frequencies are identical.

But I prefer to copy CW at a lower frequency than 800 Hz. If I adjust my receiver to my preferred note of 650-700 Hz, my transmit frequency will move up 100-150 Hz above that of the other station. That station will shift up in frequency to match my transmitted frequency.

I then shift up still further when the DX station comes back, and we dance up the band. More likely, we will lose contact or never meet in the first place.

We can avoid this problem in either of two ways. First, we can learn to recognize and listen to the 800-Hz note which the rig manufacturers have selected. Or we can adjust the RIT or clarifier to compensate for our personal preferences. I prefer the latter approach.

Tune in a strong, steady carrier, such as WWV. In the CW position, tune across the carrier until the note drops in tone until it disappears. Now move up exactly 800 Hz. Your transmitted frequency should be exactly on the carrier. Adjust your RIT for your preferred note and mark the position of the pointer.

Now, to zero-beat the DX station, tune the rig for your favorite beat note and you will be very close to the correct frequency!

NOTES FROM HERE AND THERE

The French amateur radio society suggests watching for 3A2ARM, the official club station of Monaco, which is often on 14 and 21 MHz Saturdays, 0900-1100Z.

Heard Island plans move ahead, with the support of the Wireless Institute of Australia. An extended stay on Heard is scheduled for early '83.

REVIEW

THE HEIL EQ-200 MICROPHONE EQUALIZER

If you actively seek to improve your transmitter's audio, sooner or later you'll discover the concept of equalization (hereafter referred to as EQ). Simply put, EQ is the boosting or cutting of specific frequencies (or bands of frequencies) within the audio spectrum. In public address systems, EQ is used to flatten out the frequency response of the system, allowing maximum gain at all frequencies before feedback. In the recording studio, engineers apply EQ to sweeten sound and make it more pleasing to the ear.

Obviously, in amateur radio we needn't concern ourselves with either audio feedback or sweetening our sound. So why worry about equalization? Because many years ago researchers discovered that boosting certain bands of frequencies improved intelligibility. A slight boost, say, in the upper-mid-range area, makes our voices easier to understand. Because of this, microphone and transmitter manufacturers have been building such a boost into their equipment for years. More than anything else, this accounts for the subjective differences we detect between the qualities of various microphones and rigs. And it is precisely where we begin to run into some interesting compatibility problems. There is no agreement between manufacturers as to how much boost is necessary or at what frequency it should take place. Worse, some feel that the equalization should be done at the microphone, while others argue that it should be done at the rig. You can imagine the problems this presents! If both the microphone and the rig you buy have substantial boosts at the same frequencies, your audio is likely to sound "honky" and unpleasant. And if a manufacturer designed his rig with the characteristics of a particular microphone in mind, results will be unpredictable with another mike. The combination may lack highs, lows, or anything in between. Or it might have too much of something!

Which brings us to the Heil

EQUALIZING THE MOBILE SIGNAL

When a commercial sound contractor writes the specifications for a sound system to be installed in a large auditorium, he must know the room's resonant frequency. The dominance of this frequency can cause feedback, resulting in a less than optimal gain value for the sound system. By adding an active equalizer that notches out the room's dominant frequency, the likelihood of feedback is reduced, allowing more gain to be used.

The very same sound analysis procedure was applied to the internal cavity of four automobiles. The results were astonishing! From a Honda Civic to a GMC van, they exhibited a large rise in the 400- to 700-Hz range, the exact same place that mobile signals have a large peak in their audio.

If you think about it, you will probably realize that all mobile signals sound alike. It makes no difference what kind of microphone or transmitter is being used. These signals are characterized by low frequency rumble and vey little high-end audio response, and in most cases are very hard to copy when they are immersed in noise.

The fact is that the frequency of the car's internal cavity is reproduced through the mobile microphone and causes all of the signals to include a rumble. The hand-held microphones favored by most mobile operators only make matters worse; they have very little high-end response, with their −3-dB "hinge point" often lying as low as 1800 Hz.

Results from a typical on-the-air mobile setup are shown in Fig. 1. A Kenwood TS-120 transceiver with MC-30S microphone was installed in a GMC van. The signal was received on a Kenwood TS-820S and analyzed with a Heil AA-1 audio analyzer. Before equalization, a pronounced peak was found at 500 Hz, verifying the resonance check. By using a two-band equalizer between the microphone and rig, the resonant frequency of the passenger compartment was notched out, giving the audio a flat response. Next, boost was added to the high end, making up for the deficiency of the microphone. Receiving stations and the audio analyzer back in the lab all reported a 6- to 10-dB difference and there was a marked improvement in the intelligibility of the speech.

We found that articulation is the key factor in understanding a mobile signal. The all-important articulation is lost when the low frequencies predominate. In the worst case, these lows can overdrive the microphone preamplifier, leading to terrible distortion. The application of proper equalization to the audio section of an SSB transmitter will provide this necessary articulation without distortion.

Bob Heil K9EID
Marissa IL

The Heil EQ-200 microphone equalizer. (Photo by KA1LR/4)

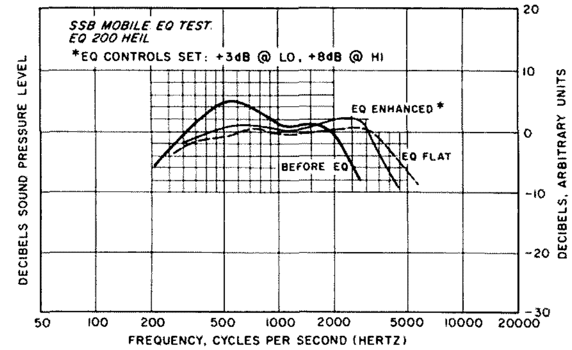


Fig. 1. SSB mobile EQ test results for the Heil EQ-200.

microphone equalizer. The idea is to connect the equalizer between microphone and rig. The LO and HI controls allow you to cut or boost the two bands of frequencies, correcting any deficiencies and hopefully improving intelligibility. A third control permits you to match the output level to what your rig wants to see. Does it work? Well, yes and no. If you just need to perk up your audio a little bit, dialing in a little LO or HI boost can improve things. But it's important to remember that changes you make will only be audible to someone listening to your signal. If you are dumb enough to adjust your rig on the basis of what someone you may or may not know is telling you over the air, you deserve what you get! You really need a means of listening to your own signal while you make adjustments. You're in good shape if you have one of the few transceivers with a monitor circuit. Turn it on, plop on a pair of headphones, and you'll get a pretty good idea of what you sound like to the rest of the world. If you have a second receiver, you are even better off.

One problem we noted in our installation is that the gain control had to be run at a fairly high level. The EQ-200 uses a pair of 741 op amps to do its work, and the noise performance of these devices is less than exciting—i.e., you hear some hiss. While this may or may not be noticeable in other installations, I recommend that Heil use a slightly better op amp in the future. After all, if someone is picky enough to want to EQ their mike line, they aren't going to want to add hiss to their signal!

The second problem I see is the placement of the controls on the front panel. Once you have gone to all the trouble to carefully set them, you don't want anybody messing them up. Internally mounted trimpots with three small access holes for a screwdriver would make the most sense to me.

Conclusions

Used correctly, the Heil EQ-200, which sells for $49.95, can improve the intelligibility of many microphone/transceiver combinations. Used incorrectly, it could make a good signal sound terrible. Please, if you don't have the knowledge or patience to adjust this or any other audio processing device correctly, don't buy it!

For more information, contact *Heil Sound, Marissa IL 62257*. Reader Service number 475.

Paul Grupp KA1LR
Casselberry FL

Editor's note: Heil Sound reports that a design change was made to the final amplifier stage of the EQ-200. By lowering the gain, they achieved a 20-dB reduction of the noise level leaving the unit. This should help in solving the problem, reviewer Grupp reports.

SILICON SYSTEMS DTMF DECODER

Anyone who has tried to tame a dual-tone frequency (DTMF) decoder using the ubiquitous 567 IC has probably thought that touchtone™ control probably isn't worth the hassle. The 567 decoder, although versatile, is far from ideal for decoding DTMF signals that have a variety of levels of distortion and volume. The 567 can give false outputs if input levels aren't carefully controlled, and frequency stability is only as good as the timing network. In short, getting a 567-based decoder working reliably at a remote repeater site is a lot like searching for an honest man—you're always disappointed in the end.

But take heart. Time and technology have passed the 567 by, and thanks to the development of switched-capacitor filters, we now have DTMF decoders in a single package which offer more features and better reliability than a handful of 567s. Silicon Systems, Inc., the people who first made commercial use of switched-capacitor technology, have a chip representative of this new breed in their SSI-201, a 22-pin IC which requires only four external components to operate as a complete DTMF decoder.

The SSI-201 uses 40 poles of switched-capacitor filtering to detect the presence of valid DTMF tones at the input. The filter center frequencies and bandwidths are controlled by a 3.58-MHz crystal (one of the outboard components), so frequency drift and temperature instability are a thing of the past. A valid tone can be detected in as little as 20 milliseconds and the audio input can be anything from 53 mV to 1.3 V. A 60-Hz notch filter on the chip reduces susceptibility to overload from hum.

Implementing the SSI-201 is very easy. Power required is 12 volts at about 30 mA. When valid tones are present at the input, the four output lines present either a hexadecimal (similar to BCD) or binary-coded 2-of-8 output, selectable by tying one pin high or low respectively. The outputs may be configured for either standard CMOS or tristate (high impedance) use. Another control pin allows detection of the full 16-digit set or the more standard 12-digit set. A strobe output is available to ease interface with clocked-logic systems.

A minor flaw with the SSI-201 is that the problem of temperature immunity has not been completely solved. The chip is specified to operate only down to 0° C (32° F), so you'll have to provide some sort of heat at your outdoor repeater site. The answer could be as simple as letting some current flow through a couple of resistors mounted near the chip.

This chip isn't cheap—$60 in single units (if you buy 10 or more, the price drops to $40.64). I buffered all its connections with the real world. I used a 741 op amp as an audio buffer, bypassed the power bus, used a series diode to protect against reverse polarity, and used a 4049 inverter package to buffer the digital outputs. All this may not be necessary, but I feel a lot safer knowing that there's an op amp between the phone line and my expensive chip.

When all things are considered, using a chip like the SSI-201 is well worth the additional cost. Now I *know* that my control system is reliable and that old Ernie with the weird voice won't bring up the autopatch every time he says, "Well, fine business, old man."

John Ackermann AG9V
Green Bay WI

ASTRON RS-7A POWER SUPPLY

The RS-7A is one of a series of 13.8-V-dc supplies with ratings ranging from 4 to 35 Amps. The 7A is good for 5 Amps continuous or 7 Amps at 50% duty cycle. I paid $64.95 for mine.

Ripple is spec'd at 5 mV peak-to-peak, full load and minimum line voltage. Load regulation is 50 mV. This is what would be expected from an industrial power supply, but it's much better than many of the supplies built for amateur service. A look at the schematic and the construction explains the performance. The regulator is a 723 IC, a somewhat elderly but altogether respectable chip. Regulator sensing is done at the output terminals, and the sense leads are twisted to minimize magnetic pickup from the transformer. The circuit includes not only foldback current limiting, but a crowbar circuit as well! Thus the unit resists damage very effectively, and if the regulator or the pass transistor should ever malfunction, the crowbar will blow the primary fuse and shut everything down in a millisecond or so. The pass transistor is mounted on a heat sink outside the back of the case, so ventilation is unnecessary. This keeps dirt out of the guts. That, in turn, means that the regulator is unlikely to become humidity-sensitive in its old age.

My unit has a varistor across the transformer primary, although the schematic doesn't show it. Nothing could be more convincing evidence of a thoroughly professional job of power-supply design. If the rig is expected to be available for operation in a disaster, it's extremely important to protect the circuitry against lightning damage. Several pieces of gear in my shack failed during a lightning storm a couple of years ago. After I put varistors across power and telephone line connections, there was no more trouble in subsequent storms. If there are any early-production units out there without varistors (or any other kind of station supply, for that matter), I recommend putting a GE V150LA20B across the primary.

The packaging is what's required, and no more. It's a simple modified steel minibox-style case, with the lid held on with sheet metal screws. Nothing is mounted on the cover; the unit is structurally complete when opened up for service. The line cord is solidly anchored.

The parts are good quality. The main capacitor looks to be either industrial grade or computer grade. I didn't recognize the part number, but it sure isn't any fugitive from a TV set. The

transformer was obviously custom-designed for the job, a requirement when a linear-regulator supply has to operate efficiently over the 105-125-V range.

On-the-air tests... I hooked it up to my UV-3 and dialed up a couple of repeaters I could hit full quieting. The signal reports said there was no audible hum. Key-down operation for 30 seconds caused barely noticeable warming up of the heat sink. Not having access to a power supply test set these days, I didn't carry the testing beyond that. From looking at the size of the heat sink, I'd have some doubts about running at 5 Amps continuously at the maximum rated line voltage, but if that became necessary it would be no trick at all to put on a heat sink about four times as big.

To summarize: Whoever designed this thing has an understanding of what a ham station indoor power supply has to do and knows how to design power supplies. This is probably the most cost-effective supply possible, and it leaves nothing to be desired technically. It's the kind you turn on and just forget about.

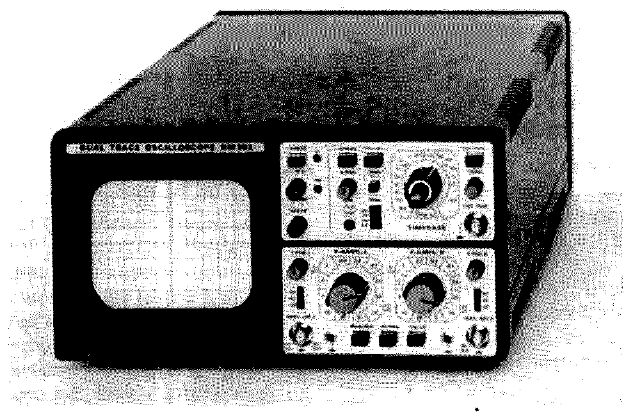
HAMEG HM203 OSCILLOSCOPE

The Hameg HM203 oscilloscope is much like ham radio: both are international phenomena. The HM203, a newcomer to the US market, features a rugged yet precise feel that one would expect of a piece of gear designed and originally manufactured in West Germany. The outstanding performance/price ratio reminds you of similar gear from the Far East. And not to be neglected is the fact that the HM203 is manufactured and serviced right here in the United States.

Oscilloscopes can be incredibly useful test instruments. Unfortunately, many hams are only familiar with the expensive laboratory-grade units found at work and school or the inexpensive surplus or used models that sell for a song at any swapfest. Hameg has managed to come up with an excellent compromise. Now you can have a dual-trace scope that has a 20-MHz (−3-dB) or 30-MHz (−6-dB) bandwidth, 3% accuracy, and variable triggering for under $600.



Hameg's HM203 dual-trace oscilloscope.

Weighing just over 12 pounds and measuring approximately 6 inches high, 11 inches wide, and 15 inches deep, the HM203 is designed with field-service applications in mind. The unit's compact front panel also lends itself to fitting into a tightly-packed workbench. One half of the unit is devoted to the cathode ray tube, which measures 5 inches diagonally. The usable screen is an adequate 10 cm × 8 cm, and the dark red grid allows you to interpolate measurements to about 0.1 cm.

One feature common to all Hameg oscilloscopes is a subdivided control section. The upper half of the HM203 is devoted to the power switch, intensity, and focus control, plus all of the timebase or horizontal display functions.

The lower half consists of controls for the two Y or vertical channels. The back panel is void except for ac power connection (with removable line cord) and sockets for direct connection to the CRT's vertical and horizontal control plates.

Dual Trace Capability

Two identical vertical channels are available. Each has a 12-step frequency-compensated input attenuator giving scales from 5 mV/cm to 20 V/cm. The attenuator is followed by a diode-protected FET preamplifier that has a 40-MHz bandwidth. Conspicuous by its absence was any kind of continuously-variable vertical sensitivity control. The lack of this kind of control did not prove to be a serious problem, I just made do by adjusting the vertical position potentiometer.

The 1-megohm, 25-picofarad vertical inputs can be switched between ac, dc, and ground. For single-trace or "mono" applications, you can use either channel. For those jobs that require two signals to be displayed, just push in the mono-dual switch and you connect your second signal. Triggering can be done on either channel. (More on triggering later.)

The Alt/Chop switch is an important part of successful dual-trace operations. If the signals have a low frequency (less than 1 kHz), the display will tend to flicker if both traces are displayed Independently. By choosing the Chop mode, the scope switches back and forth between the traces at a 120-kHz rate, displaying both signals on the same sweep and eliminating the flicker.

Timebase

According to Hameg, the HM203 uses a new type of triggering circuit. There is no need for any sort of stability adjustment, since most of the processing is done by a voltage comparator chip whose TTL output drives the sweep generator directly. The result is trouble-free triggering, even with fast-changing, high-frequency, or low-amplitude signals.

The sweep can be triggered by either vertical channel, the line, or an external source. A choice can be made between a positive or negative trigger edge and the trigger level is adjustable. A time axis can be displayed even when no signal is present—just place the 203 in the Auto trigger mode. Service technicians may be interested in the TV trigger mode which operates off the line or frame frequency.

A non-swept or X-Y mode is available by pressing the Hor Ext switch. The X signal is provided via the Y channel I input. The bandwidth of the X amplifier is approximately 2 MHz, with any phase difference between the two axes becoming apparent above 50 MHz.

Looking Inside

In addition to the controls and inputs already mentioned, the HM203 has front-panel access to the TR (trace rotation) control, which allows you to compensate for variations in the earth's magnetic field that cause a misalignment of the trace. The back panel includes access to the power supply fuse and the ability to change between 110-, 125-, 220-, and 240-volt power sources.

Taking the HM203 apart is simple. You just remove two screws and slide the case off the chassis. Once it's apart, you'll discover a straightforward yet impressive layout. The vast majority of the 203's components reside on two circuit boards. This includes most of the controls which are connected to the front panel via mechanical links. With service in mind, Hameg has used sockets for most of the ICs and FETs. The cathode ray tube is surrounded by Mumetal screening, reducing the likelihood of stray magnetic fields causing a problem.

Accessories and Documentation

The HM203 is ready to use the day it arrives. Each one comes with two X1/X10 probes. The Hameg penchant for quality is seen here—the probes include a compensation adjustment and feature interchangeable tips. Although the 203 is good to almost 30 MHz, the probes supplied top out at around 10 MHz. For measurements in the higher range, you can try some of the other Hameg probes. The line of accessories includes test cables, a 50-Ohm terminator, and a simple component testing jig (to be reviewed in a future issue of *73*).

The HM203 manual thor-

oughly documents correction operation of the instrument and even includes a brief discussion of errors that can affect your measurements. Plenty of service information is given, with emphasis on diagnosing and correcting the problem without using expensive test gear. A complete set of schematics is included and they are large enough to be pored over by the armchair circuit-design crowd.

Conclusions

Six weeks of using an HM203 at home and at work have reinforced my first opinions about this scope. It works as billed. The drawbacks such as the absence of a continuously-variable vertical attenuator are offset by extras like a built-in calibration signal. I found that the HM203 fulfilled my needs, which vary from designing simple digital-electronics circuits to troubleshooting a flaky SSB modulator to monitoring the stability of the power in the *73* darkroom. (In the darkroom application, the HM203 was left turned on for almost three days and exhibited no signs of instability or drift!)

I would be the first to admit that the HM203 does not equal the performance you get from many laboratory-grade instruments. But how often do you need 100-MHz bandwidth and features such as trace highlighting? The HM203 is adequate for many service jobs and should fill the needs of almost any hobbyist. With a special amateur price of $529, it beats just about everything, including units that you build from a kit.

The HM203 is available from *Rivendell Associates, RFD 5, Warner Hill, Derry NH 03038.* Reader Service number 487.

MICRO CONTROL SPECIALTIES' VHF/UHF CONTINUOUS-DUTY POWER AMPLIFIER

Reliability is the name of the game when repeater hardware is concerned. The equipment must be of conservative design unless you enjoy unscheduled trips to the repeater site—trips which always seem to entail a 20-mile drive through the season's worst storm.

The power amplifier is a case in point. You can't simply graft an everyday, mobile-type amplifier onto a repeater system and expect it to provide trouble-free service. Such amplifiers are not designed for the long periods of continuous duty which are faced by most repeaters during some part of each day.

A better choice is an amplifier built from the ground up for repeater operation, such as the PA-75 power amplifier from Micro Control Specialties (MCS). This continuous-duty, 75-Watt amplifier is available in 144-, 220-, and 440-MHz versions. It provides full output with 10-15 Watts of drive. In the interest of reliability, each PA-75 is burned in for four (count 'em, four) days before being shipped.

Most VHF/UHF amplifier circuits are designed to operate from a 12-V dc power source. In contrast, the circuits in the PA-75 use 24 V dc, which is produced by a built-in 105-125-V ac supply. The 24-V design means that the amplifier runs more efficiently, and it allows the power supply to be made physically smaller. The amp *will* operate from an external 12-V dc source and automatically switches from the ac lines to the dc source in the event of an ac power failure. Output power is reduced to 50 Watts when the amp operates on 12 V dc. A pair of 2N5643 final transistors gives the PA-75 its punch. The amp features excellent output filtering, with harmonics suppressed at least 65 dB.

The enclosure of the PA-75 fits standard 19-inch equipment racks. The front panel is kept as simple as possible—just three fuse holders and a dc ammeter for measuring amplifier current. Cooling for the finals is provided by a large heat sink and a high-volume fan. The fan also cools the power supply.

In our 2-meter repeater installation, an amplifier was needed to improve the signal on the far side of a mountain ridge. Since we were already using the MCS Mark 3CR repeater with good success, it seemed only natural to give the matching PA-75 a tryout.

Installation could not have been easier. We simply placed the amp in-line after the exciter output and plugged it in. Voila! Our repeater was transformed from a 15-Watt into a 75-Watt machine.

The amateur net price for the PA-75 is $493 for the 2-meter version, $544 for 220 MHz and $595 for 440 MHz. A $50 discount is available if the amp is purchased at the same time as an MCS repeater.

In five months of operation, our PA-75 has been completely trouble-free. It has performed precisely as advertised and has enabled us to fill some annoying gaps in our coverage. The PA-75 is a rugged, reliable answer to the repeater amplifier question.

WORKED TRUMBULL COUNTY AWARDS

The Warren (Ohio) Amateur Association, Inc., announces its Worked Trumbull County (WTC), Worked Trumbull County Mobile (WTC-M), and Worked Trumbull County YL (WTC-YL) awards. These programs are designed to promote increased amateur radio activity among and with Trumbull County Amateur Radio Operators. The awards are also award operating achievements.

Application: Send applications and all correspondence to Don Lovett K8BXT, Awards Chairman, WARA, PO Box 809, Warren OH. One dollar must accompany applications from W, K, and VE amateurs; all others should send three IRCs with application. Only Trumbull County applicants must submit actual QSL cards. All others should have certification letters from two other radio amateurs who signify that they have seen and checked the applicant's QSLs. Each application must also be accompanied by a list of the calls worked, with full log data for each contact.

Requirements:

- WTC—For each certificate or endorsement, Trumbull County applicants must have 20 contacts with other Trumbull County amateurs. Other W, K, and VE stations must contact 10 Trumbull County amateurs, while DX applicants must have five contacts.
- WTC-M—For each certificate or endorsement, Trumbull County applicants must have 20 contacts with other Trumbull County amateurs operating mobile in Trumbull County. Other W, K, and VE stations must contact 10 Trumbull County amateurs operating mobile in Trumbull County, while DX applicants must have five contacts.
- WTC-YL—For each certificate or endorsement, W, K, and VE stations must contact 10 Trumbull County YL or XYL amateurs, while DX applicants must have three contacts.

Award: A certificate will be issued on each approved application but in order to appear on the certificate, special endorsements must be filed with the initial filing, each containing at least 25 percent new contacts. Initial endorsements are free of charge but endorsements made on later dates will take the form of WTC certificates. Applications for these must contain proper filing fees. Endorsements may be "All One Mode," "All One Band," "All Mobile-to-Mobile," or "All Members of the Warren Amateur Radio Association, Inc."

Net contacts, contacts made through repeaters, and contacts made before January 1, 1959, cannot be counted.

WORLDWIDE AWARDS DIRECTORY, VOL. I

If you like to go after awards or win contests, this directory is a must! Volume I lists over 270 awards from all over the world, with names and addresses, costs, and descriptions. $9.95 brings Volume 1 to your doorstep. Volume 2 is in production now and will cost $5.95 for an additional 130 awards. Why not order Volumes 1 and 2 for a combined price of $12.75? The

Worldwide Awards Directory is for the amateur radio operator who is interested in showing his proficiency to others at radio communications throughout the world. You will never know how easy it is unless you know how to go about it. You probably already have enough QSLs in your files for some of the awards. $9.95 includes all postage and handling. COD extra. Quantity discounts available.

Also, if you know of some awards that you would like listed, please let Larry know and they will appear In the next volume. Write to: Larry Kebel KBØZP, 736-39th Street, West Des Moines IA 50265.

HONG KONG AWARDS

HARTS meets every Tuesday at 1700 local, excluding public holidays, at the China Fleet Club, Arsenal Street, Wanchai, Hong Kong Island.

Nine Dragons Award

One contact with a country in each of the following 9 zones: 18, 19, and 24 to 30. Contact for zone 24 must be a VS6. Stations within the 9 zones require 2 contacts in each zone, with 2 VS6 contacts. Contacts after Jan. 1, 1979, only, are valid. Fees are US $3, Aust. $3, £1.50p. postal order, or 24 IRCs.

Firecracker Award

Six contacts with different VS6 stations. Stations in zones 18, 19, and 24 to 28 require 10 contacts with different VS6 stations. Contacts after January 1, 1964, only, are valid. Fees are US $2, Aust. $2, £1 postal order, or 10 IRCs.

Usual Conditions

Certified log extracts only—no QSL cards are required. Payment to be made in cash; no bank drafts. Postal orders to be left blank. Claims to: Awards Manager, HARTS, GPO Box 541, Hong Kong.

HAROAA AWARDS AND CERTIFICATES

These awards are of high quality and will make a very nice addition to any radio room. The awards are available to all licensed amateurs and amateur stations. Please do not send QSL cards. A list showing full details of the contacts (log information) should be certified by one other amateur or radio club officer. Photocopies of your QSL cards or original log will also be permitted. At your request, special endorsements will be added, such as: CW, SSB, all YL, QRP, RTTY, SSTV, one band, etc. If you so desire, you may request separate awards for each special endorsement. Contacts may be made over any period of years. Contacts made through repeaters cannot be used. Satellites permitted. Please pass this award information along to another amateur or post it at your local club. All correspondence or applications should be sent to: **HAROAA, PO Box 341, Hinckley OH 44233, Attn: Awards Manager Gary Zimmerman WB8RTR.**

Application for each award must be accompanied by three US dollars to cover handling and award costs. Payment may be made by cash, personal check, money order, ten IRCs, or first-class-rate US postage stamps. DX applicants may send a money order made out in US funds, ten IRCs, or any of the above.

If at any time your award is lost, misplaced, or damaged in any way, send the date, award number, and pertinent information, and we will replace it free of charge. All awards include the special HAROAA gold seal.

Great Lakes Award

This requires one contact with each state bordering the Great Lakes: New York, Pennsylvania, Ohio, Michigan, Indiana, Illinois, Wisconsin and Minnesota.

Super Certificate Hunter Award

This HAROAA award is designed for the serious certificate hunter. To earn this award, you must have a minimum of ten amateur radio operating awards. Simply list the awards that have been issued to you. Special endorsements are 10, 25, 50, 75, 100 plus.

HAROAA DX Award

This is obtained by working DX stations. It is the number of stations worked that is important. Each DX station counts as one, even if several are from the same country or area. Special endorsements for this award are 10, 25, 50, 75, 100, 200 and 500 DX contacts.

HAROAA Insomnia Award

This award is earned by communicating with one other amateur radio station for a minimum of one hour between the hours of 1:00 and 5:00 am. A super conversation piece for your shack.

HAROAA Super Operator Award

This certificate is rendered for those providing a service on behalf of amateur radio, such as weather observation, public service, emergency work, helping a new ham, providing communications for a community function, etc. The requirements are for the applicant to briefly describe the event or service. The officials of HAROAA will determine whether it deserves this special recognition.

HAROAA Official Traffic Handler Award

This award is a self-issued achievement, allowing you to display the fact that you are indeed an official handler of radio traffic.

ISLAND DX AWARD

The IDX Award, sponsored by the Whidbey Island DX Club, is probably one of the most sought after awards in the DX community. This award is available to licensed amateurs and shortwave listeners worldwide.

The IDX Award is issued for

ISLAND DX COUNTRY LISTING

The IDX Awards Program uses DXCC countries which are bona fide "islands" as recognized by the National Geographic Society. The first criterion is that they must have been DXCC countries on or after October 1, 1977, as stated on the DXCC List of the ARRL. Any "qualifying" DXCC country omitted from this list by error or which has been recognized for DXCC after the release of this listing will be added the next time it goes to press. In the meantime, applicants may count these new countries in their tally.

2 × SSB, 2 × CW, 2 × RTTY, 2 × SSTV, and mixed mode, as well as mixed- and single-band accomplishments. To meet the minimum qualifications, applicants must work fifty (50) IDX islands for the basic award. Endorsements are given in increments of 50 islands, up to and including the maximum number of islands possible.

All DXCC countries which are bonafide "islands" are the only qualifying contacts. A special IDX listing appears within this column. To be valid, all contacts must have been made after October 1, 1977.

To apply, prepare a list of qualifying contacts in prefix order. Please number your contacts 1 through 50, etc. Include the call of the station worked, IDX island name, band, mode, date, and GMT.

Do not send QSL cards! Have your list verified by two amateurs or local radio club officials. Confirmation of each contact must be in the applicant's possession at the time it is being verified.

Send your list of contacts along with $4 in US funds only and a 4- × 9-inch business-size self-addressed stamped envelope to the following address (foreign stations may substitute for the fee by enclosing an SASE and 20 IRCs): Whidbey Island DX Club, Attn: IDX Award, 2665 North Busby Road, Oak Harbor WA 98277.

Rules governing this award program are reviewed annually in the month of September. Please enclose an SASE with any enquiries regarding this award program.

ELMIRA NY

Elmira area amateurs will operate W2ZJ from Chemung County's 1st Annual Good Neighbor Festival 1300Z, July 31 through 2100Z, Aug. 1. Frequencies: 30 kHz up from the lower edge of the General-class phone band on 20, 40, and 80 meters. Special certificate for large SASE to: ARS W2ZJ, General Delivery, Elmira NY 14904.

MT. DAVIS PA

The Somerset County ARC will operate AK3J for the second annual DXpedition from the highest point in Pennsylvania, Mt. Davis, from 1800 UTC August 7th to 1800 UTC August 8th. Frequencies will be the first 25 kHz in the General section for phone and the Novice section for CW. A beautiful certificate will be sent upon receipt of QSL card and $1.00. QSL to Box 468, Somerset PA 15501.

SMYTH COUNTY VA

The amateur radio operators of Smyth County VA, in celebration of the county's sesquicentennial, will be on the air Aug. 21, 1982 from 0000Z until 2100Z. Frequencies will be 15, 40, and 80 meters, up 10 kHz from the bottom of the general phone band and Novice CW band (as activity dictates). The call used will be W4KON. Please QSL with a large SASE for an attractive certificate and booklet about the county to: Ken Sturgill KC4IH, PO Box 526, Marion VA 24354.

SOUTH BASS ISLAND OH

The Huron County Amateur Radio Club will celebrate the 169th anniversary of the Battle of Lake Erie by operating from Perry's Victory and International Peace Memorial on South Bass Island in Lake Erie. The station, WA8HUR, will be on the air beginning at 1000Z August 21, 1982, til 0000Z August 22, 1982. Operating on SSB, the frequencies will be: 3910, 7250, 14280, 21360 and 28550 kHz. The CW station will be found at 40 kHz up from the bottom of each HF band. A Novice station will be found at 3720 kHz and at 7115 kHz. An FM station will be operated on 146.52 MHz. A special QSL card will be issued to all those making contact who send their QSL and an SASE to ARS KF8O.

FLUSH KS

The Kansas State University Amateur Radio CLub, WØQQQ, Manhattan, Kansas, and the Manhattan Area Amateur Radio Society announce the first annual DXpedition to Flush, Kansas, in Pottawatomie County. It will be held on August 29, 1982, for 24 hours of continuous operation beginning at 0000Z.

CW operators can work WØQQQ around 21.112 MHz or 7.112 MHz, and phone operators will find WØQQQ around 14.292 MHz or 3.892 MHz, depending on band conditions.

Successful participants will receive a handsome 8" × 10" certificate by sending an SASE to WØQQQ, Electrical Engineering Dept., Kansas State University, Manhattan KS 66506.

Flush is a quaint metropolis in the beautiful Flint Hills region of Kansas, 12 miles east of Manhattan, home of Kansas State University.

MT. PLEASANT IA

The Mount Pleasant Amateur Radio Club will be operating a station at the Midwest Old Threshers Reunion in Mount Pleasant, Iowa, September 2-6, 1982. Using club call WØMME, they will be operating in the General portion of 80, 40, and 20 meters.

Amateurs from the Mount Pleasant area will also be handling emergency communications on the grounds and will be providing talk-in on 147.99/.39 (WØMME/R) and 146.52 simplex for those attending.

Several hundred amateurs are among the 250,000 people annually that attend this display of memorabilia from America's past. Such things as steam engines, vintage cars, trolley cars, antique radios, and threshing by horse and steam power will be on display.

Hams attending are invited to visit the ham shack and sign the guest book. Admission for the five day event is $4.00. Camping is available on the grounds. For further information, contact Dave Schneider WDØENR, 507 Vine, Mount Pleasant IA 52641.

PIQUA OH

The Piqua Amateur Radio Club (W8SWS/8) of Piqua, Ohio, will operate from the Colonel John Johnston Farmstead, an historical Indian museum, on September 4-6 from 1400 to 0000 UTC.

Colonel Johnston, a federal Indian agent, built his Dutch colonial farmhouse in 1808; it's the only Indian agent house in Ohio. This is Piqua Heritage Festival Days, the first celebration of its kind in the state. Piqua is celebrating its 175th birthday.

A special picture QSL card and 8½" × 11" certificate will be sent to all stations who QSL with a large SASE to Larry Underwood W8UO, 811 N. Sunset Dr., Piqua OH 45356.

Frequencies for W8SWS/8 will be SSB 3.900, 7.250, 14.290, 146.460, and 7.115 (1800-2000 UTC).

PALMYRA

The M.O.T.H.E.R.S. (Marengo Over-The-Hill Electric Radio Society), an informal group of radio amateurs in the north-central Illinois area, have been planning a DXpedition for some time. So far, the destination and duration of the expedition had only been speculation. Last month, however, the destination, Palmyra, was announced. This came after confirmation of a landing permit and operating permission had been received from local authorities. The fact that this Palmyra is located in south-central Wisconsin hasn't dampened the spirits of WB9NKH, K9UA, KF9E, KC9DC, or WA9TAH, the expected operators.

The DXpedition will attempt the landing, initial setup, and possibly some limited operation on September 11, 1982, with a full-blown multi-transmitter operation expected on September 12, 1982, from approximately 0700 to 2100 CDT. The operating frequencies will be up 30 kHz from the bottom of the CW band edges and the General phone band edges.

Since Wisconsin and Illinois have fully reciprocal licensing agreements, the DXpedition will use the call WA9TAH, with QSLs available for an SASE.

CORRECTIONS

The crystal X1 used in the British VHF converter project (April, 1982) is correctly listed as 38.667 MHz in the text and Parts List. The value shown on the schematic is incorrect.

Minor engineering changes made since the design was published include substituting BF274s for the BFW92s used for Q3 and Q4. C6 has been changed from 22 pF to 47 pF.

SATELLITES

SOVIET SURPRISE!

On May 17, World Telecommunications Day, the Soviet Union placed yet another amateur radio satellite into orbit. However, the unusual manner of its launch and the technical details so far released make it clear that this is no ordinary amateur bird.

The satellite, called ISKRA-2 ("iskra" is Russian for "spark"), was put into orbit by two Soviet cosmonauts who simply pushed the spacecraft out an airlock aboard the Salyut 7 orbiting space station. Several sources, including Radio Budapest, have said that ISKRA-2 carries a 15-to-10-meter communications transponder, which would be the first use of the 21-MHz band for an amateur communications satellite. Telemetry beacons from the new bird have been copied on the high end of 10 meters at 29.576 and 29.875 MHz, using the callsign RK02. At press time, no transponder activity had been heard.

ISKRA-2 is in a rather low orbit, less than 225 miles high. This means that the satellite will have a rather limited lifetime, unless it carries some means by which to raise its orbit.

The launch, which was shown on Soviet television, is apparently only the second of its kind. In 1972, the Apollo 16 astronauts placed a small satellite into orbit around the moon.

PHASE IIIB

It now appears that the long-awaited launch of the Phase IIIB satellite will take place next January and not this summer, as had been hoped. The delay comes as a result of problems with the government and scientific satellites which are the primary payloads for the European Space Agency's Ariane rocket.

Phase IIIB is now scheduled to fly aboard the seventh flight of Ariane, but until the problems with the other satellites are solved, no launches can take place. Meanwhile, the amateur Phase IIIB bird is ready to go.

Thanks to *AMSAT Satellite Report*.

THAT BIG TABLE

Our monthly table of amateur satellite data this month takes on a new form, designed to pack a lot more information into only a little more space. Joining the usual data for OSCAR 8 are reference orbit predictions for four of the Soviet Radio Sputniks, RS-5 through RS-8. Each of these five satellites carries at least one operating communications transponder or robot (automatic QSO device).

This table provides reference orbit data for each day of the month on the cover of this magazine, plus the first half of the following month. For each day during this period, two items of information are given for each of the five satellites. The first number (UTC) is the time (Universal Coordinated Time—same as GMT for most purposes) of the satellite's first northbound equatorial crossing of the day. The second number (EQX) is the longitude (degrees west) at which that crossing occurs. The data in the table is based on the Project OSCAR, Inc., orbital predictions.

Using these two numbers, there are a variety of ways to determine when any of the satellites will be within range of your location. If you have a microcomputer or programmable calculator at your disposal, you can make use of one of several programs published in *73* and other amateur publications. The new AMSAT Software Exchange has a good selection of satellite tracking programs. The OSCARLOCATER package from the ARRL gets the job done in a simple but effective manner. A completely manual method for making rough estimates of satellite accessibility was presented in the October, 1981, issue of *73*, page 178.

Addresses: AMSAT Software Exchange, Box 338, Ashmore IL 61912. ARRL, 225 Main Street, Newington CT 06111.—Jeff DeTray WB8BTH.

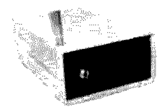
DON'T TIME OUT. . . . TIME IN



Model TI-10 time alert for repeater operators to avoid timing out repeater.
(Patented)
*Sensitive enough for H.T.S.
*Automatic; Senses RF carrier-no connections to rig
*Battery powered
*Resets on carrier drop-out
*Adjustable timing period
*Size 5 1/4 × 3 5/16 × 1 3/4
*Weight 8 oz./226.8 Grams
Piercing, 6.5 KHz alert tone

Model TI-10 assembled $69
Model TI-10k, kit form $57
Shipping and handling add $3
Printed Circuit Board and Documentation $20

Introducing Toggle Time

Toggle Time is a 10 minute timer that would be utilized by a ham to keep within FCC 10 min. ID rules. It is actuated by a toggle switch which serves two purposes:
1. Starts Timer
2. Turns on Power
Only one switch on box is all that is present. Price $14.95 includes battery.

When ordering, please specify model

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

hibit had a nice restaurant with no wait at all, right in the middle of the lunch hour.

Sherry and I went to the restaurant in the Chinese exhibit for dinner. Tom Salvetti, of Ten-Tec, was with us and we went right in with no wait at all. The food was real Chinese. It was good, but not outstanding. Sherry prefers to use chopsticks when eating Asian food and this was a bit of a problem. The waiter, a Chinese lad from the Knoxville area, explained that they only had three sets of chopsticks for the whole restaurant! He managed to get one of the sets for her, but the rest of us had to eat with forks.

The food prices are a bit above what I'd normally expect, but not astronomical. China seems to be getting all she can out of the fair (they *need* dollars, so that's not a surprise), with their dinners running around $14 per person. That's as bad as a banquet price. Belgian waffles were $2.10 instead of perhaps $1.50...and so on. High, but not prohibitive. They have to get their $110 million back some way, don't they?

In all, I would suggest that if you are going to be anywhere near the Knoxville area, you should allow a couple of days to see the fair. Never mind all the put-downs...it's a good show and the people couldn't be more friendly.

ROCHESTER

The debacle of '81 still hung heavy over the 1982 running of the Rochester Hamfest. It's still a shadow of former years, but perhaps with the relaxation of harassment by the tax people, the exhibitors and then the crowds will be back.

This year there was but *one* major manufacturer exhibiting: Hy-Gain/Telex. A few dealers were there, hoping that the New York tax people would not bring in the police and threaten again to close down the whole show. The dealers seemed to feel that business was okay, considering the economy.

There is a plan to move the banquet to Friday night and keep the show to one day on Saturday. This would allow hams to arrive the night before, attend the banquet, and then spend the day at the show. After a full day of browsing around the flea market, most hams are too tired to wait for the banquet; they just drive home to rest. It may be better to run it Friday night. It's worth a try.

After all of the fuss from *CQ* about attending hamfests, guess who was not there? Heh, heh! But then *Ham Radio* was also conspicuously absent. They seem to have pulled in their horns almost completely and become invisible. *73*'s Jim Gray was there to keep 'em honest...answer questions and fly the flag.

Speaking of the magazines, guess who was at the ARRL booth? There were a lot of rotten remarks about Harry being dead and refusing to lie down. I think that sort of thing is in poor taste. As I've written, I think the least the board could have done for Harry is to make him a president emeritus like they did the previous president. And if they have any real case against him for malfeasance, I think they should bring it out in the open, not just make sly hints about it. Harry should be given the credit he deserves for building up the League, for promoting satellite communications, and for his enthusiasm for packet communications, RTTY, and so on. Let's not have another of those crummy deals like they pulled on Don Miller.

Other than that, Rochester was upbeat this year, looking better. But Harold Smith was almost invisible again this year...where *are* you, Harold? He's the one who almost single-handedly organized and built up the hamfest over the years, turning it from a small independent effort into a genuine ARRL hamfest.

FCC NEWS

The FCC has extended the deadline for filing comments on Docket 82-83 to August 16. Reply comments are due September 16. Docket 82-83 proposes wider phone bands. For more information, see pages 143-145 of the May, 1982, issue of *73*.

The return time limit for Novice exams was extended to 60 days, effective May 6, 1982. This change will be of interest to volunteer examiners who previously had 30 days to return the test papers.

SADDLE STITCHING

In addition to the cover design change, we are also changing to what is called "saddle stitching" of the binding. The idea is to get back to the way we used to be when *73* was running a raft of small construction projects. We want to make the magazine easy to open up while you are working on a project. With the square binding, called "perfect binding," the magazine may look better, but it is a bitch to keep open on the workbench. I really hate it when the magazine flips closed while I'm wiring some chips together.

We're going to be concentrating on publishing as many relatively simple construction projects as we can scare up for you, so get your soldering iron out and start shopping for parts.

A NEW COVER...AGAIN?

Sure, why not? Every few years we get kind of fed up with everything being the same. We look around for ways to make *73* better...or worse, depending on your reactions to change.

The new cover solves some serious problems for us. First, it will stop the continuous flack we've been getting from *73* readers who liked the old contents type of covers. It *is* a lot easier to find things when the table of contents is right there on the cover, no question about that. And since virtually 100% of the *73* readers save their magazines religiously and use them for reference, this is a big plus.

Another problem was our desire to use color pictures brought back from DXpeditions on the cover. If you are not into photography, you may not know that 35mm color pictures can't be enlarged to the full cover size without getting fuzzy. Normally we would want to use a larger film format camera for cover shots...such as a 6 x 6 cm or a 6 x 7 cm such as the Hassleblad or Mamiya RB-67 cameras. These will enlarge and provide sharp cover pictures. Just look at some of the cover pictures on *QST* in recent months and you'll see what I mean...fuzzy.

By running the pictures in a smaller format on the cover, they will be nice and sharp... and look better. Also, we'll be able to run maybe two or three pictures instead of just one.

I realize that you probably are no more a fan of change than I am and will take a few months to get used to the new look. For all my insistence on change being important in amateur radio, I'm as much of a stick in the mud when it comes to change as you probably are. Let's try it and see how it plays.

HAM HELP

I need help on my code speed for the General ticket.

Howard Halperin WB7WDI
4122 West Flower St.
Phoenix AZ 85019

Wanted: Information on the Gonset Model 900A 2-meter Sidewinder. I would like to get in touch with anyone with parts for this unit or who can suggest where these parts can be found.

Peter Mitroff VE3DSW
8 Marsten Dr.
St. Catharines ONT L2N 3C7
Canada

I would like any information on the Globe Electronics HG 303, including manuals and schematics. I will purchase at a reasonable price or will make copies and send an extra set of copies back to you with the original.

Al Wilde W8JZZ
5580 E. Galbraith Rd.
Cincinnati OH 45238

I need a Johnson Viking Model 122 vfo to use with a Johnson Adventurer.

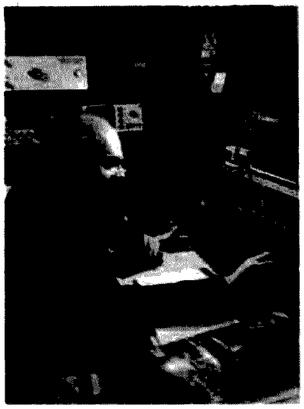
"Cheap Trick" TVRO Receiver—60

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



"Wayne, after having read your editorials for many years I feel I know you personally," said Rudolf Aumann HK1ESU the other day in Cartagena, Colombia. Rudolf, hearing that I was in town for a couple of days, came to my hotel to find me after failing to get through by phone. He found Sherry and me just finishing dinner in the garden of the Cartagena Hilton, where they had served an outdoor barbeque cookout.

I found Rudolf a delightful person with many interests, quite wrapped up in his second hobby of collecting pre-Columbian antiquities. Indeed, he has a collection which rivals those of museums. He found, as have many others, that the real Wayne Green, whoever that is, comes through in my editorials.

The Colombians are most friendly. Sherry and I, taking advantage of the Eastern Air system excursion fare, finished off a hectic business trip with a couple of days of relaxation in Cartagena. This gave us a chance to rest a bit and see a new country. It also added to my count of countries visited.

Of course, getting to Cartagena is an adventure in itself. Having arrived with no warning from either friends who had lived there or from the tourist guidebooks, I found myself knee-deep in the barracudas which inhabit many of the third-world airports. Providence was in my favor in that all of the car rental agencies were closed, it being Sunday afternoon. Sherry had tried to reserve a car for us, but fortunately she wasn't able. I'll explain.

The taxi drivers at airports ...and their pimps...start out asking about two to three times the normal fare. This is complicated by their knowing no English and me knowing little Spanish...or Swahili, or whatever the local language. Eager hands reach for your bags, fully expecting to net at least a buck or two for carrying them even the shortest distance. They assure you that all of the official money changers are closed, but they have a friend who will give you a very good rate...sixty pesos to the dollar.

After bargaining the taxi fare to the bus station down from \$15 to \$10 (\$5 turned out to be more like the going fare), we plopped into a taxi...a 1955 Chevy, I think...and were off to Baranquilla. Unless you've been to a poor country, you have no idea of what poverty can be. We really have nothing approaching it anywhere in the United States. Everything is in disrepair...the streets, the sidewalks (where there are any), the buildings, walls...all broken and falling apart.

Colombian buses are about the only means of transportation, so they are usually packed solid with people. Air conditioning of cars and buses is rare, so the windows (if any) are open. It's hot. Remember that the equator goes through Colombia, so it's hot all year around. There are few private cars in Colombia, so the need for buses is great, with the result that they are everywhere, each fighting to pass the others along the narrow streets. Most of them are gaily painted and decorated, reminding one perhaps of the "art" in the New York subways.

The bus depot turned out to be a street corner more than normally infested with buses. We found the place to buy tickets and splurged a big \$8.00 for two tickets to Cartagena. The bus was scheduled to leave at 2:30 pm, if we wanted a regular bus. If we waited until 6:30 pm we could take an air-conditioned bus! We really didn't want to stand on a street corner in Baranquilla with our hand luggage and two big suitcases for four hours, so we opted for the 2:30 trip. It wasn't bad at all.

Once out of the city, the bus rolled along the narrow road at around 60 mph, passing just about everything in sight. The countryside consisted of sparsely populated rolling hills, with few towns. We did stop occasionally to let the passengers buy food from roadside vendors...freshly cut pineapple slices, pineapple fritters, shashliks on a stick...things like that. At one point, two children got on the bus and went through a ten-minute recitation in exchange for a few coins, getting off at the next stop for a return on the next bus and another recitation.

As the bus threaded its way through the narrow streets of Baranquilla, none with any route markings that I could see, I was most thankful that the car rental agencies had been closed. Imagine trying to find my way through all *that*! Even once out of the country there were few signs at crossroads. Add to all that the seemingly fatalistic driving attitude of the truck and bus drivers and you can see why, even with the heat, I was glad to be making the trip by bus.

The temperature was in the low 90s and not uncomfortable as long as the bus kept moving. The stops immediately started sweat pouring out of every pore. The trip was a bit over two hours to Cartagena, where the bus terminal was even more primitive than the one in Baranquilla. It was not lacking taxi drivers and hordes of baggage carriers, all with dreams of Yankee gold not well concealed. I got the taxi fare down from \$10 to \$2.50 and we were on our way through Cartagena to the Hilton, an air-conditioned luxury respite from the heat and poverty everywhere else.

They even had an ice machine on our floor! We unpacked, relaxed, and had a nice buffet dinner at the hotel. The food was superb. I really needed the rest, not so much from the rigors of the taxi and bus rides, but from the tensions of the previous week.

We'd started out Saturday night with a trip to Chicago. Now one thing you should know about Eastern Airlines is that when you go on a trip just about anywhere on Eastern, you go through Atlanta. Just as Federal, I think it is, ships all packages to Memphis and sorts them, Eastern ships all passengers to Atlanta and sorts them out for their destinations.

Over the next few days we flew Boston-Atlanta-Chicago-Atlanta-Houston-San Antonio-Atlanta-Ft. Lauderdale-Atlanta-Miami-Baranquilla-Miami-Boston. We sure got to know the Eastern Ionosphere lounges at Atlanta.

The first stop was Chicago and the summer Consumer Electronics Show (CES). This was at McCormack Place and was huge. While there was little there in the ham field, the two days I spent there were still well invested. I do have to keep up with home computers, the latest in satellite receiving systems, and discover gadgets such as the new Brother \$200 dot-matrix typewriter with a 16-character

\$\$ HOME-BREW II CONTEST \$\$

It is not too late to submit an entry for *73*'s Home-Brew II Contest. Until October 1, we'll be looking for articles describing the best home-brew projects for under \$50. The winners will share \$500 in cash prizes. For complete details, see page 6 of the June, 1982, issue of *73*.

Micro Modem

—a RTTY TU designed for computers

This article describes an easy-to-build AFSK (audio frequency shift keyed) modulator and demodulator unit specifically designed for microcomputer RTTY operation. I take the liberty of using the term *modem* here in describing this unit since it is the common computer-related term for devices which perform digital-to-audio signal conversions [mo'dem (mō'dəm) n. an acronym for the term *mo*dulator-*dem*odulator. A device used for communicating digital information over analog transmission systems, such as telephone or radio]. Conventional RTTY terminology defines this as a terminal unit.

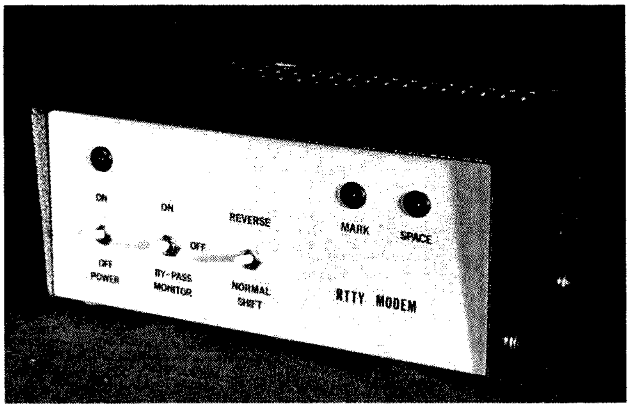
I would like to start by telling you a little about how and why I decided on the particular design I chose. I don't know about you, but I frequently find it frustrating to read a construction article and not have the author tell me how his design is different from other similar designs, in what ways it is better, and what led him to take his approach. I believe you can appreciate the result more when you know the rationale for its being.

I knew very little about RTTY mode when I started. I read back issues of *73*, picked up a copy of the *RTTY Handbook*,[1] and talked to friends. I soon learned the basics and realized that there were only two things preventing me from getting on the air—a program for my microcomputer and a modem to convert RTTY AFSK tones to digital TTL-level signals, and vice versa.

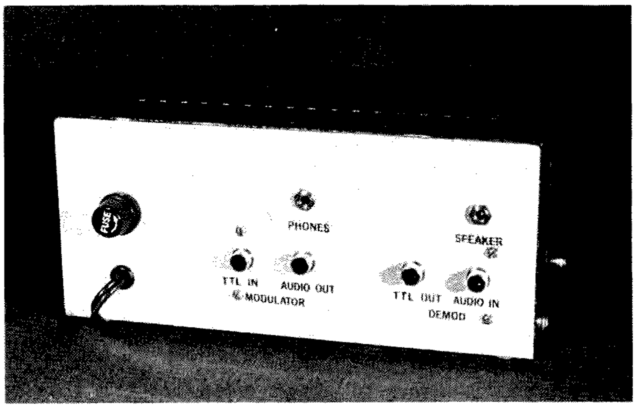
Writing the send-receive computer program to translate serial Baudot data to parallel ASCII (for the video display), translate parallel ASCII (from the keyboard) to serial Baudot, and manage the keyboard and display operation was not as difficult as I had imagined. Again, previous *73* articles and the monthly RTTY Loop column by Marc Leavey WA3AJR were extremely helpful. The June-July issues of 1978 and 1979 contained programming flowcharts and descriptions which are easily adaptable to most any type of computer.

The next step was deciding what to do about a modem, or terminal unit. There seemed to be an abundance of TU gear available from various manufacturers, but there were a couple of problems with nearly everything I saw. First, the prices were out of line with what I was willing to pay. Second, most had features (for example, loop power supplies and autostart) which were for users who were operating conventional electromechanical TTY terminals, not computer terminals. Other features such as wide (850-Hz) shift and CRT tuning indicators were likewise judged as not necessary for my initial system.

The only other avenue open to me was to consider building my own terminal unit. From my research into the various ham magazines, I found numerous TU construction articles. Some described only modulators, others only demodulators, and still others described complete units. I was looking for something that was relatively simple, inexpensive, and yet would give me good operational perfor-



Front view of RTTY modem.



Rear view of RTTY modem.

mance under typical HF RTTY conditions—and would work with my microcomputer.

Selection of an AFSK modulator was settled when I saw the article in *73* entitled "Experimenting with Tones."[2] The Exar XR2206 function generator IC can be easily connected as a very stable two-tone oscillator and can be keyed using a TTL-level input. A breadboard version of a 170-Hz shift generator confirmed my feeling that this was the circuit I was looking for. More on this later.

Selection of a demodulator circuit was a different and more difficult matter. The designs based on phase-locked loops (PLLs) like the 565 and the 567 appealed to me because they are inherently frequency selective, relatively immune to noise, and are specifically intended to perform FSK demodulation. Furthermore, they are simple to work with and are inexpensive.

I first breadboarded a circuit based on the 565. This worked fairly well but seemed much more sensitive to noise and QRM than I was comfortable with. Too, it required a relatively large number of components external to the IC for filtering, signal conditioning, and TTL-level conversion. After a while I realized that the same functions could be accomplished using the more comprehensive capabilities of the 567 tone detector IC and could be done with considerably fewer external components. The 567 also operates on a 5-volt supply which means that no TTL-level conversion is required on its output.

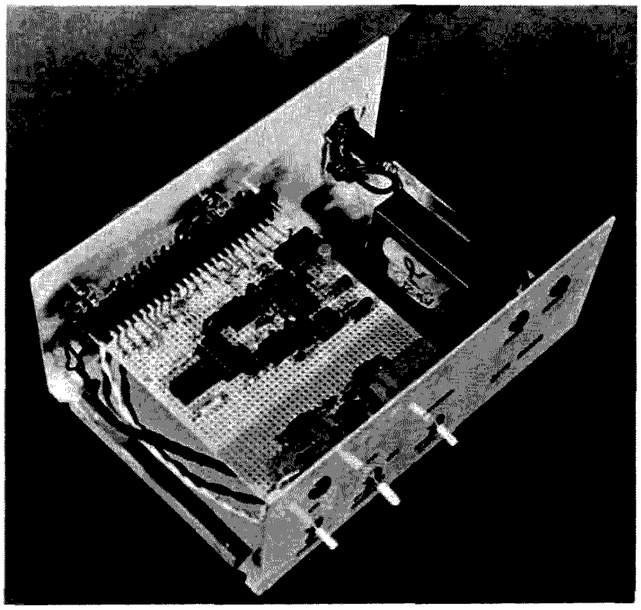
Most published designs of 567-based demodulators use the single tone detect technique in which only one 567 is set up to detect only one half of a RTTY signal—either mark (2125 Hz) or space (2295 Hz). Absence of the desired tone is interpreted to mean presence of the opposite tone. In other words, if the detector is set to look for mark, any time a mark is not being received, it is assumed that a space is being received. Obviously this assumption can be all wrong under conditions where fading and noise are causing signal outages. Also, it makes tuning difficult because CW signals look like RTTY to the detector. You must actually listen to the signal to determine the difference.

Even though I felt that some of the designs I had seen were less than ideal, I also felt that I wanted to use the PLL approach—specifically the 567. Basically, it seemed that a demodulator based on two PLLs, one for mark and another for space, would be the most significant improvement. I would discover later (after having breadboarded a version of this type of circuit) that there were other improvements which could be made.

One of the things I learned about the 567 is that its detection bandwidth is extremely dependent upon the level of its input signal. Most designs I have seen do not attempt to manage the bandwidth, but rather attempt to simply keep input level below the maximum at which the device will still function. Below that maximum, varying input levels cause bandwidth also to vary over a wide range. A consistently small bandwidth would be preferable in order to reduce the effects of QRM. This meant that I would want some type of limiter in my design which would maintain a minimum input to the 567.

Another characteristic of the 567 that caused me concern was the fact that the output will "chatter," or bounce, briefly when turning on. This is somewhat dependent upon certain combinations of input level, component values, and how far off center frequency it is operating. This apparently causes no problems when this type of circuit is used to drive conventional electromechanical TTY gear because of the relatively long response time of its components. It can be a problem, however, when used to drive a computer terminal or other digital logic devices. This problem also would have to be solved in my demodulator design.

Let's take a look now at an overview of the circuit I finally decided upon.



Interior view. 22-pin PC board plugs into socket mounted on rear panel.

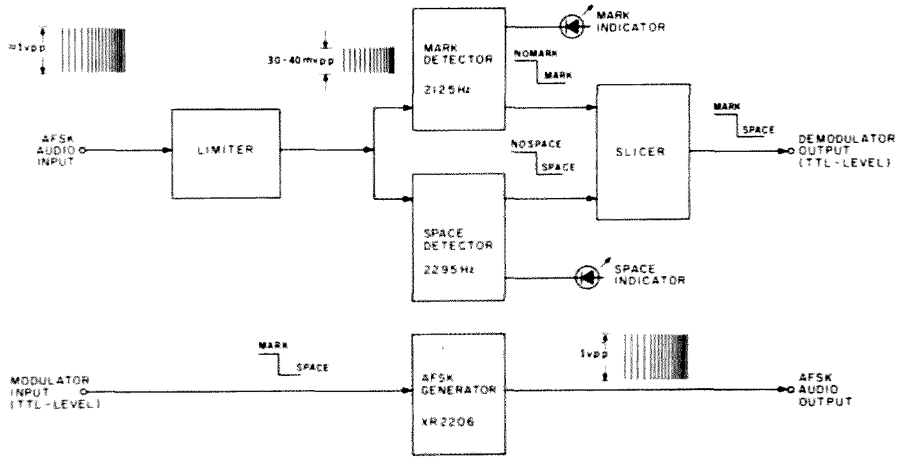


Fig. 1. Block diagram of RTTY modem. Top is demodulator; bottom is modulator.

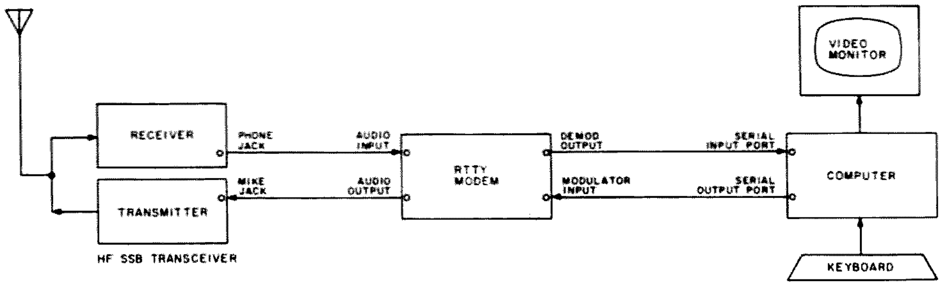

Fig. 2. RTTY modem and computer in an amateur station.

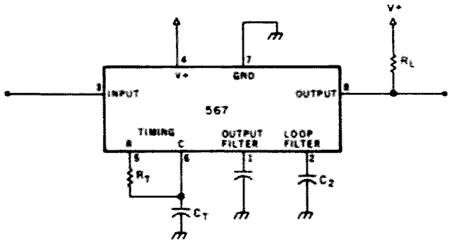

Fig. 3. Basic 567 tone-detection circuit.

Overview

Fig. 1 shows a block diagram of the complete RTTY modem, both the modulator and demodulator.

The modulator generates either mark tones of 2125 Hz or space tones of 2295 Hz, depending upon the value of the keying voltage on its input. The keying input represents serialized Baudot data from an output port on the microcomputer. Each Baudot character is made up of mark and space bits, where a mark is high and a space is low. The output is nearly a pure sine wave, amplitudes of the mark and space tones are equal, and there are no switching transients.

The demodulator portion of the modem consists of a limiter, dual PLL detectors, and a slicer. The limiter controls input level and ensures consistent detector operation. Two independent tone detectors are set to react to the presence of input frequencies on, or very close to, 2125 Hz and 2295 Hz. The passbands are narrow enough to prevent erroneous locking onto nearby QRM and also narrow enough that the two passbands do not overlap. LED indicators attached to each section serve as tuning aids. Alternating flashes indicate a legitimate 170-Hz-shift RTTY signal.

Output from the individual detectors is fed into a slicer. Here the two inputs are combined back into a single output going to the input port on the microcomputer. Again, mark is high, space is low.

Fig. 2 shows how the modem fits into an amateur station.

567 Tone Decoder IC

In order to understand how the RTTY modem works, it is necessary to know a little something more about the 567. Basically, it is a phase-locked-loop tone detector which provides an open-collector output on pin 8 (see Fig. 3). When an input signal is present on pin 3 which falls within its capture passband, the output shorts to ground. Thus, if the output is "pulled up" to 5 volts through an appropriate resistor, R_L (current must be limited to 100 mA or less), TTL-level transitions between 0 and 5 volts can be achieved. External components attached to other pins set center frequency, bandwidth, and output delay.

For the purpose of detecting RTTY signals, we want a center frequency of either 2125 Hz or 2295 Hz. In Fig. 3, R_T and C_T determine center frequency by the approximation: $f_o = 1/(R_T C_T)$.

Now, for RTTY, we want a minimum passband, for two reasons—to eliminate QRM and to prevent detection of both mark and space tones at the same time. Remember, they are only 170 Hz apart. C_2 and input voltage level V_i determine bandwidth. The formula used to approximate bandwidth in terms of percent of f_o is: BW (% of f_o) $= 1070\sqrt{V_i/f_oC_2}$, where C_2 is in μF and V_i is in volts rms.

A word of caution: The formula becomes less usable at lower values of V_i (near 20 mV) combined with values of C_2 below about .5 μF and f_o values in the 2000-3000 Hz range. Actual bandwidth realized is less than predicted by the formula.

The last characteristic of the 567 with which we must be concerned is output delay. All PLLs exhibit some delay to lock onto an input signal and confirm its presence on its output. This is expressed in terms of number of cycles (of input frequency). For 60-wpm RTTY, each bit (a Baudot character is a start bit, five data bits, and a stop bit) is 22 ms wide, except the stop bit which is 31 ms. We therefore want output delay to be something considerably less than 22 ms—which is 46 cycles for a mark bit (.022 sec. × 2125 Hz) and 50 cycles for a space bit (.022 sec. × 2295 Hz).

Unfortunately, output delay is controlled by C_2, and in a way that is opposite to the way it affects bandwidth. In other words, for large values of C_2, bandwidth is small and output delay is large. We would rather have both small. I said earlier, however, that at low input levels and low values of C_2, bandwidth is significantly smaller than predicted by formula—and small output delays are obtained at the same time! This is clearly a case of having your cake and eating it, too.

The circuit described in this article has a measured output delay of about 15 cycles, or about 7 ms. This means that the mark detector, for instance, takes 7 ms to lock onto a 2125-Hz input, resulting in an output which is only 15 ms wide, not 22 ms. If my circuit were of the type that uses only one PLL, the output would be severely distorted. Marks would be too short and spaces would be too long. Using dual detectors with an appropriate slicer eliminates this problem.

Demodulator Circuit Description

Refer to Fig. 4. A jack is provided to attach a speaker for monitoring input audio from your receiver. A switch allows monitoring at attenuated volume, bypassing the attenuator for tuning purposes, or not monitoring at all.

The limiter is a high-gain amplifier using a 741 op amp (U1) which has parallel reversed diodes in its feedback path. The effect of the diodes is to limit output to about .6 volts—the forward-bias drop across a silicon diode. Gain of the amplifier is very high for low-level input, before the diodes begin fully conduct-

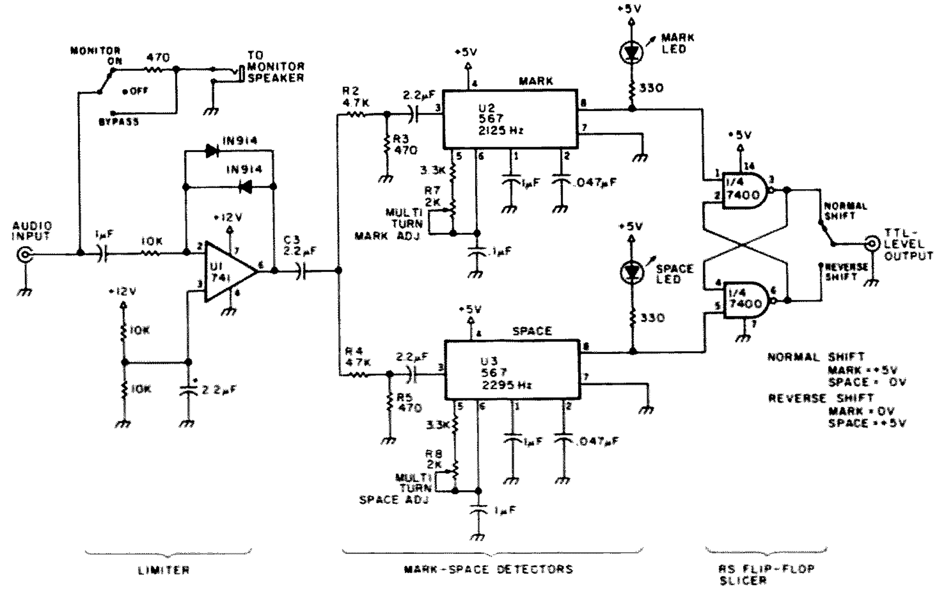

Fig. 4. Demodulator circuit. Audio input is from phone output of receiver. Output goes to computer input port. LEDs indicate RTTY signal.

ing. As input increases, gain decreases logarithmically due to the small-signal conduction characteristics of the diodes. If you look at the limiter output on a scope, you will not see a flat-top square wave, but instead a waveform with more rounded tops. Coupling capacitor C_3 is required to block the dc bias (+ 6 V) on the output of U1.

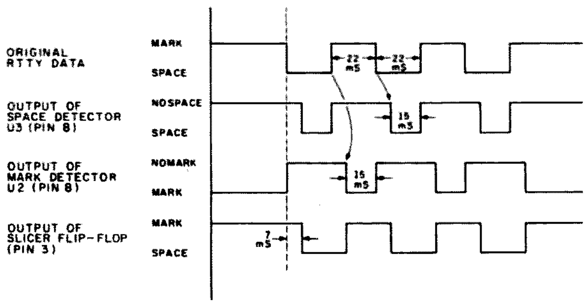

Fig. 5. Slicer reconstructs original data from separate detector outputs. Notice that distortion is corrected and that the ouput signal has been delayed by 7 ms from original.

Limiter output is further reduced by voltage dividers R2-R3 and R4-R5 to approximately 30 mV rms which is used as input to PLLs U2 and U3. This sufficiently low-level input ensures a bandwidth of only about 100 Hz, or ± 50 Hz either side of center frequency. Trimpots R7 and R8 set center frequency.

Output on pin 8 of U2 and U3 falls low when the expected frequency is detected, which turns on the associated LED. I mentioned before that this output contains a 7-ms delay and also has approximately 1 ms of chatter.

These outputs are fed into a slicer which is simply an R-S flip-flop constructed of two NAND gates. Actually, the slicer in this circuit is intended to do more than simply recombine its two inputs into a single output. First, it serves as a debouncing circuit to eliminate the chatter I just mentioned. Secondly, it nullifies the output delays of the PLLs. To illustrate how this works, refer to Fig. 5. Individual output delays of each of the two detectors are shown as being exactly equal when, in reality, they may differ a little. Anyway, the slicer output is almost entirely free of distortion and is delayed in time by 7 ms.

The final advantage of the flip-flop slicer is that it only changes states if both mark and space tones are present. If noise or momentary loss of signal occurs during a single bit, its output state is maintained until the opposite tone is detected. This certainly doesn't solve all types of signal problems, but it helps.

A switch is provided on the output to select normal or reversed shift operation. Most amateurs use normal shift (mark = low tone, space = high tone) and lower sideband on HF RTTY.

Modulator Circuit

Fig. 6 shows the AFSK modulator portion of the RTTY modem. It is based on the XR2206 function generator IC. Although this device has many uses, it is especially designed for two-tone AFSK generation. Read the excellent article by W2FPP for additional information.[2]

Mark and space frequencies are independently set by timing resistor trimpots R9 and R10 respectively. The timing capacitor between pins 5 and 6 is common. Output on pin 2 is a sine wave and is phase-continuous when switching, which makes it well suited for SSB FSK modulation. Component values should be high quality for best results.

The keying signal is applied to pin 9 and is a TTL-level signal directly from the microcomputer output port. + 5 volts selects the mark generator and 0 volts selects space.

Resistor R11 (10k) controls output level. This results in approximately 1 volt pp to the microphone input of the transmitter. Other levels may be obtained by changing this resistor.

The earphone jack was installed so that the output can be monitored for testing purposes.

Power Supply

The power supply is rather straightforward (Fig. 7). The center-tapped transformer serves both the + 5- and + 12-volt supplies. Low current requirements allow the LM340 regulators to be mounted directly to the PC board without heat sinks.

Construction

I built the RTTY modem on a Radio Shack 4½"× 4" universal PC board with a dual 22-pin edge connector and mounted everything into a 3½"× 8"× 6" metal box (see photos) also available from Radio Shack. Fig. 8 shows the component layout and pin allocation that I used. Layout is not critical, which allows a lot of flexibility in how you might build your own version. I intentionally left an area open on the board to give me room to later build a bandpass filter to help reduce QRM problems.

When I decide to build it, I'll just insert it in the circuit ahead of the limiter on the demodulator. The frequency-adjust trimpots for both the modulator and the demodulator are mounted on the board such that they are easily accessible when the board is plugged into the cabinet.

When working with TTL devices, it is normally good practice to add decoupling capacitors between the + 5-V supply pins and ground. Although not shown in the circuit diagram, disc capacitors 0.1 to .01 μF with short leads should be attached to the 7400 (pin 14) and to each of the 567s (pin 4).

Most parts, including the trimmer pots and the XR2206 IC, are available from Jameco Electronics, San Carlos CA 94070.

Alignment

Use a frequency counter to align the AFSK modulator. Attach the counter to the output jack, ground the input jack (or pin 9 of the XR2206) to select the space timing circuit, and then adjust trimmer R10 to get 2295-Hz output. Now remove ground on the input jack (or pin 9) which selects the mark timing circuit, and then set trimmer R9 to get 2125-Hz output. This completes modulator alignment.

Now align the demodulator. First, the mark detector. Apply a 1-V pp 2125-Hz sine wave to the demodulator input jack. I use the frequency marker signal from my transceiver, adjusted to frequency using the frequency counter, and adjusted to level using a scope. Adjust mark trimmer R7 until the mark tone LED indicator comes on. Now find the position which is midway between the two positions where the LED goes off. The center frequency should now be at or very near 2125 Hz. Alignment of the space detector is done in the same manner for a frequency of 2295 Hz.

At this time, you should verify that the bandwidth of each detector is no more than 150 Hz, or ± 75 Hz on either side of center frequency. With your receiver feeding into the input, slowly tune across a heterodyne or marker tone. One of the LEDs should light briefly and then the other. There should be a "dead spot" in between where neither LED is lit. There should not be any time when both LEDs are on for the same tone. If you have problems with these verification tests, check alignment of each detector and check to make sure that the input on pin 3 of each 567 is no more than 30-40 mV pp.

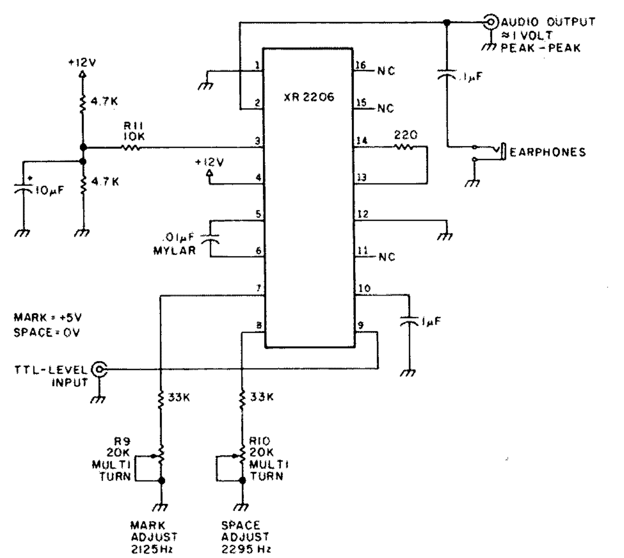

Fig. 6. AFSK modulator circuit. Input comes from computer. AFSK output signal goes to microphone input of SSB transmitter. Earphone jack is for monitoring output.

Operation

Using the modem on the air is pretty simple. When transmitting, the AFSK modulator is driving your transmitter at 100% duty cycle. So make sure that you set your microphone gain for reduced rf power output to protect your finals.

In receive mode, tune your receiver around the RTTY portions of your favorite band and then look for the distinctive blinking of the mark and space LED indicators when a valid RTTY signal is found. Make sure that your receiver's audio output level is sufficiently high to produce good, solid LED flashes. Also, you will usually want the Shift switch in the Normal position.

Summary

The RTTY modem was designed to provide inexpensive yet reliable operation for the amateur who wants to quickly get on AFSK RTTY. Because I wanted to use it with a microcomputer terminal, I attempted to eliminate some of the problems of other designs which were associated with conventional TTY terminal operation. The design is simplified by the use of a single IC modulator and a demodulator based on dual PLL tone decoders. Dual decoders have advantages over designs which use only a single decoder: They are easy to tune, immune to certain types of signal fading, noise, and distortion, and will not react to CW signals.

Although built to interface directly to my computer input/output ports, other types of interfaces, such as RS232C, current loop, or UART, could certainly be used if the appropriate circuitry is added. This makes no difference to

F1 for the Hot Water 101

—all the way with FSK!

The Heathkit HW-101 is one of the most popular transceivers on the market. It is available for a fraction of the price of some of the fancy rigs, uses tubes, and has plenty of room on the inside for modifications. A comprehensive technical manual comes with it which includes X-ray views of all the boards and a complete explanation of how it goes together—mechanically as well as electrically. Many used HW-101s are available at hamfests and in the various ham magazines. The LMO (vfo) is stable and the rig would seem to be an ideal candidate for RTTY. The only problem is a very limited amount of information about how one might go about putting this jewel on RTTY.

Faced with this dilemma, I decided to grab the bull by the horns and see what could be done. There are two methods of obtaining FSK from a sideband transmitter: 1) the AFSK method and 2) the FSK method.

The AFSK method consists of feeding audio tones into the microphone jack while running the transmitter in the USB or LSB mode. If carrier and unwanted sideband suppression is sufficient, the resulting signal is identical to a true FSK signal when detected on the air. The drawbacks to this method, however, are many. Many transmitters do not have sufficient carrier suppression and it is easy to over-drive the transmitter and cause splattering just as is heard so often on the SSB bands. Another problem is that when using 850-cycle shift, the standard tone of 2975 Hz falls very close to the edge of the audio passband of the transmitter and is therefore attenuated, resulting in uneven power between mark and space tones on the air. Some rigs will not pass this tone at all.

Irv Hoff W6FFC has written several articles explain-

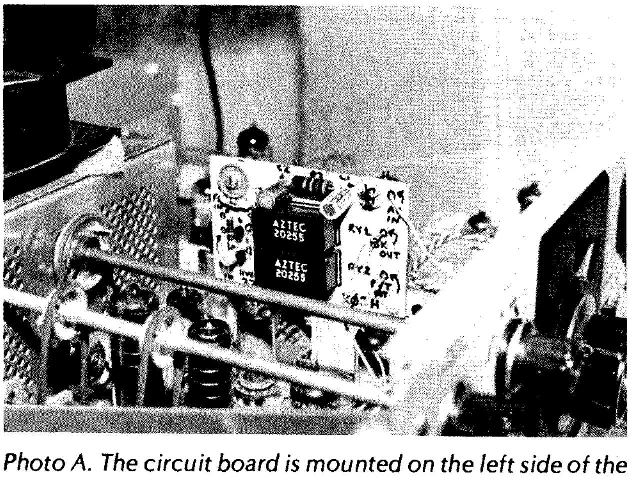

Photo A. The circuit board is mounted on the left side of the LMO. The shift-adjust cap can be seen on the upper left corner of the board.

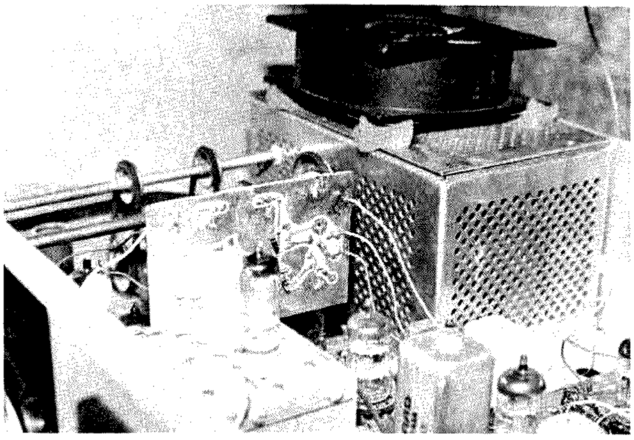

Photo B. Rear view of FSK board showing wires from computer.

ing the pros and cons of using AFSK input to SSB transmitters and transceivers to obtain FSK on HF.[1,2] The instruction manual which comes with the HAL AK-1 AFSK generator has an excellent discussion and summary of the important points. At least one of these sources should be reviewed before attempting to obtain FSK in this manner. Remember, if the FCC detects any unwanted sideband or carrier on your signal, a pink ticket will follow.

The true FSK method is simpler and safer if it can be obtained. Unfortunately, many transmitters have vfo's that are very difficult to modify. Then, too, there is always the possibility of destroying the built-in stability if one tampers with a vfo without sufficient knowledge of the principles involved.

A close examination of the HW-101 schematic shows that in the CW mode, the balanced mixer is unbalanced and a crystal-generated carrier is allowed to pass through. It was a simple matter to connect a trimmer capacitor across this crystal and observe that the desired shift in the carrier frequency occurred.

The circuit of Figs. 1(a) and (b) was developed and has been used at KØJH to work 62 countries and 44 states in two months, running the HW-101 barefoot with only 75 Watts output into a mini-quad antenna on a thirty-foot mast.

The circuit assumes that you are running a computer with TTL output levels. If you have RS-232 output signals, simply add the circuit of Fig. 2 to convert the RS-232 to TTL signal levels. If you are running a normal 120-V-dc 60-mA teletype loop, you can use the circuit of Fig. 3 to obtain a TTL output which will drive the FSK input to the transmitter, but you will have to devise another method of turning the transmitter off and on. Doing it manually would be the easiest method. If any of the TTL signals are inverted, just add a hex inverter such as the 7404.

After trying several solid-state methods with less than complete success, relays were used to do the keying of the transmitter and the switching on and off the air. Perhaps someone else can modify the circuit to accomplish the same thing with a diode or transistor switch and eliminate the relays.

Power to run the relays was borrowed from the filament line which is easily accessible at the pilot lamp socket attached to the LMO. A simple rectifier and filter are used to get approximately 12 V dc. See Fig. 1(c). Relays are miniature magnetic-reed types and are available from two sources that I know of: ETCO 066RL[4] ($.99) and EDLIE DG1407[5] ($.79). Other relays of a similar fast-acting type will work just as well.

The entire circuit is laid out on a printed circuit board in about fifteen minutes using a resist pen. It is not reproduced here because the exact pattern will depend upon the actual components used. Nothing is critical so no special talent is required. There is no reason why wire-wrap or any other method of construction could not be used. The circuit board is mounted to the left side of the LMO, using existing metal screws (see Photos A and B).

The external lines are brought into the HW-101 through a molex® connector (Radio Shack 274-229/239) which fits nicely into the hole provided on the rear panel of the transceiver with a minimum of filing (see Photo C).

The connection to the CW crystal, Y3, is best made at pin 17 of the mode-switch rear wafer. The proper pin can be identified by the black wire which runs from it to a hole labeled "22" on the modulator circuit board right beside crystal Y3.

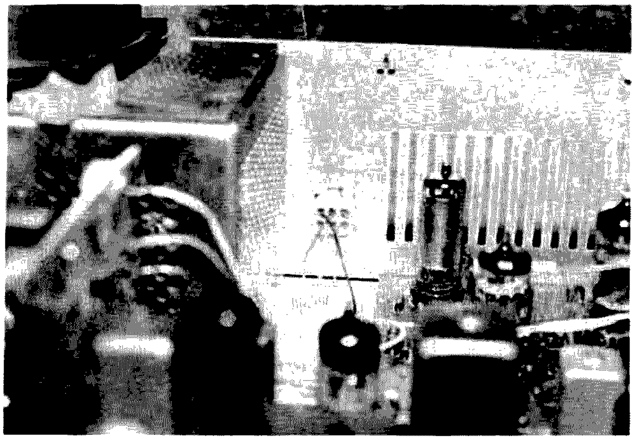

Photo C. The molex® connector (Radio Shack 274-239) is installed on the rear panel.

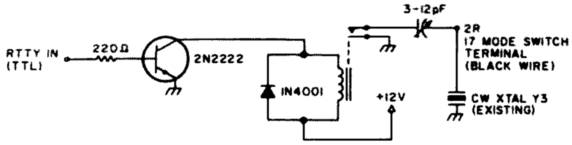

Fig. 1(a).

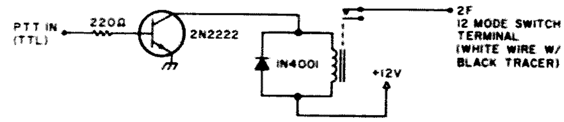

Fig. 1(b).

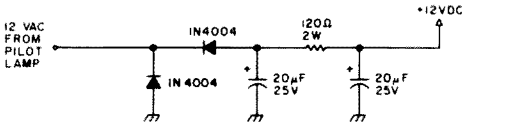

Fig. 1(c).

The connection to the PTT circuit is a little more complicated. The logical place to connect would be on the mode switch at pin 20 or to tube V12, pin 8. The mode-switch pin 20 is not easily accessible, however, and pin 8 of V12 is on the opposite side of the modulator circuit board from the place chosen to mount the FSK board. The point decided upon was the white wire with black tracer which connects to mode-switch pin 20 and then is routed from underneath the mode switch to the rear of that switch. A small piece of the insulation of this wire was carefully scraped away and the PTT connection was made to the wire.

To adjust the FSK circuit for 170-cycle shift, simply put the transmitter in the CW mode and, while connected to a dummy load, key the transmitter through the PTT circuit. Either tune your receiver until the proper mark frequency is obtained as determined by your RTTY terminal unit or, using a frequency counter, adjust the receiver until an audio output frequency of

2125 Hz is obtained. Now set the equipment to send a steady space or open your loop if using a high-level (120-V-dc, 60-mA) loop, and adjust the trimmer capacitor for a proper space as seen at the terminal unit or until the frequency counter indicates a frequency of 2295 Hz. (2295 − 2125 = 170-Hz shift.)

Provisions in this circuit are for 170-Hz shift only since nearly 100 percent of ham and MARS activity is now using that shift. If you need 850-Hz shift for some reason, simply add another trimmer capacitor in parallel with the existing one, arrange to switch it in for 850-Hz shift, and adjust it until 850-Hz shift is obtained (2975 Hz).

Now tune the HW-101 up in the CW mode as you usually would, but decrease the output power to around 60 Watts by backing off on the mic/CW level control. If you have the 400-Hz filter installed, be sure the filter control is in the SSB position. If you have not done so, you will soon see the need for VE3IOI's sidetone volume control modification.[3] Without some method of controlling the sidetone, you will be subjected to a piercing tone during the entire time the HW-101 is transmitting RTTY.

If you have never been on RTTY before, you are in for a treat. There isn't another mode which affords the quality QSOs that RTTY does. Everybody wants to chew the rag, even the DX stations in most cases. The average QSO lasts for an hour. You will also be amazed at the really good signals you will hear from stations who are running anywhere from 10 to 100 Watts. Probably 60 to 70 percent of all RTTY signals are being originated from transmitters putting out less than 100 Watts. One chap in Italy called me for a signal report and when I gave him an honest 589, he explained it was his first RTTY QSO using his new TS-130V which puts out 15 Watts. The HW-101 is a high-power rig by comparison. Try it—it's a ball.■

No-Frills RTTY

—$200 and you're on the air

Luck Hurder WA4STO
Fort Valley Route
Seven Fountains VA 22653

Yup. Here's another article on radioteletype, folks. But before you turn the page with one hand (while stifling a yawn with the other), consider the following. I've got somewhat less than $200 invested in my RTTY gear and I'm not only going to show *you* how to do likewise, but I'll even give you a few pointers on how to hook all these weird gizmos together. The result? Loads of fun with no muss, no fuss.

Photos by Forest McCarty

Photo A. On the left is the Model 19 printer, with the Model 14 tape reperforator to the right. The sour look on my face is representative of how you will feel after lifting your first printer! But remember, the price is right.

What you *won't* find in this article is a lot of complicated math or any incredibly-expensive equipment. Don't look for any computer programs and don't expect a long list of formulas or incomprehensible graphs. Just pay attention to the pictures, chum, and enjoy the thrill of RTTY as much as a growing number of us are doing now. Got yourself positioned in your favorite chair? Super. Here goes.

First off, I'll make a couple of basic assumptions that should apply to you and your station. Assumption number one is that you presently have a transmitter/receiver (or a transceiver) lurking about somewhere and some sort of wire, aluminum tubing, or whatever that you can press into service as an antenna. Nothing fancy, mind you. If it had to be fancy, I wouldn't be writing about it! Anyone with the misfortune of having visited my shack will jump at the opportunity to verify that my antennas are among the worst possible. So whether your goal is HF or VHF RTTY, do what you can. One of my favorite sayings is that *any* antenna will work—but some do so better than others . . .

The second assumption is that you have a desire to become active in RTTY. Perhaps you have friends who consistently time out the local repeater with details about their latest zillion-dollar efforts at computerized transmission of the Miss April centerfold. Or maybe your programmable scanner locked itself up solid on 147.1 MHz the other night with those weird deedle-deedle-deedles that you'd just love to snoop in on. OK, OK—just hang in there for a few more para-

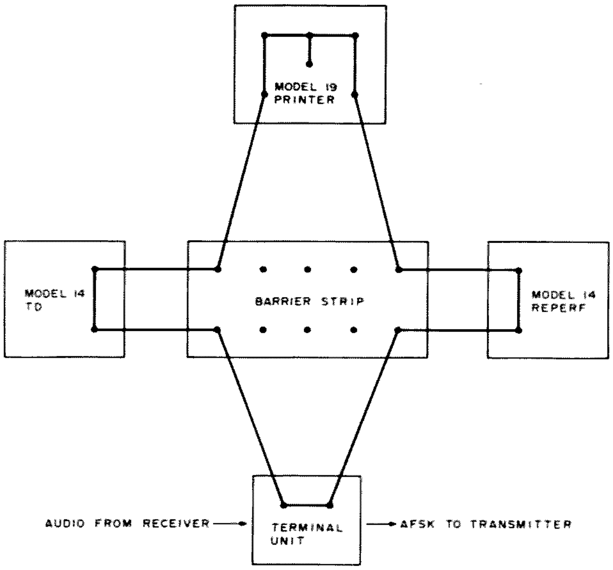

Fig. 1. The "local loop" is nothing more than a dc loop of 60 mA connecting all of the RTTY station equipment. The use of a large barrier strip allows for additional pieces of equipment to be inserted into the loop with ease.

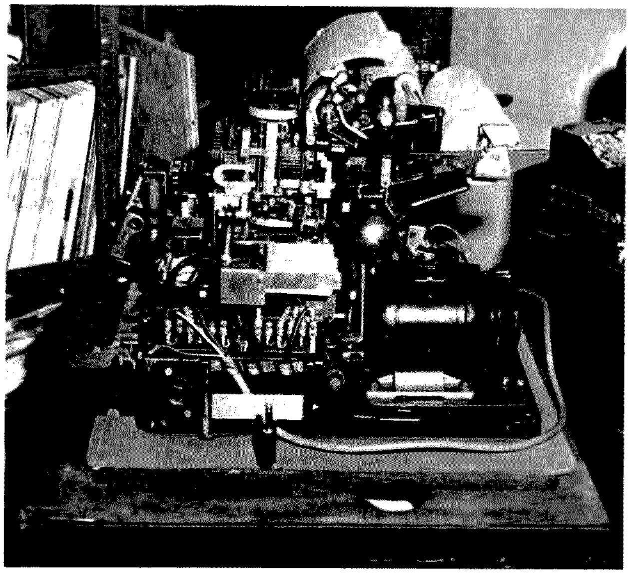

Photo B. The Model 19 printer with cover removed. Note the terminal strips with all the wires going every which way. Don't be intimidated! Only two sets of connections are really necessary, one for the ac and one for the dc loop. See Fig. 1 for loop details. Also note use of ¼-inch phone plugs for easy changes in equipment location.

graphs and you'll be able to further your studies into human anatomy and/or the fine points of RTTY espionage!

The above assumptions are probably valid for the huge majority of you who have gotten this far into the article. And, let's face it, the theory hasn't become too deep yet, and you've not spent a dime.

Photo A shows yours truly and my mechanical marvels. They're marvelous for two reasons. First, they're older than I am, while probably working as well as the day they were built. And second, they were free! This particular Model 19 and all the associated tape gear was obtained gratis through the Army MARS program. Not that I'm suggesting that you join one of your state MARS teams just to get free equipment, but it certainly is one of the benefits that one hates to pass up, and you'll learn a lot if you participate in MARS.

I'd also like to point out that in the past year, five complete teleprinters have passed through my hands at no charge. Two were from the MARS program and three were from fellows who were glad to get them out of their shacks! Their loss was my gain, and there's absolutely no reason why you can't do the same. Spread the word on the repeaters, request help from your friends, write letters. Do anything reasonable, but keep at it. There's more free equipment out there than you'd dream possible. I've had to drive from where I live in the mountains of the Shenandoah Valley all the way into the suburbs of Washington DC more than once—a distance of about 100 miles each way. There are only a couple of reasons I'd drive there these days, and one is free RTTY gear!

Assuming that you've rounded up one or two of these fine old machines, now's the time to hook up your terminal unit.

"What's a terminal unit?" you ask in dismay! Well, without going into detail, the terminal unit (or TU) is that neat little gizmo that converts those deedle-deedles into something that your RTTY machine can use. There's a great profusion of TU equipment advertised these days, but if you'll take a glance at the accompanying photos you'll see the one I've been using. It's the TU-170, made by Flesher Corp., and their advertising is abundant in *73* as well as other magazines. In kit form the TU-170 was $150, and let me tell you, pal, if *I* can build it, *you* sure as heck can. Honest.

This particular TU has many features, including a gadget that will allow you to transmit RTTY as well as just print it. Also, it has an autostart feature which will allow you to receive RTTY

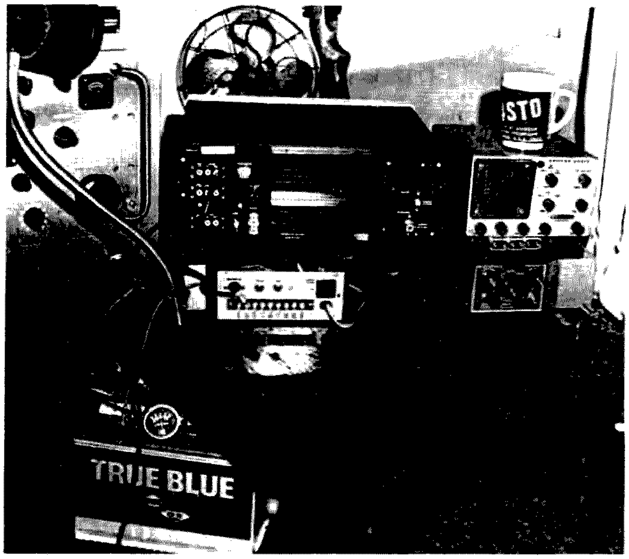

Photo C. The only interconnection between the transceiver and the terminal unit required for receiving RTTY is from the "patch out" jack to the "receiver audio" lugs on the TU. The printer is normally plugged into the ac receptacle on the TU for autostart operation.

AT LAST!

This service will be available nationally. Lab tested & time proven modifications professionally installed in your amateur Handy-Talkie 2M, 220, 440, MH2 transceiver by Henry Radios warranty technicians (KNOWN AS "A&W PRODUCTIONS")

HAVE ALL PL TONES AVAILABLE AT YOUR FINGER TIPS

Outboard the dip switch! Have it neatly inlayed into the back cover of your Handy-Talkie making all 32 PL Tones Selectable at a moment's notice.

$25 Got your own PL? Send it to us with your Handy-Talkie unit and we do the professional installation for you.

$55 We will install a new PL and inlay the dip switch into the back cover of your Handy-Talkie ready to operate.

Send us your Handy-Talkie unit and a check or money order plus $3.50 for shipping and handling payable to **A&W PRODUCTIONS, INC.**

For **TEMPO** units the dip switch is inlayed into the Push-to-Talk bar. The **TEMPO S-15** will have the dip switch inlayed into the back cover.

$45 We will install a **NEW BATTERY BEATER** in your **TEMPO S-1, S-2, S-4, S-5 READY** to operate. Your New Battery Beater will use the same jack as the charger with no new holes and regulation circuits built into unit. Comes with Cigar Lighter Adapter with internal fuse.

CONTACT A&W PRODUCTIONS FOR SPECIAL MODIFICATIONS YOU MAY WANT TO HAVE DONE. WE SPECIALIZE IN THE TEMPO HANDY-TALKIES.

WE ARE AN OFFICIAL "TEMPO" REPAIR STATION
ALL WORK GUARANTEED FOR 30 DAYS. SEND YOUR HANDY-TALKIE AND A CHECK OR MONEY ORDER TO:

3305 Pico Blvd., Santa Monica
California 90405 (213) 828-9310

✓164

messages while you're at work. But the nicest thing I'd like to pass along to you is that the people at Flesher are just as interested in getting your TU to work as you are. I've had to pull them away from whatever they were doing on several occasions on the telephone and they were *always* extremely helpful. I wrote and told 'em so, too. You wouldn't believe the foolish questions I've had to ask them, but they never flinched. Thanks, folks!

OK, now you've got your RTTY machine and you've got a TU and you're standing around wondering how in Sam Hill to begin hooking all this gadgetry together. Relax! Better yet, don't relax. Jump right up and run over to your collection of back issues of *73*. The September, 1977, issue is crammed full of much-needed information on the care and feeding of these old clunkers. What's that you say? Those nerds who've been running their mouths on the repeater refuse to give back your copy of the September issue? Never fear. Wayne Green sells back issues, and if he's all out, see if you can get an SASE into my mailbox and I'll try to answer your questions.

At any rate, take a peek at the accompanying closeup of the Model 19 printer (Photo B). This particular machine really had me buffaloed for an embarrassing number of weeks. I'd found several articles and books that told me how to hook up a normal printer (which has three terminal strips), but not a word about this particular beast. One of my MARS friends finally said, "Hey dummy! All they've done is combine the three normal strips into two," which explained why all my gyrations in the shack failed to produce the third strip from within the innards of this antique. You might be lucky enough to have the red and black plugs already there, just-a-waitin' to be hooked *in series* with your TU loop supply (see Fig. 1). If not, you may have to dig around a bit. If nobody has seriously butchered the internal wiring, you'll find the correct connnections with no problems. If you really get stuck, let me know.

One brief word of warning here. Keep your mitts away from the actual loop supply. I'm talking about something like 130 volts at 60 mA. That just might be enough to kill you! I've managed to ignore this advice thrice so far, and *it hurts!*

Now apply audio from your rig to your TU, and you should be able to tune in RTTY signals. Photo C shows how I managed my connections. It took about thirty seconds to figure this part out. The thrill of tuning past a RTTY signal and hearing the printer start chugging away was just super. I couldn't believe that this ancient equipment could possibly work so well! Given a bit of lubrication and a dab of TLC, I expect that these machines will live longer than I will, particularly if I ignore the previous paragraph another time or so!

Photo D shows how I managed to start transmitting. It was very difficult—I merely plugged in the AFSK output from my TU to the mike jack on my transceiver, adjusted the drive, and started typing!

I do, however, feel a touch of moral obligation to the RTTY neophyte. If you're using tubes in the finals of your rig, for Pete's sake, turn down the mike gain or otherwise reduce the power! I've ruined more 6146 finals than I'd care to comment on, and I've gone now to idiot-proof transistors. The rig that I presently use is capable of running all day at full power. Yours might not be so blessed. Find out, if you don't already know. End of sermon.

I've shown you my method for getting on RTTY. This is one of the simplest and cheapest ways I could come up with to obtain the features that I deemed important. I've got loads of ideas brewing in my head that I'm hoping to write about soon, so feel free to write and tell me what you liked or didn't like about this article. All SASEs will be answered.

I would like to express my sincere appreciation to Forest McCarty for his photographical expertise, as well as to Durwood WA4ZBP and all my many Virginia Army MARS friends for answering my never-ending questions. ■

Photo D. Transmitting RTTY is simplicity itself. Just plug the AFSK output from the TU into the mike jack of the transceiver, and enjoy!

Phil Anderson W0XI
3005 West 19th
Lawrence KS 66044

Incredibly Simple RTTY

—receive it on your TRS-80

If you have a transceiver and a TRS-80™, then you have nearly all the equipment necessary to receive radioteletype (RTTY). The only additions required are a 26-statement BASIC program, two TTL integrated-circuit chips, and a demodulator. The program and interface design are presented here, and a demodulator is recommended.

RTTY System

As shown in Fig. 1, a RTTY system might consist of a radio receiver, a demodulator, a computer (in that case, the TRS-80), and a monitor or other form of readout. Most RTTY is sent as audio frequency shift keying (AFSK) via SSB radiotelephony. Hence, when a signal is tuned in on your receiver, it will be heard as two alternating audio tones. Those tones are called the mark and the space—the lower tone being the mark.

The job of the demodulator is to convert those audio tones into a computer-compatible on-off signal. Historically, demodulators have developed a 20-milliamp current signal for direct use with a teletype terminal such as an ASR-33. However, for interconnection to a computer, the demodulator, or demod, must present a logic signal that is compatible with standard logic chips. So, when the AFSK signal is received, the demod converts the lower tone to a logic one and the upper tone to a logic zero or zero volts.

The computer's job, then, is to convert the logic signal from the demod to a corresponding letter code for presentation on a monitor. The majority of the work is done with a BASIC program while the interface provides connection to the demodulator output.

Demodulation

Let's take a look at the demod operation first. Suppose the letter Y is being received. A low audio tone will be received first followed by the start bit, a higher frequency tone. The demod will convert the low tone into a logic high signal, or mark, and the start bit into a logic low signal, or space, at zero volts. The actual code for the letter Y, as shown in Fig. 2, is then received as a sequence of marks and spaces: mark-space-mark-space-mark or high-low-high-low-high. The sequence is ended by a stop bit—a mark. All marks and spaces are 22 ms in duration except the stop which is 31 ms.

For testing of the TRS-80

Fig. 5. 26-step RTTY program listing.

RTTY system, the Kantronics Signal Enforcer™ audio filter was used. That dual filter has a TTL-compatible demod output. When a signal is tuned in, the Signal Enforcer demod output presents a logic high signal for a mark and a logic low signal for a space.

Now let's examine how the demod output can be interfaced to the TRS-80 hardware.

Computer Interface

Since the RTTY signal is only one voltage, either high or low as time goes by, only one signal line into the computer is necessary. However, in order for the TRS-80 to receive it, the signal must be gated onto the memory bus under the control of a "read" signal. In addition, the memory bus must be isolated from outside circuits, so a noninverting TTL logic chip is required.

As shown in Fig. 3, these requirements can be satisfied using two chips, a 74LS02 NOR gate and a 74LS367 gated buffer. The demod output status is transmitted to the memory bus via the buffer when pin 1 is set to a logic low. That is accomplished by executing the BASIC statement A = PEEK(−1). The minus factor sets the highest-order address bit of the address bus on, and the PEEK statement causes the "read" pulse to be issued simultaneously. The address bit is inverted by a NOR gate and then combined with the "read" pulse to provide the activating signal at pin 1 of the buffer.

The resulting data, then read off the memory bus, is inverted and assigned to the variable A. For example, if the demod output is high, the value for A will be 255, but if it is low, it will be set to 254.

A few more comments on the logic interface are in order. The line names at the left of Fig. 3 represent the pin connections to the TRS-80 I/O port. A15-P7 means address line 15 at pin 7; D0-P30 means data line 0 at pin 30; RD*-P15 means read pulse negative at pin 15; the ground connection is at pin 29. The user must supply his own 5-V-dc power source for the interface logic because the TRS-80 connector usually has that pin disconnected. In addition, if desired, the remaining NOR of the 74LS02 can be used to buffer the demod input and drive on the LED.

That completes the interfacing. Let's now take a look at the 26-statement BASIC program to decode and display RTTY signals.

BASIC RTTY Program

Again, take a look at Fig. 2. The standard RTTY 60 format includes a start bit of 22-ms duration, five 22-ms data slots, and a 31-ms stop bit. When no characters are being received, the demod output will be high continuously. When a letter or figure is received, it will commence with a start space. This is our key; we will have the program watch the demod output until a space is received. Then, proper delays can be built into the program so that samples are taken at approximately the center of each data slot.

For example, if a space is detected at B in Fig. 2, then the program will delay 22 ms and sample at 16, delay again for 22 ms and sample at 8, and so on, taking five samples in all.

Now let's take a look at the flowchart for the program as shown in Fig. 4. First, constants are initialized and letters and figures are read in via the data statements to form the RTTY character codes. Then, the program enters a continuous loop. If a space is received, proper delays are generated and samples are taken. If not, the pro-

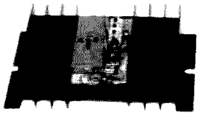
A modular approach...for your own custom-designed ATV system....Here's how

TXA5-4 ATV EXCITER/MODULATOR.$89 ppd

This wired and tested module is designed to drive the Motorola MHW-710 module in the PA5 10 watt linear amp. The crystal in the 100 mHz region keeps harmonics out of two meters for talk back. The video modulator is full 8 mHz for computer graphics and color. Requires 13.8 vdc reg @ 70 ma. Tuned with xtal on 439.25, 434.0, or 426.25 mHz. Provision for sync expanding. Two frequencies available.

PA5 10 WATT ATV POWER MODULE $89 ppd

The PA5 will put out 10 watts RMS power on the sync tips when driven with 80 mw by the TXA5 exciter. 50 ohms in and out, plus bandwidth for the whole band with good linearity for color and sound. Requires 13.8 vdc regulated @ 3 amps.



FMA5 AUDIO SUBCARRIER GENERATOR .... $29 ppd

Puts audio on with your camera video just as broadcast TV does at 4.5 mHz. Puts out up to 1 v p-p to drive the TXA5 or VM 2, 3, or 4 modulators. Requires low Z mic (150 to 600 ohms), and +12 to 18 vdc @ 25 ma. Works with any xmtr with 5 mHz video bandwidth.

TVC-2 ATV DOWNCONVERTER....$55 ppd

Stripline MRF901 (1.7 db NF) preamp and double balanced mixer module digs out the weak ones but resists intermods and overload. Connects between uhf antenna and TV set tuned to channel 2 or 3. Varicap tunes 420 to 450 mHz. Requires +12 to 18 vdc @ 20 ma. Super sensitive TVC-2L with NE64535 preamp (9db NF) stage $69 ppd

Tom W6ORG Maryann WB6YSS

gram waits, continually sampling for an input. Once a sample is taken, the program must check to see if the figures or the letters code has been transmitted. Those codes are used to set lower- or uppercase letters or figures, for those characters to follow.

Now let's take a look at the program listing.

26-Statement BASIC Program

As shown in Fig. 5, the program is short—26 steps. It is probably possible to shorten it somewhat by combining some statements.

Statements 10 through 55 initialize constants and set the string variables with index numbers in two tables. Those indexed variables represent the letters and figures that can be printed by a Teletype™ machine. Statement 100 is used to continually sample for a start bit. Once one is detected, statements 110 through 160 sample a five-bit code. Statements 170 through 200 determine letters or figures states. For a TRS-80 Level II with 16K, statement pairs 120, 125 or 130, 135 will cause a delay of about 22 ms. Some adjustment may be necessary from machine to machine.

To summarize, let's suppose the letter Y is to be received. The program is started and waits at statement 100 for a space or start bit. Suppose one is received as at B in Fig. 2. The program then delays about 8 ms at statement 115 and then samples at 16, 8, 4, 2, and 1. With the code Y, a space is received at 8 and 2. That totals 10 and is used as the index to A$(10) so that Y may be printed on the screen.

73 and we hope you enjoy listening to RTTY.■

NEW PRODUCTS FROM HAL-TRONIX

2304 MHz DOWNCONVERTERS

Frequency Range 2000–2500 MHz

2304 Model 1: Basic three-stage, less case and connectors **$49.95**

2304 Model 2: Three-stage, includes preamp, with die-cast case and connectors **$59.95**

2304 Model 3: With high-gain preamp, die-cast case and connectors **$69.95**

The above models complete with high-quality drilled PC boards, all electronic components, etc., with 15-page manual.

Note: Any of the above, factory wired, $50 additional

POWER SUPPLIES FOR THE DOWNCONVERTERS:

Power supply kit #1, less case and connectors **$19.95**

Power supply kit #2, includes case & connectors **$24.95**

Power supply—already built, complete **$34.95**

PARTS FOR THE NTSC RF MODULATOR FOR CHANNELS 3, 4, or 5. This is **not** a complete kit. The hard-to-get parts include the LM-1889, the .08 microhenry tank coil, the 7-14 microhenry adjustable coil, the 10 microhenry RF coil, with schematic (no PC board) as used in Bob Cooper's satellite TV receiver. Real buy at **$5.95**

TOUCHTONE DECODER KITS

HAL 567-12: single line in, 12 lines out, complete with 2-sided plated-through G-10 board and all components. Uses seven 567's and three 7402's **$39.95**

HAL 567-16: single line in, 16 lines out, complete with 2-sided plated-through G-10 board and all components; includes 22-pin edge connector. Uses eight 567's and four 7402's. (See construction article in April 1981 Radio & Electronics for complete writeup.) **$69.95**

TOUCHTONE ENCODER KITS

HAL ECD-12: 3 x 4 twelve-character encoder utilizing the ICM 7206 Intersil chip. Kit comes complete with both LED and audio-coupled outputs (speaker included). With aluminum anodized case **$29.95**

HAL ECD-16: 4 x 4 sixteen-character encoder utilizing the ICM 7206 Intersil chip. Kit comes complete with LED and audio-coupled outputs (speaker included). With aluminum anodized case **$39.95**

The RTTY/Tribander Marriage

—enjoy the 100% duty cycle

It seems that almost all electronic gear today is rated in terms of a duty cycle, which simply means how long or how hard it can work without resting and cooling off. In the days of AM when all transmitters and rf amplifiers were expected to operate under full power for long periods of time, we didn't give much thought to a duty cycle. True, perhaps some of the cheaper gear should have had such ratings because, as we all know, heat is the archenemy of electronic components, and much of the more lightly built stuff had frequent component failures.

Today, however, duty cycle is a big thing. Our gear is tiny indeed when compared to yesteryear's. Miniaturization is the thing. Solid-state technology has pygmytized those old boat anchors into neat little packages hardly larger than yesterday's external vfos. It has given us features few dreamed of twenty or thirty years ago when the names Johnson, B & W, Hallicrafters, and Collins, among others, were the respected leaders in manufacturing amateur radio equipment.

In many cases, these little runts even give us far more power output than their ancient counterparts. But there is one marked difference: They can't do it continuously.

And this duty cycle thing isn't limited to exciters and amplifiers. Many antennas also have duty-cycle ratings, although I can't recall any manufacturer saying so in black and white. Instead, they use terms like "...rated for full legal amateur power limit" or "...rated at 2-kW (or 4-kW) PEP."

Well, this sounds impressive, but when a body strips it down to its basics, it really doesn't say anything worthwhile. In the first place, PEP refers to SSB *input* power, not *output*. Some loosely apply the term PEP when talking about CW, which is neither here nor there. The power we should be concerned with—as long as we don't exceed the legal input limits—is that which runs up the feedline and makes a noise on the air. And believe me, this is always a whole lot less than what we're stuffing *into* the final!

Of course, manufacturers' power ratings usually apply to trapped antennas. But let's take the old familiar yagi tribander. I think almost anyone reading this will agree that these are by far the most popular HF antennas in the world and, with a very few exceptions, all have traps of varying design. They usually aren't as efficient on any one band as a monobander, but they serve well and allow flexibility with minimum expense and hassle, and we've been getting along with them for a long, long time.

And their physical designs have changed over the years. These new ones have sleek, compact trap assemblies with the coils enclosed in aluminum tubing, away from the elements and offering much less wind resistance than those old external coils we used to see. One of the main reasons they can do this is because AM on the ham bands is a thing to be discussed with nostalgia. Hardly anyone ever throws a kilowatt of plate-modulated power on the air any more, so the traps don't have to be so massive.

SSB and CW are intermittent, right? Therefore, the traps aren't called upon to perform under sustained high rf voltages, so now they can be made of aluminum wire-wrapped on injection-molded plastic coil forms and sealed inside aluminum housings. Neat. Very neat and efficient.

It has been said by wise men that about the only thing in this old world which remains constant is change. It's called progress, and thank goodness for it. But progress is not achieved totally without difficulties, as we shall see.

Amateur radioteletype and amateur television have been around for quite some time, but not until the last couple of years have they enjoyed much widespread popularity. Now, with the rapid advancements in solid-state technology bringing microprocessors and home computers within reach of the modestly-heeled amateur, one has only to tune across the bands and listen to the *deedle-deedle* of RTTY or the musical whirring of an SSTV rig to realize just how many hams have turned to these "new" and fascinating modes of communication. And interest is growing daily, judging by the number of manufacturers who advertise sophisticated RTTY and SSTV equipment in the pages of radio amateur magazines.

However, there begins to emerge a new problem. RTTY and SSTV have little in common with SSB or CW. Rather, they are first cousins to FM. To transmit in either mode demands that a steady carrier be placed on the air, and therein lies a problem which is causing growing concern among the

manufacturers of multiband trapped antennas. Therein also lies the reason for this article. I hope that in sharing my own experience with fellow amateurs, I might help in some way to minimize, or even in some instances eliminate, upcoming problems. On the other hand, it is not my intention to single out any one manufacturer and add insult to injury by naming a product because, from what I have been told by manufacturers and amateurs alike, more than one manufacturer is hunting a solution.

In my own case, in March of 1979 I bought and installed a three-element triband beam made by one of the oldest and most respected manufacturers in the business, and it performed better than expected. Much of my operating time is spent on 20-meter RTTY, however, and a great deal of that is spent in running pictures. This is a blast, as any pix enthusiast will tell you. It is astounding to see the skill and ingenuity that has gone into the making of some of these and a thrill to watch one taking shape on the printer.

There are a few pictures around that take ten minutes or less to send, but there also are hundreds which take up to half an hour or even longer, all requiring a steady, unwavering carrier being fed into the antenna.

It is in this kind of service that the real weakness shows up in our new equipment. Few of today's transceivers are capable of much rf output under steady key-down operation because they are designed for intermittent use. The plate dissipation of the final tubes (or transistors), as well as the limitations of power supplies, must be taken into consideration and not exceeded. I run a Kenwood TS-820S, and the owner's manual plainly states that it is unwise to exceed 100-Watts input to the final in RTTY or SSTV modes; so I don't. But on 20 meters this produces an output of less than 25 Watts. And while this power level will get you by under good band conditions, it becomes pretty puny while trying to run a picture on 20 during crowded weekends. So the next thing, naturally, is to run an amplifier.

But even here there are limitations. First, many amplifiers, such as Heath's SB-220, should be allowed to cool after 10 minutes operation at 1 kW. They tell you so. But then, how many exciters are there around that will drive it to a full gallon? Not many, for they take lots of drive—on the order of 50 to 100 Watts, which means *output* from the exciter. So, in the case of the SB-220, you get about ten times the power out that goes in, or, typically, 250 Watts out with 20 or so Watts drive, which doesn't strain anything very much and is adequate for most RTTY or SSTV work.

Then another problem rears its ugly head. The summer of 1980 was a particularly warm one, and one day my swr rose far above the usual 1.2:1 at around 14.090. This was after I had again become the owner of a 1957-vintage Johnson Viking Kilowatt, the one that is contained in a beautiful gray steel desk. I had owned this very same rig between 1959 and 1965 before selling it to KØJTZ. He trucked it all over the country for 15 years, then moved back here and resold it to me. Since this jewel requires so very little drive, it is the ideal amplifier for RTTY and SSTV. Ten Watts will drive it to 2-kW PEP, so one can see how little strain there is on the TS-820S.

Well, I had been using this Johnson for about a week when my swr began to climb. True, there had been times when, in order to get a RTTY picture through heavy QRM on 20, I had run the power up near a kW, which put about 600 Watts into the beam. This was the beam's undoing, for one glance at it showed the 3-foot section outboard of the trap on the driven element was sagging about two inches. This was on just one end. Obviously, something had melted inside the trap.

Fortunately, it is no big hassle to climb the tower and remove the driven element, letting it down with a rope. And when I got it down and the trap disassembled, I found the plastic coil form melted like butter.

This beam has two coils inside the trap assembly. The inboard coil is the ten-meter trap while the outboard is for fifteen meters. Together, they form the 20-meter trap. It was the fifteen-meter trap that had melted, and inspection of the other trap showed it had split slightly and shrunk 3/16" in length, indicating imminent failure.

A letter and an order to the factory for new fifteen-meter traps brought a telephone call from the manufacturer. He was very nice and understandably very concerned. He said this certainly was not the first trap failure in his product, that it had been going on for well over a year and was due to RTTY and SSTV operation. He added that other manufacturers also were plagued with the same problem and all were trying to find a solution.

"These antennas have a duty cycle," he said. "They were never meant to take a steady carrier for long periods of time. The heat generated in the trap coils has no place to go, so the plastic melts. Power level is not the problem. It's a matter of duty cycle. No matter if you run high or low power, if you keep running RTTY with that beam, the traps eventually will fail. High power, of course, will do it quicker."

"I didn't see any mention of 'duty cycle' in your ads," I said.

"When the antenna was designed," he answered, "we had SSB and CW in mind, and the traps will handle the legal limit in those modes for years. But we didn't anticipate the sudden popularity of RTTY and SSTV."

He went on to say that they had hand-made some coil forms from Teflon™ which gave no signs of failing, but said their molds used for plastic would not accept Teflon, and retooling would be too expensive and run the production costs too high.

"How about drilling ventilation holes in the trap housings?" I asked.

"It would help," he admitted. "But we already have two small drain holes in the bottoms, and insects even find their way inside these. Then, when the rf starts, they can't get out. They become fried, and the resulting carbon buildup eventually shorts out the turns on the coils."

Stumped, that's what I was. Here I had a fairly expensive tribander sitting atop a 50-foot tower, and I wasn't about to give up my RTTY. There had to be a way, I told myself. There just *had* to be!

Having been in aviation more than 40 years, I was aware of the value of air-cooling, so I decided to ventilate the traps. Leaving a 3-inch strip on top of the aluminum housings untouched, I drew lines ¾" apart lengthwise on the rest of the surfaces. Then I marked them every ¾". Alternate lines were stagger-marked so the holes would likewise be staggered diag-

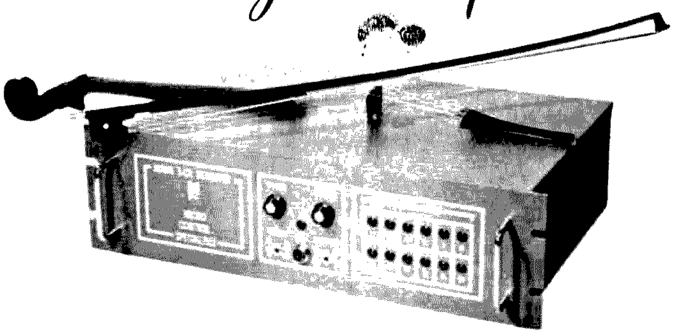
onally and would not structurally weaken the housings. After that, I center-punched each mark and, in three succeeding steps, drilled holes, the last drill being ½" in diameter. When I finished, the aluminum housings closely resembled the barrel housings on those World War I German Spandau machine guns. Each contained 94 holes, which would allow a considerable airflow around the coils.

Following this, using ordinary aluminum screen-door wire, I wrapped each completely, securing it in place with four stainless-steel hose clamps. The idea here was to defeat all but the tiniest of insects, as well as snow and ice, while still allowing warm air from the traps to escape. The screen impairs the flow-through of air, but everything nowadays is a compromise, isn't it? And with no holes on top to allow snow or rain to enter, I felt the coils were reasonably safe from the elements.

At any rate, for the past nine months or so I have been running from 200 to 600 Watts into that beam on RTTY, and during some pretty warm weather, I might add. So yesterday, out of curiosity, I took the element down and inspected the traps. I could find no evidence of cracking or melting, which seems to indicate that the ventilation system is working. This may not be the ultimate answer, but it certainly has to be an improvement for those RTTY and SSTV operators who are using a trapped tri-band beam. They already have their investment in both beam and equipment and, according to a popular manufacturer, are headed for eventual trap failure. So why not take this simple preventive measure? ■

The Sweet Sounding Repeater

MARK 3CR



A Stradivarius is more than a body, neck, and strings. The name alone says it is an instrument of outstanding quality and beautiful sound.

In repeaters the name for optimum performance and clean, natural sound is Mark 3CR. And Mark 3CR also means:

- Receiver sensitivity < 0.25 uV.
- Schmitt trigger squelch to capture fading signals
- 13 Morse messages
- Spurious rejection > 65 dB.
- Autopatch and reverse autopatch
- 15 Function controlled outputs
- Die cast aluminum receiver and transmitter enclosures

For the Finest in

Confessions of a Counter Evolutionary

—part II

Editor's Note: 73 presents the second hall of WA2FPT's "Confessions of a Counter Evolutionary." The August, 1982, issue featured the first half of this comprehensive design. The LSI Computer Systems LS7030 counter chip used in this project is available from Belco Electronics, 43 South 49th Ave., Bellwood IL 60104, for $12.75 plus shipping.

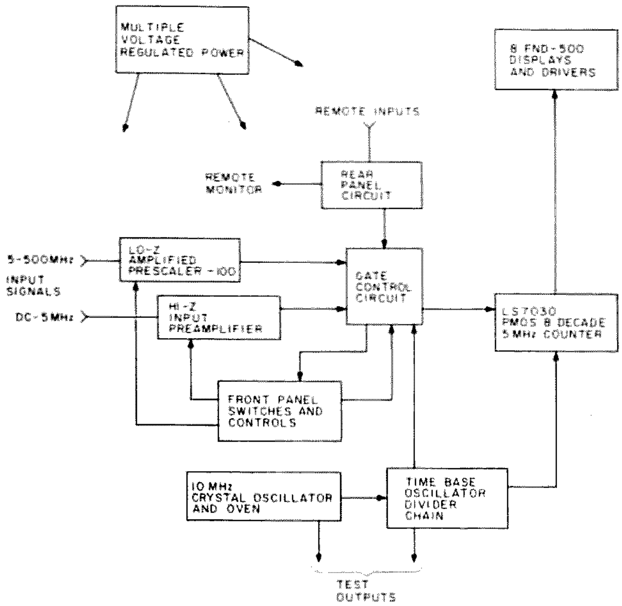

Fig. 1. Block diagram.

Last month we tackled the basic theory of counters and scrutinized the timebase, display, and counting circuitry. We'll finish the job this month. Let's start by looking at the front panel.

There is a conspicuous absence of rotary switches on the front panel. Instead, simple binary counters stepped with momentary-push-button SPDT switches are used with LED indicators to control all counter operations.

There are three such binary "rotary switch eliminators" employed: a four-position circuit for the four timebases (.01, .1, 1, and 10 seconds), a three-position input-display-select button for kHz, MHz, and prescaled MHz, and a mode-select switch for frequency, period, and events. Two additional push-button-switch circuits are enabled when in events mode and the lamp test, which was explained earlier.

The basis for these three counters is the four-position timebase-section counter of Fig. 12. The two 2-input NAND gates form a set-reset flip-flop that debounces the SPDT switch contacts, giving clean, glitch-free pulses to step the binary counter. Notice that the counters, 4013 dual-D flip-flops, are wired as toggles. That is, the outputs alternate low and high with each positive transition of the input clock

pulse. Two such arrangements are cascaded, resulting in a counter with four distinct output combinations. The output sequence of the four consecutive pushes of the timebase select button, taking the Q_1 and Q_2 outputs in pairs, is: 0,0, 1,0, 0,1, and 1,1, where 0 is almost GND and 1 is near +5 volts.

74C02 quad 2-input NOR gates are used as "zero-detecting" decoders to give unique 1 output levels for each of the four pairs of outputs. NOR gates can be used this way because they produce a high output only if all inputs are low. These decoded signals then control the selection and routing of the timebase signals. Fig. 12 shows the four timebases as inputs to the four NAND gates of IC16.

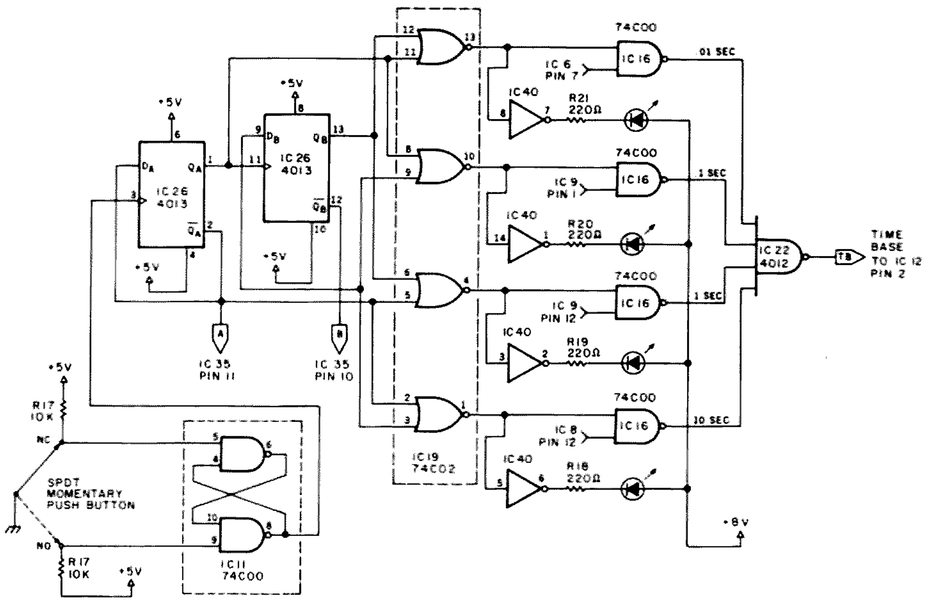

Fig. 12. Timebase select.

The output of each of these NAND gates is regulated by the condition of its control line, the four counter states, only one of which will be active (high) at a time. Therefore, only one of the four NAND gates will be passing pulses, with the remaining three outputs disabled at a high level. As the timebase button is pushed, the counter will step, activating the next control line, gating (enabling) the next corresponding timebase. All four timebases feed a 4012 (IC22) to give a single source of timebase outputs.

This kind of arrangement amounts to a 4-to-1 multiplexer, but I didn't have the one chip package available to do the job, a 4052.

Four jumbo LED front-panel indicator lights show which timebase is active. The control lines from IC19 accomplish this by turning on gates of IC40, a 75492 LED driver. Series resistors limit the current for the LED's safety. Since I ran the LEDs on 8 volts, I used quarter-Watt, 220-Ohm resistors that let about 30 mA flow through the LEDs.

All the resistors are mounted in DIP component carriers occupying sockets on the main wire-wrapped board. I'll admit this was an unnecessary extravagance, but they were a gift to my parts cabinet, so I used them.

The chosen timebase signal emerges from pin 1 of IC22 and goes to IC12, pin 2, the 74C157, where it is selected, or not, for frequency, or else disconnected for the other functions.

The input-display-select switch selects kHz or MHz readout of the displays. The third position, prescaled MHz, routes only signals from the 500-MHz amplified prescaler to the 7030 counter, again with the proper display.

Because only three positions are required, the basic four-position counter is modified to reset to the first position after stepping past the third state. This is done by using the output of the NOR gate decoding the fourth position of the counter to reset the counter to 0 by taking advantage of the 4013's direct (asynchronous) reset input. Whenever those inputs (pins 4 and 10 for both halves of a 4013) are brought high, the flip-flops set their Q outputs to 0, regardless of any other interval activity. The basic scheme in Fig. 13 is thus the same as in Fig. 12.

As explained before, IC11 is a set-reset flip-flop; IC33, a 4013, is the counter; the state decoders are a 74C02; and the display LEDs are driven from 75492 gates. Notice the labels on the 74C02 output lines—they are all important in controlling the various counter functions and we'll see more of them later.

The mode-select switch shown in Fig. 14 is a mirror image of the input-display select. The modes, as you probably have surmised by now, are frequency, period, and events. The period control line, labeled P, serves as the select line for IC12, the 74C157 that interchanges the period and the timebase.

The E line (for Events) has a little more work to do, however. Recall that our events totalizing needs the reset and load signals withheld from the 7030. What is required is a circuit that, upon user demand, will allow manual loading and resetting, but will default to the automatic supply of reset and load pulses to the 7030 chip as needed in period and frequency operation. The E line is the key to such control in this counter.

There are two front-panel push-buttons named display start-stop and count-reset that drive the circuit in Fig. 15. IC28 debounces both, and IC37 provides push-on, push-off toggling action. That is, each Q output from IC37 is latched at alternating 0s and 1s by the configuration shown. In effect, each is a single-pole, double-throw switch. The first push can set the flip-flop (output high), and the next push would reset it. Notice how the E line, inverted through a gate of IC24, only enables these flip-flops when in the events mode. Otherwise, the flip-flops are always set.

The direct reset or clear inputs are wired through two SPDT-switched rear-panel RCA phono jacks. This gives some external device a chance to reset and load the counter, if desired.

Remember the RC networks used to provide reset and load pulses? Well, each of these enters a separate AND gate, whose outputs finally go to the 7030 reset

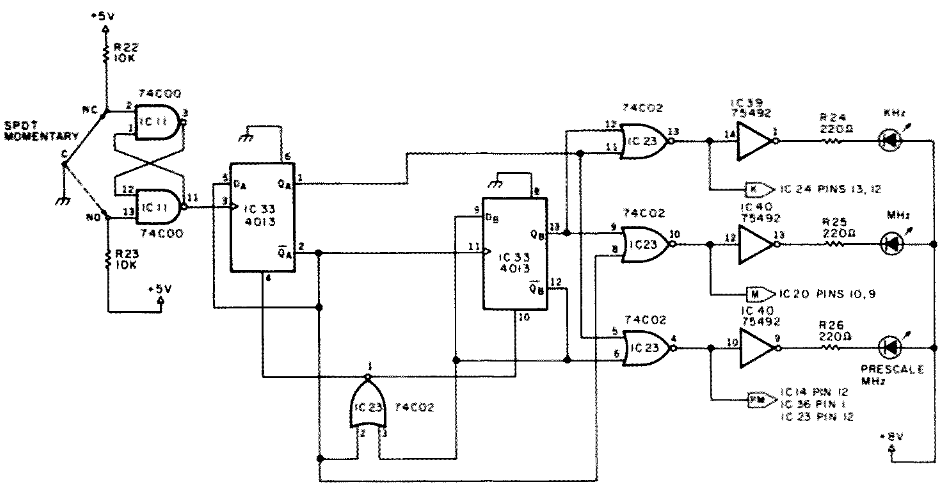

Fig. 13. Input display select.

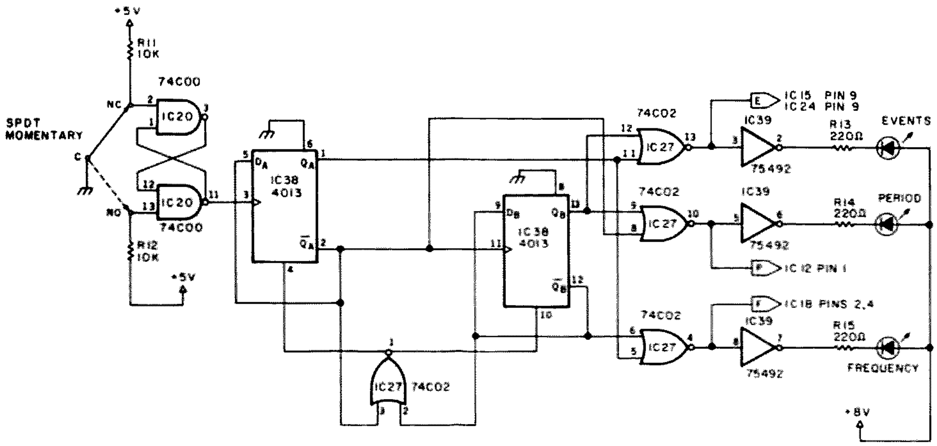

Fig. 14. Mode selection.

(pin 22) and load (pin 21) inputs. The AND gate also squares up the exponentially-rising input pulses nicely.

The utility and simplicity of the reset and load functions should relieve any misgiving you might harbor concerning the slight circuit complexity. As long as frequency or period mode is selected, IC37 remains set and the two AND gates of IC18 shown are always allowing the load and reset pulses to pass through to the counter.

When events mode is selected, the **E** line goes high, and the gate synchronizing flip-flop of IC13 is set via pin 4. IC15, pin 9 also is tied to the **E** line, preventing normal reset pulses. Simultaneously, the two halves of IC37 are enabled, and the display start-stop and count-reset push-buttons are active. IC18, pins 10 and 13 will not now pulse, because no pulse will reach either of the load or reset RC networks. See Fig. 11(a). Accordingly, the push-buttons so described will have complete and total control over the machine's resets and loads.

In the events mode, the display will be rippling with input counts, be static, or display zero. If it is rippling, the display start-stop is always delivering a load to the counter, and the count-reset button is telling the counter to count! (That is, *not* reset.) A push of the display start-stop button will freeze the display (no more load), but the 7030 still will be counting internally. Another touch of the DSS button will again provide a continuous display of the incoming events. As soon as the C-R button is pushed, the counter will reset internal circuits to zero. In order to view this zero, the DDS must be active; otherwise, the previous reading will be seen.

Making the internal 7030 counter controls separate from the display allows complete flexibility for elapsed-time operation and data-acquisition applications. The remote-control option multiplies the value of this feature.

Decimal Pointers

The decimal point changes positions, as you would expect, with kHz or MHz selection, and with the selection of each of the four timebases. It also offsets two places to the right to indicate proper MHz when the divide-by-100 decimal point also becomes visible only in frequency mode, because the period displays in microseconds and the events mode doesn't need it.

There was a good reason to save the description of the decimal-point circuitry until now, because its design is wholly dependent on two characteristics of this counter: the multiplexed display and the binary counters used in the function switching.

From the 7030 data sheet, I learned that in order to illuminate, for example, the decimal point in the fifth digit, the digit 5 strobe would have to be routed to both the decimal point input at pin 10 of the 7030 (to unblank the display) and to a suitable decimal point driver (a 75491). Four different timebases with the three different frequency representations give twelve switching combinations.

This challenge (for me, anyway) was simplified considerably by using two CMOS multiplexer chips, the now-familiar 74C157 quad 2-to-1, and the 74C151 8-to-1 multiplexer. If you have never played with multiplexer chips, you'll be in for a pleasant surprise when you see how this and similar switching problems are solved.

The four timebases are 10, 1, 0.1, and 0.01 seconds. For a proper readout in MHz, the decimal points to be activated must be the 8, 7, 6, and 5 digit strobes, respectively. A kHz readout requires digit strobes 5, 4, 3, and 2. The prescaled MHz display needs the strobe pulses for digits 6, 5, 4, and 3 for the different timebase.

Most of the work is handled by the 74C151. Eight

digit strobes: 8, 7, 6, 5, 5 (again), 4, 3, and 2, are selected by a 3-bit address called C, B, and A. The high order bit is C. Using the input-display-select line, this is 0 for kHz and 1 for MHz (really *not* kHz). The B and A digits are the timebase-select outputs (Q_1 and Q_2) of the 4013 flip-flops.

The prescaled MHz decimal point placement requires a modified input of the digit strobes for the MHz section of the 74C151. Here the 74C157 is used to select either strobes 8, 7, 6, and 5, for normal MHz, or 6, 5, 4, and 3, for the prescaled MHz display. As you might guess, the PM (Prescaled MHz) control line, when active, selects the B-side strobes.

The complete decimal point circuit is shown in Fig. 16. The four high-order strobes to the 74C151 are selected by the 74C157, with the lowest group of four appearing as direct inputs for the kilohertz presentation.

As the 74C151 is addressed by the two output bits from the timebase select counter, the chosen digit strobe is sent out via the Y output (pin 5) to the data input of IC31, a 4013 flip-flop. IC35 can also be enabled by a separate strobe line itself, but here the outputs are always enabled by grounding pin 7. At IC31, the selected digit strobe is clocked by a 100-kHz signal through the AND gate of IC18, enabled by control line F (Frequency mode). The Q output sends the strobe, as mentioned earlier, to the 7030 decimal-point input at pin 10, and to the 75491 driver to the decimal point segments of the display. The leftover portion of IC22 is shown wired as an inverter to take the blank signal from the 7030 (pin 11) and properly reset IC3, preventing possible display damage. The 100-kHz clocking signal is more than adequate to accurately follow the 1-kHz scanning rate.

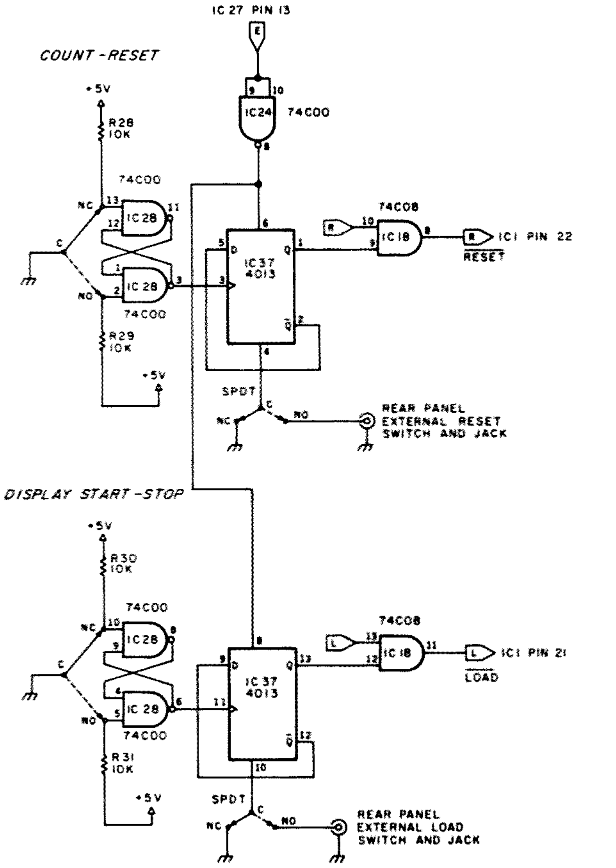

Fig. 15. Count-reset and display start-stop.

Another feature is that leading zero blanking is automatic when the decimal point is not used.

It might be helpful to remember that the digit strobe selection given here is for right-hand decimal-point displays. Left-hand decimal-point displays would use strobes 1-7 and 2-8.

Front Ends and Odds

The input-signal conditioner, so well-loved and remembered from Elementary Counting, is manifested in a Hi-Z dc 5-MHz preamp, and a 5-500+-MHz Lo-Z divide-by-100 prescaler amplifier.

The Hi-Z unit (see Fig. 17) also was borrowed from WA1UFE's fine counter article in the December, 1976, *73 Magazine*. The only change I made was to omit the 68-pF silver mica capacitor shunting the 100k input resistor. Since the preamp is used only to 5 MHz, or so, this "speed-up cap" was not needed. Besides, I didn't have one in my junk box!

The same fine performance noted by WA1UFE still holds for my rendition of this excellent design. I do have something to contribute, however. An easy PC-board layout using tape is shown in Fig. 18(a), full-sized, with foil and component sides illustrated.

The Lo-Z 5-500-MHz preamp is also easily done with the "tape 'n etch" method of PC-board fabrication. Fig. 20(a) gives the pattern for the board layout, while Fig. 19 shows the schematic. The basic design is from K4GOK, with some later embellishments by K4JIU in the February, 1978, issue of *Ham Radio*. My sole contribution, aside from the PC board, is the 39-Ohm emitter resistor in place of the earlier 47-Ohm one. This increases the current through the 2N5179 and lowers the input impedance a bit, but significantly improves the low end (5-10 MHz) sensitivity.

The 11C90 ECL prescaler is no longer a stranger to experimenters, so it will not be elaborated on. (See the article by K2OAW in the October, 1976, *73* if you want some good 11C90 information.) Although the 11C90's price has dropped somewhat, I was still nervous, after soldering it in place, to apply power.

The 74196 divides the 11C90's pin 7 divide-by-ten output by 10 again, giving a divide-by-100 output. The output taken is the Q_C output from pin 2 instead of the usual pin 12 Q_D output commonly employed. The frequency is the same from each, but the Q_C output has a 60% duty cycle compared with the 90% Q_D duty cycle. This is done for the benefit of the 7030, which, from its data sheet, prefers as close to a 50% duty cycle as possible. It is only towards the operational limits of any device, including the 7030, that details such as this become important. Experience is a thorough, if humbling, teacher. . .

Both preamp boards are mounted by small right-angle brackets inside a small aluminum minibox (the 3 × 2 × 1¾-inch Bud Z100). UG-290 BNC connectors are used for the inputs, and their bolts hold the preamp box securely. I can't say for certain whether or not these shielding precautions are absolutely required, but there is no false triggering from strong nearby rf energy, either. Small-diameter coax (RG-174/U or similar) is used to bring both boards' outputs to the PC-board edge connector.

These TTL signals are converted into CMOS signals by a neat trick peculiar to CMOS. CMOS inputs are not directly connected to the outputs. Also, inputs can be paralleled for increased fan-in (the maximum number of allowable inputs), and the

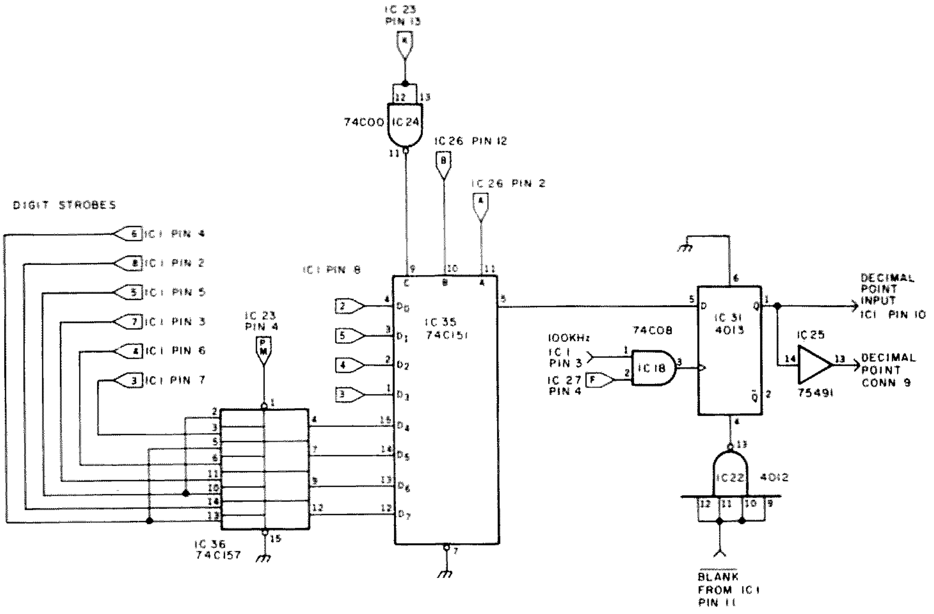

Fig. 16. Decimal point.

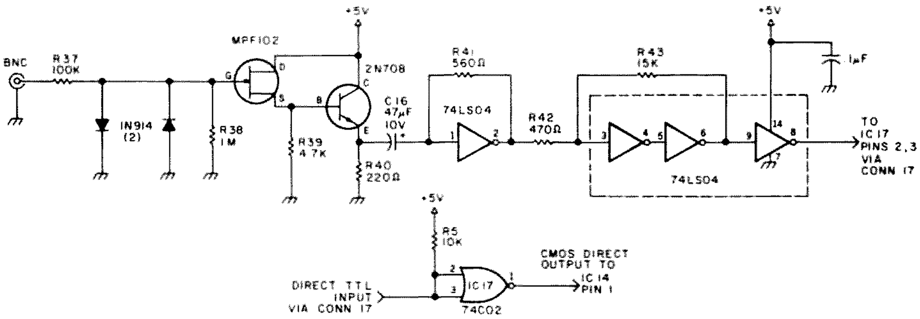

Fig. 17. Hi-Z dc to 5-MHz input preamplifier.

outputs for increased fan-out (the output load-driving capability).

The 74C02, IC17, is an example of how this CMOS quad 2-input NOR is put to work as a TTL-to-CMOS converter. Even though its physical location is on the main wire-wrapped board, it is shown in the front-end schematics of Fig. 17 and Fig. 19.

The output of the Hi-Z unit, a 74LS04 of modest power requirements, is converted to CMOS compatibility by a single NOR gate with two inputs tied together with a 10k-Ohm pull-up resistor to help the TTL 1 output up to a comfortable CMOS level.

Fig. 19 shows the remaining three 2-input NOR gates used to interface the Lo-Z preamp with the CMOS main counter circuitry, with all inputs and outputs in parallel. Try this with something other than CMOS logic! Such an arrangement provides needed buffering for the power-hungry 74196 output transistors.

Sensitivities for the Lo-Z unit are adequate between 5 and 10 MHz, becoming terrific out to the limits of my stone-age rf generator. With graphs and numbers aside, though, it's a real kick to stand 25 feet away from the counter and read those half-inch digits as I key my 1-Watt, 2-meter FM transceiver.

The Hi-Z unit exhibits a usable sensitivity of about 45 mV at the low audio range, down to about 10 mV to its externally imposed 5-MHz limit, as closely as I can determine from basement measurements.

Power Play

Power supplies are usually the most boring part of any project, thanks to the voltage regulator integrated circuit manufacturers. I suppose this machine is no exception, but I did have some surprises during construction.

There are three 3-terminal regulators used, two 7805s and one LM340T-8, as can be seen from Fig. 21. One 7805 (+5 volts) is housed inside the box containing the

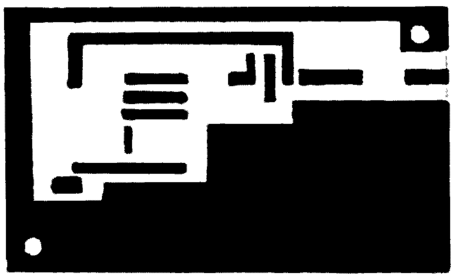

Fig. 18(a). Hi-Z preamp PC layout.

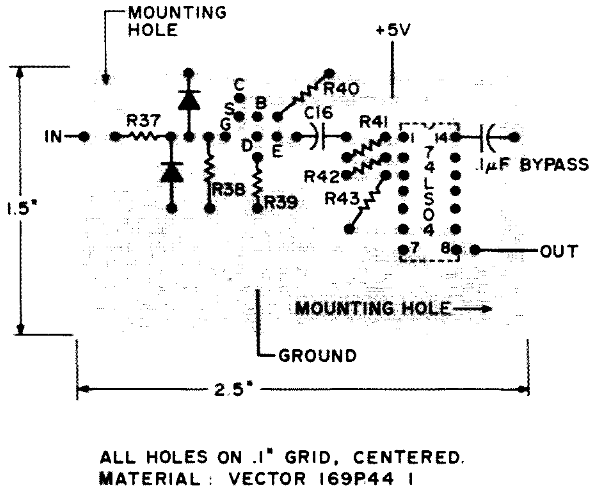

Fig. 18(b). Parts placement for Hi-Z preamp PC layout.

front-end boards, and the TO-220 package is bolted to the aluminum case. Total power drawn for the front end is about 200 mA, most of which is eaten up by the Lo-Z board, as you might imagine, with its 11C90 and 74196.

The entire counter board, with the exception of the 75492s, is powered from the other 7805 and draws a scant 150 mA at 5 MHz. Yet CMOS has the rather nice property of using power only when it switches on or off, and practically zilch when static. Of course, the higher the frequency of switching, the greater the power consumption.

The LED indicators and the FND 500 seven-segment display drivers are driven from the LM340T-8, an 8-volt regulator used to brighten the front panel a bit. Both the 8-volt and 5-volt regulators are heatsinked (sunk?) by being bolted to the L bracket holding the 44-pin edge connector.

Back in the discussion on the master oscillator, the 723 regulator was explained, so I won't subject you to it again! The experience with the crystal oven does merit a few observations, however. The oven draws 750-800 mA at 9 volts. I had originally used a 5-volt LM309K raised by a 1.1k resistor "pedestal" (between the case common and the circuit ground) to 8 + volts. This was all mounted on the master-oscillator board inside the minibox.

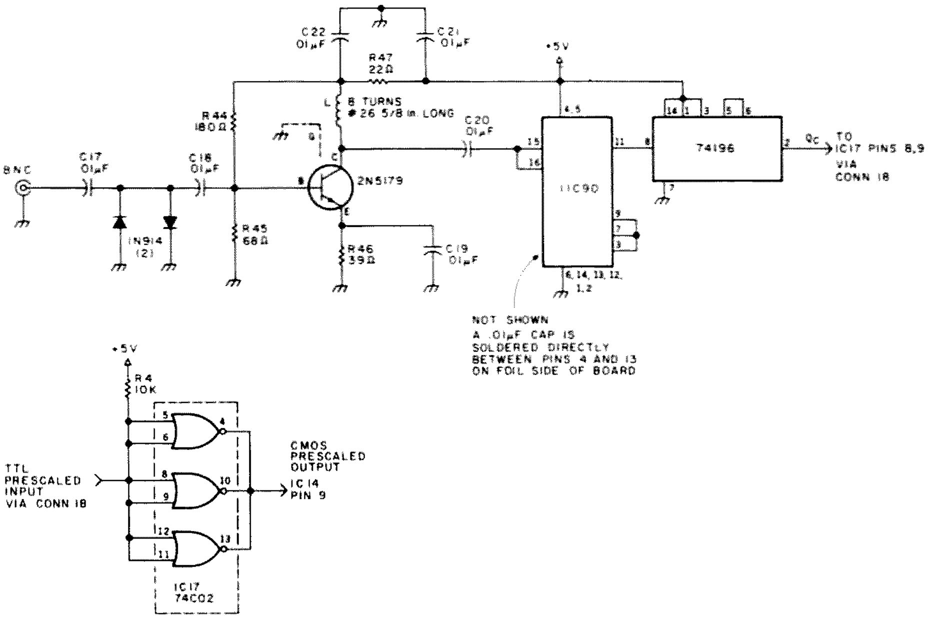

Fig. 19. Lo-Z 5-500-MHz input amplified prescaler (÷100).

Out on the bench in free air, it worked great. Buttoned up, however, the oven would cease to function after a few minutes. After a little careful thought along with my consternation, I figured out that the 309 was entering its thermal-shutdown mode because I had neglected to properly heatsink it. The air circulation in the haywired stage of the design had lulled me into a false confidence that "everything would be cool" once it was inside the minibox.

After ripping this failure out, I solved the whole problem with a single resistor, a capacitor, and Ohm's law. The raw dc from the full-wave rectifier was about 12 volts. Since the oven operates at 9 volts, I needed the value of resistor that would drop about three volts when the oven kicked in.

Ohm's law, assuming a 12-volt supply and a current of 750 mA, gave a 4-Ohm resistor value (3-volt drop = 750 mA × 4 Ohms) to produce the desired 9 volts for the oven. When the oven was off, the unloaded circuit voltage would climb back up to 12 volts, but that didn't matter.

I had a 5-Ohm resistor handy so it was tried, with success, even though the oven voltage was just a little over 8 volts. A 10-Watt resistor hardly gets warm, and a 5-Watt would probably be fine. The capacitor smooths the ripple resulting from the extra load on the transformer when the oven is operating. A front-panel LED turns on with the oven to show when the oven is active.

The 7030, being a good PMOS device, requires a negative bias when interfacing with TTL and CMOS. I used the brute force method of a separate transformer and a half-wave rectified 12-V zener diode to supply it with −12 V. Because only a few mA are drawn, however, virtually any arrangement that will provide a −12-V bias would work here.

At one point during the breadboarding stage, I was using a zener-biased pass-

WORLD TIME WATCH

the first microprocessor watch made especially for hams

24 hr. timer

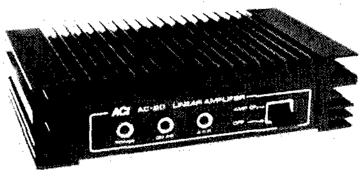
microprocessor water resistant

solar assist

New Low Price —$59.95

The HAM-1 functions include local time, world time, (G.M.T. too) count-up and count down chronometer, day, month, date, alarm and hourly chime. It's ideal for log-keeping, DX time conversion and 10 minute I.D. timing. The HAM-1 features a high contrast Seiko display and solar cell battery assist. Battery life is better than 4 years. The HAM-1 is water resistant to 20 meters, the case is 100% solid stainless steel and the crystal is scratch resistant mineral glass. The HAM-1 is rugged and durable and has a 1 year warranty.

2 METER AMPLIFIER
$39.95



• 2 Watts In, 10 Watts Out • V.S.W.R. Protected • Can be Used for F.M. & S.S.B. • Led Status Indicators • Low Loss SO-239 Connectors • Current Drain Less Than 2.5A at 13.6 V.D.C. • Massive Heatsink • Built In T/R Switch

TEMPO S-1 UPGRADE KITS
$39.95

Upgrade your early Tempo S-1 to current Production Specifications, kits include: • 450 M.A.H. Battery Pack • New Case Assembly • All New Escutcheons • Spkr./Mic. Jack w/Dust Cap • New Earphone & Jack • P.C.B. and Parts for Easy Installation • Detailed Instruction Manual • For Radios With & Without T.T. Pad.

COMPUTERIZED MORSE KEYERS

AEA, the first company to introduce microcomputerized products to the Amateur Radio market, is proud to announce the second generation of computerized electronic keyers. Each keyer is preprogrammed, no computer language is required of the operator. The easy to use keypads eliminate up to 75 switches or potentiometers, thereby greatly simplifying the operation of such sophisticated keying systems. We invite you to compare the features of our keyers (shown below) to ANY others.

IMPORTANT KEYER AND/OR TRAINER FEATURES	AEA MM-2	AEA KT-2	AEA CK-2

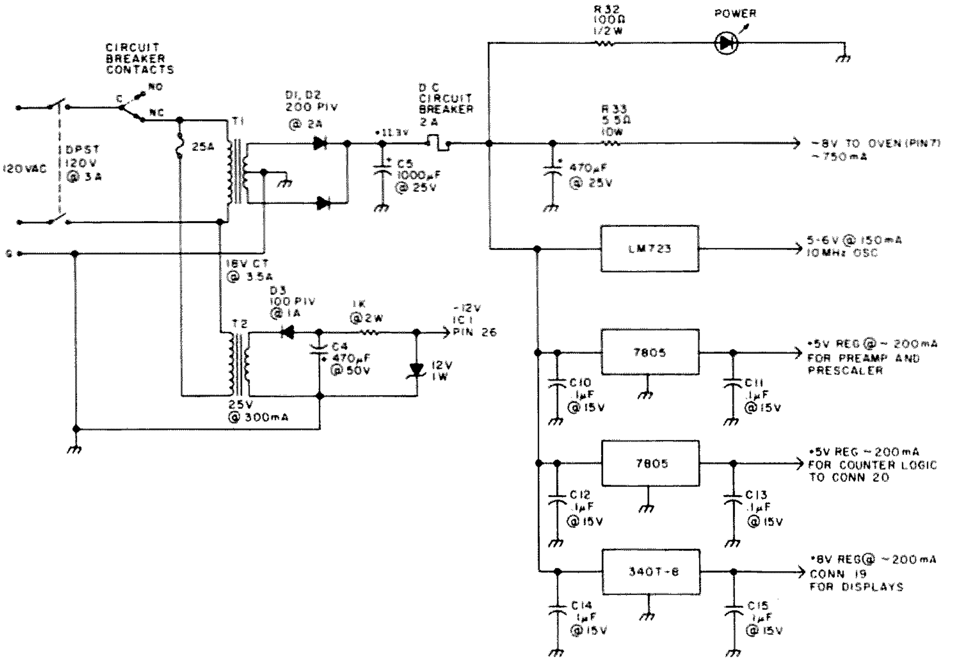

Fig. 21. Power.

transistor arrangement for the negative bias. Suddenly, I noticed the counter behaving erratically, giving some strange readings. After a few minutes of probing around, I was horrified to discover that the pass transistor had shorted and the −12-V nominal bias had soared to −32 volts! This, with the +5-volt positive supply, meant that the 7030 was enduring 37 volts! I was certain the 7030 had counted its last, but it survived, and so did I! In the interest of simplicity, I fell back to the present bias arrangement shown in Fig. 21, and there are no regrets yet.

Besides the ordinary fused primary-transformer-winding protection, I used a 2-Amp dc circuit breaker in series with the 12-volt positive supply. If this CB should trip, the ac line voltage will then drop out through the CB's external switch contacts. A dc circuit breaker is certainly not a necessity, but they can be had in most surplus houses for a dollar or so. I also used a DPDT power switch to completely disconnect the ac from any part of the counter when power is off. Because there are no CMOS inputs normally left floating, potential static damage is not a concern, either.

The power pilot LED is another of those weird yellow jobs that has its attendant 100-Ohm series resistor. It provides a good bright light when connected to the unregulated 12 V dc, as well it should!

All the 3-terminal regulators have 0.1 uF disc caps across the inputs and outputs for noise suppression and for better transient response (so I'm told). As the oven turns on, the raw dc drops to about 10.8 V, still plenty to properly power the various regulators. The main transformer for the positive supply used was one purchased from my friendly neighborhood Radio Shack, the RS273-1514, rated 18 V CT at 3.5 Amps. This is more than adequate, and a similar 2-Amp transformer would be sufficient.

Construction Techniques

Most of this counter is wire-wrapped. Everything but the master oscillator, the power supply, and the two preamps are crammed on a Vector 3662 wire-wrapping board, with the matching 44-pin edge connector mounted on a homemade 1/8-inch aluminum L bracket. There is nothing sacred about using an edge-connected board. A cheaper perfboard would be adequate, but the plug-in board is handy for troubleshooting and easy modification.

The seven-segment displays also are pluggable.

All LED connections are to cathodes. Anodes are tied to +8 V on front panel. All switch commons are grounded on front panel.

Fig. 22(a). Logic-card edge-connector pin designation.

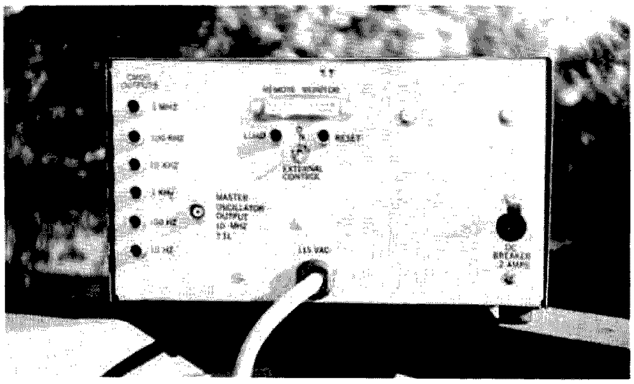

Photo B. The Universal Counter's back panel provides outputs from different points on the timing chain and allows the use of a remote monitor.

Some DIP wire-wrapped sockets were cannibalized, the pieces were spaced on a narrow 6" piece of .1" perfboard, and the eight FND 500s were mounted. The segment pins then were wrapped daisy-chain style in parallel; these seven wires, plus the decimal-point wire and the eight common-cathode wires, form one wiring harness to the 44-pin edge connector. The other harness is composed of the cathodes of the eleven front-panel LEDs (crystal-oven and power-indicator wires are brought out separately) and eleven wires from the six push-button switches (5 SPDT and the SPST lamp-test switch). Other edge connector connections include +8 volts, +5 volts, the 1-MHz signal from the master oscillator board, and the two front-end signals. A ground completes the 44 pins—see Fig. 22(a). The −12-V bias is jumpered directly to pin 26 of the 7030 on the pin side of the board.

Five 16-pin DIP headers (Radio Shack 276-1980) are used to hold the 10k pull-up resistors, the LED current limiting resistors, and the two RC networks—see Fig. 22(b). Once again this is convenient, as these component carriers plug right into 16-pin wire-wrap sockets.

I decided to tap the available source of pulses always present in the oscillator divider chain for an external set of test signals, as shown in Fig. 22(c). Six frequencies, 1 MHz, 100 kHz, 10 kHz, 1 kHz, 100 Hz, and 10 Hz, were buffered with a 4049 hex inverter. A 16-conductor ribbon cable with a DIP socket takes the six signals to some RCA phono jacks mounted on the right rear chassis next to the master oscillator and crystal oven. These output connectors are quite suitable, as CMOS square-wave signals do not generate as many harmonics as do similar-frequency TTL signals, because of the slower rise times. The 10-MHz TTL master oscillator test signal does use a BNC output connector, however. All seven test outputs are dc-coupled by choice.

An EIA RS232C-type 25-pin connector is also on the back, labeled "Remote Monitor." Using the BCD (Binary Coded Decimal) outputs of the 7030 with each digit clocked out by its strobe, the information in the counter is made available to any desired external device that is plugged in. Movable jumpers soldered to the RS232 connector can sample this display information as well as enable the remote control of counter operations. An obvious candidate for such connection would be a microprocessor. If such mating is desired, it would be wise to recall that the sampling rate is equal to the multiplexed-display scan rate (1 kHz for this machine).

A DPDT switch, also on the back panel, selects whether or not the display-start-stop and count-reset 4013, IC37, flip-flop is controlled from the front push-buttons or from another external source via two more RCA phono jacks.

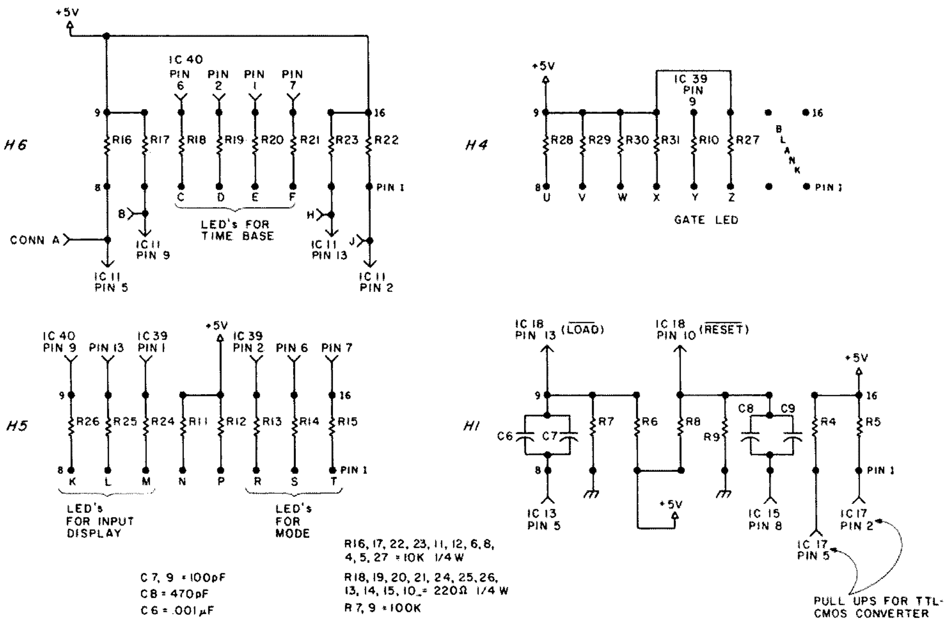

Fig. 22(b). DIP component carriers.

The push-button switches are surplus computer types, bought for $1 each. They are large and bulky, but they "click" nicely. You could use whatever momentary SPDT switches are suitable and/or available.

Radio Shack was the source of the cabinet. Two reinforcing rods made from scrap phenolic are used to stabilize the chassis which becomes a little unsteady after all the components are mounted. It is quite sturdy, though, when the vinyl-clad steel cover is in place.

The jumbo LEDs are mounted in "Clip-lite" holders in ¼-inch holes. These sharp-looking mounting devices are worth every penny. You'll not be sorry if you spend for them. Quest Electronics (PO Box 4430C,

Santa Clara CA 95054) has them, as do a few others. Dry transfer lettering identifies the lights and switches.

Here are a few helpful hints on the wire-wrap board. The 3662 Vectorbord® is 4.5 × 6 inches. The IC sockets, forty in all, densely populate the board. No effort was spared to carefully document and methodically wrap the circuits one section at a time. Four different colors of wirewrap were used: one for power, one for ground, one for all intra-board connections, and the last for board exits to the edge connector. Vector T-44 pins were soldered to the board's edge-connector pads to provide wrap points.

A necessary preliminary step is to make both a pin-side and a socket-view board map showing all socket and IC locations so you'll know which socket you are wiring (see Fig. 23). All power and grounds should be wrapped next. An ohmmeter will quickly spot shorts and opens. The TBOD chain was then wrapped, and the ICs were inserted and then powered up. After proper operation was observed (following a few corrections), the ICs were carefully removed and set aside in conductive foam. Each section was wired and debugged individually before the various control lines were sent to the far reaches of the board. The usual sequence was wire-wrap, IC insertion, smoke test, then debugging for the surviving ICs. The construction sequence I used was switching, display, decimal point, and, of course, the counter circuitry itself.

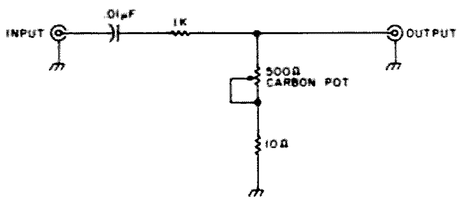

Fig. 24. External Lo-Z attenuator.

This sort of experience points out the extreme flexibility of wire wrapping. In this case, a fairly serious revision costs only some thought and a few wires. A printed-circuit approach would have resulted in at least the abortion of the first board layout, and probably abandonment of the project due to frustration. The other point is that I had breadboarded only a basic frequency-only counter to coarsely check out the basic counter circuits. The abandoned decimal-point circuit was initially conceived solely from a personal interpretation of the 7030 data sheet. Only reality and the actual circuit operations, or lack thereof, provided the necessary guides and corrections to my thinking. The value of breadboarding your first-order attempts can't be overestimated. The old adage, "If it works on a breadboard, it will work anywhere," has been proven many times.

Successful wire-wrapping of larger projects takes some persistence and defenses against paranoia. Persistence to follow through, and resistance to the slightly paranoid feeling that every little 30-AWG wire you miswrap could be the one that causes nights of insomnia and a new vocabulary for those around you.

This is the place where the documentation and organization of your project pay off in steady progression until successful completion, and in the building of confidence in yourself and in your design work. Remembering this can mean that your projects will perform reliably, as you intended, and that they can be fixed when necessary without resorting to a human sacrifice (you!) to appease that ever-lurking god of home-brew, *Nevor Wark!*

The rest of the pieces are best obtained from some of the great variety of small parts sources widely advertised. It is possible to save 30% or more on ICs and sockets, displays, etc., by comparison shopping.

If you are purchasing most of your components new, consider using all 74C90s for the divider chain, as mentioned earlier, since they are cheaper than 4029s and also less expensive to socket.

The counter has no internal attenuator because a useful one would not fit inside the cabinet. The Hi-Z input needs only loose coupling with proper shielding anyway to pick up virtually any signal, because of its sensitivity. The Lo-Z is about 30 Ohms or so at higher operating frequencies and doesn't mind being driven from a 50-Ohm source.

Conclusion

The WA2FPT 7030 Universal Counter is an evolution of this ham's ideas and dreams. Taken by themselves, the various portions of its anatomy are not particularly new or daring. The useful combination of these common design techniques, though, has resulted in a counter that is a joy to use and has flexibility not found in counters at $500 or more.

Don't build this counter if all you want is that bare-bones $100 frequency counter or one of its brothers. Do create one, however, if you want the adventure of incorporating wire-wrapping, top-notch front ends, a voltage-tuned master oscillator, and all the other goodies. Then scrape together the $100-$150 you'll need and jump in. The little touches like the push-button function selection and LED indicators only serve to set this counter apart from all others. It's a small price to pay for a little distinction and some personal fulfillment. You, too, can build yourself as you build your counter. I'd be interested to learn how yours turns out.

It's been great "wrapping" with you! ■

Double Trouble on 50 MHz

—Home-Brew Contest runner-up

Ed. Note: KL7GLK's article was the runner-up in our Home-Brew Contest. Larry will be receiving a $100 bonus in addition to his normal article payment.

Larry Jack KL7GLK

Annapolis MD 21403

"That's *milli*watts," I explained to the Florida station. It's okay, I thought; three of his neighbors had missed the milli part the first time, too, or maybe they just didn't believe it. The truth was that I was just as surprised as I talked to one six-meter station after another on less than one quarter of a Watt. True, the band was hopping with summer E skip, but that didn't diminish my thrill of working QRP DX.

I was using a little double sideband transmitter I'd originally designed for the license-free 49-MHz band. For you fellow Forty-Niners, it works quite well there (reduce the input to 100 mW). It has been heard over 25 miles. When six opens up and the ham in you returns, changing the crystal to 50 MHz is when the fun really begins.

Circuit

The transmitter centers around an active balanced modulator fed by a crystal oscillator. Two stages of linear amplification result in a signal of 250-400 mW with a carrier suppression on the order of 40 dB. I have had mixed results with passive diode ring modulators at 50 MHz. Carrier suppression is tricky. This active design, however, tunes cleanly right from the start and should present no tune-up difficulties.

The oscillator is a particular gem. The credit goes to K1CLL (May, 1970, *73*) for such a trouble-free design. L1 is 15 turns of #30 enamel wire close wound on a 3/8-inch-diameter slug-tuned form. The crystal tap is 5 turns from the collector end of Q1. The oscillator feeds the emitters of the balanced modulator through a resistor network. R1, a 2.5k trimpot, is used to null the carrier. L2 is also a 3/8-inch-diameter slug-tuned coil, but it is center-tapped, 24 turns of #26 enamel wire. L3 is six turns of insulated hookup wire wound over the center portion of L2.

The audio stage that drives the modulator is a salvaged amplifier out of a defunct tape recorder. Any 1-Watt amplifier will work fine. There are so many inexpensive sources of these amplifiers that it does not pay to spend the time building one yourself. T1 is the normal output transformer that once fed a 16-Ohm speaker. If all that is available is an 8-Ohm output transformer, it will work, but it will not give as much drive. A speech clipper using a pair of 1N695 diodes

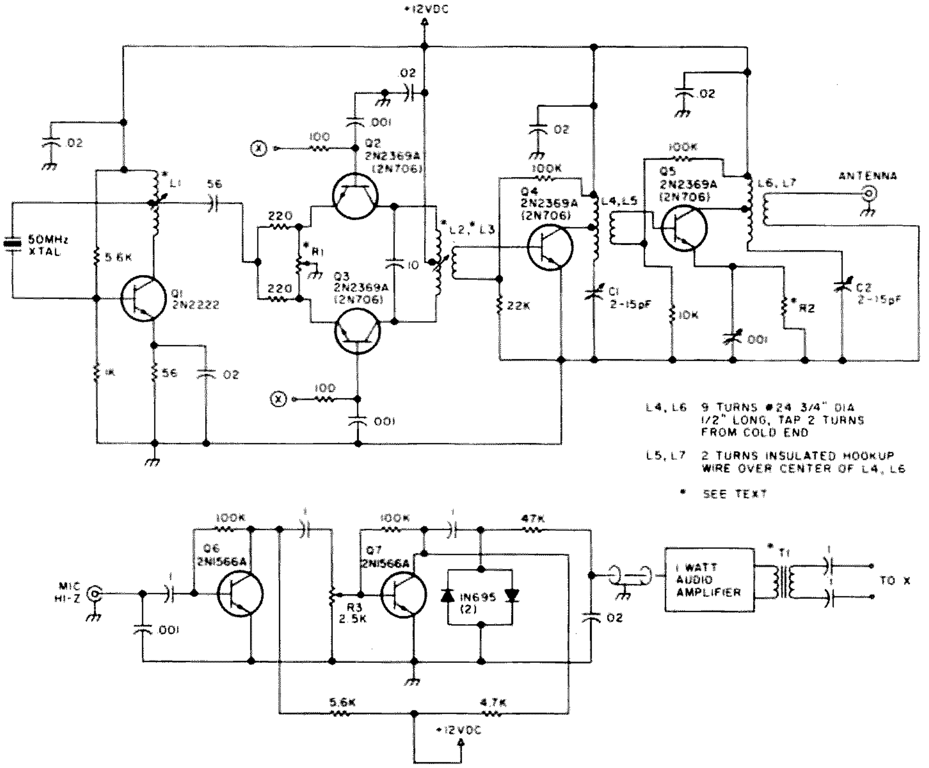

Fig. 1. 50-MHz DSB transmitter.

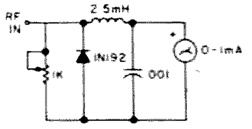

Fig. 2. Field-strength meter.

limits the audio frequency response. This feeds into the input of the audio amplifier. Q4 and 5 are biased as linear amplifiers; depending on the value of R2, the input can vary from a few milliwatts up to 400.

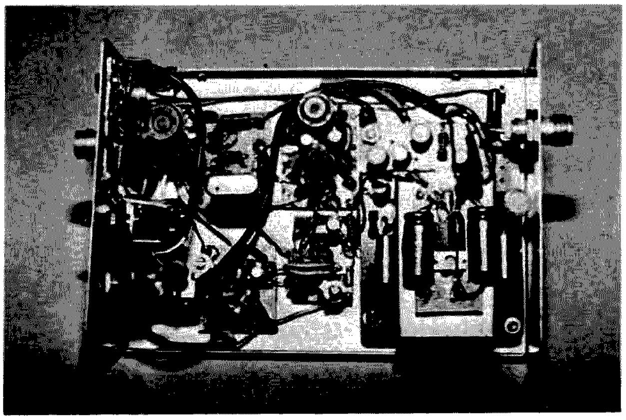
Tune-Up

I have found using a field-strength meter (FSM), Fig. 2, the easiest way to tune up this transmitter. Power is applied to both the oscillator and the balanced modulator, but disconnect the audio stages. Clip the FSM to one side of the emitters of Q2 or 3 and adjust L1 to maximum. Remove the meter and attach it to the base of Q4. Adjust L2 for maximum, then R1 for a minimum reading. It should be possible to achieve a deep null by alternating the tuning of R1 and L2. This will adjust the level of carrier suppression. Remove the FSM and apply power also to the audio stages. With a 50-Ohm ½-Watt resistor as a dummy load and the FSM attached to the output at L7, apply a tone (i.e., whistle into the microphone) and adjust C1 and C2 for maximum.

You're ready to go on the air.

Life On DSB

If you've never operated DSB before, be prepared for some strange signal reports. Most stations will not be able to tell a difference between DSB and the other SSB signals on the band. A few will be confused by that extra sideband . . . Ah, but that only makes things all the more exciting. Wait until the other guy also finds out it's only a quarter Watt of power. You'll have no end of interesting QSOs after that. ■



Six-meter DSB transmitter in a minibox.

Parts List

Transistors

Q1 2N2222 HEP equivalent HEP55
Q2-5 2N2369A (2N706) HEP equivalent HEP50
Transistors came from a "grab-bag" from Poly Paks, Inc., Lynnfield MA. Priced individually from a parts house as HEP equivalents, approx. $1 each.

Crystal

50-MHz 3rd overtone in HC6/U holder
Available from Jan Crystals, PO Box 06017, Fort Myers FL 33906.

Capacitors

C1,2 Johnson air variables 1.7-14.9, miniatures, type T-6-5
Available from Semiconductors Surplus, 2822 North 32 St., Phoenix AZ 85008.
10 pF silver mica
56 pF silver mica
From the same source above.
6 .02 uF ceramic capacitors
General capacitor assortments from Poly Paks or Radio Shack; values from .005 to .01 work fine.
4 .001-uF ceramic capacitors
Same sources as above; values .001-.005 uF work fine.
5 .1-uF ceramic capacitors
Same sources as above; values .01-.1 are suitable.

Resistors

1 56 Ohms
2 100
2 220
1 1k
1 4.7k
2 5.6k
1 10k
1 22k
1 47k
4 100k
All these are 1/8-Watt 10% carbon resistors. From grab-bag assortments from Poly Paks. Available also from Radio Shack.

R1, 3 2.5k miniature trimpots
A-B type F number FR252U is the type used, although any small 2.5k variable resistor will work fine.

Diodes

1N695 SK3087, 1N914, 1N456, HEP 158 will also be suitable; from a grab-bag of diodes, silicon types.

Coils

L1,2,3 Salvaged iron slug-tuned coil; for number of turns, see text. Ramsey Electronics or Digital Research: Parts, PO 401247B, Garland TX 75040. Variable inductors for forms.
L4-7 Free-handed wound coils of #24 copper wire. See text.

Audio Amplifier

1-Watt audio amplifier with a 16-Ohm output transformer. Salvaged from a Radio Shack tape recorder. Any Hi-Z input audio amplifier with an 8-16-Ohm (see text) output transformer of approx. 1-Watt output is suitable (i.e., from a clock radio, portable AM/FM radios—hamfest materials).

Miscellaneous

Cabinet Small 5 × 7 × 3 inch metal box from Radio Shack.
BNC coax connectors
Microphone jack from Radio Shack
DPDT switch (for T/R)
Pilot lamp
PC board
Q6,7 2N 1566A RCA SK equivalent SK 3009

RF tuning meter

M1 Any milli- or microamp meter movement; can also be a multimeter attached to the diode-choke network.
RFC 2.5 mH Any surplus choke in this range; also jumble winding about 200 turns of #30 wire on a high value 2-Watt resistor will work. 2.5 mH choke from Radio Shack.
1N192 Can be any silicon diode. See above sources.

The $100 TVRO Receiver

—Satellite Central, part IX

Ed. Note: Part I of *73*'s "Cheap Trick" $100 satellite TV receiver series appeared in the August, 1982, issue.

Building your first TVRO receiver can be fun if you start with a well-thought-out design such as this dual-conversion model by Dwight (Rex) Rexroad. Despite Cheap Trick's cost, you'll be surprised at the results. The proof is in the picture!

Last month, we covered the simple downconverter box which used cheap components to get the 3.7-to-4.2-GHZ TV satellite signals down to 500 to 1000 MHz i-f. See the diagram in Fig. 1(a). According to Rex, "The conversion gain of the tuner is about 10 dB. The levels into the i-f amp are not unlike those found in other receivers made today."

Photo A. Dwight Rexroad with his $100 receiver.

Clever Construction Technique

Building a home-brew VHF device such as this has its own set of problems. Because this will probably be a one-of-a-kind unit, it doesn't make a lot of sense to sit still long enough to engineer a PC board layout. Likewise, the Vectorbord® point-to-point wiring technique can eat time like a parking meter. So Rex applies a secret used by many VHF experimenters. The entire baseband unit is built on copper-clad perfboard, which is ideal because you put the clad portion on the top and do the wiring on the bottom (see Photo B). Says Rex, "I've got this humongous ground plane there. Anywhere I want to ground, I just stick a wire in a hole and solder." A hole that must allow a wire to pass through is cleared of excess copper with a ¼-inch drill bit operated by hand. This trick not only saves time, but keeps even the most cantankerous VHF circuit from running off on its own. As Rex says, "This is not a critical receiver. You've just got to apply good layout, grounding, and short leads."

Bandpass Filter

Rather than use adjustable coils in his filter (see Fig. 2), Rex chose to use fixed coils and adjustable

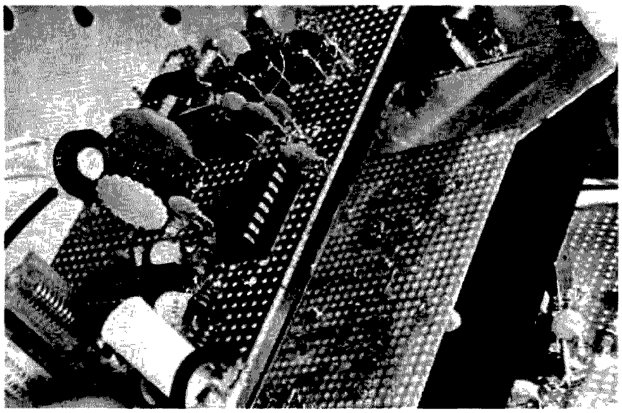

Photo B. Believe it or not, everything is socketed. No problem at 70 MHz as long as you have a large groundplane nearby. The mirror in the photo shows the wiring below the groundplane.

capacitors to save money. For a further saving, Rex suggests you buy the coil assortment sold by Radio Shack and rewind your own. Or you can use the Amidon T-50-6 cores.

Rex comments, "Design-wise, the filter is similar to that by Taylor Howard. Alignment is best done with a sweep generator, because you'll go crazy using anything else. The ideal curve would be flat as a pancake from 55 MHz to 85 MHz. Try to keep it especially flat from 60 to 80 MHz for best results. I'd like to make a nonadjustable filter work. Maybe I'll figure one out with Cheap Trick II."

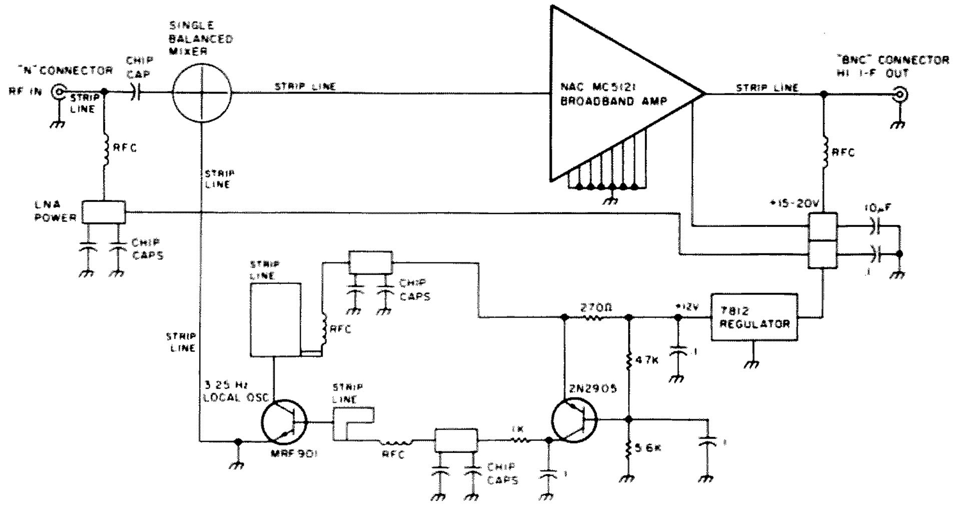

Fig. 1(a). A fixed-frequency local oscillator drives a balanced mixer in the first conversion stage of the Cheap Trick receiver. The MC5121 amplifier drives a modified UHF TV tuner where the signal is downconverted again. This circuitry was described in last month's edition of Satellite Central.

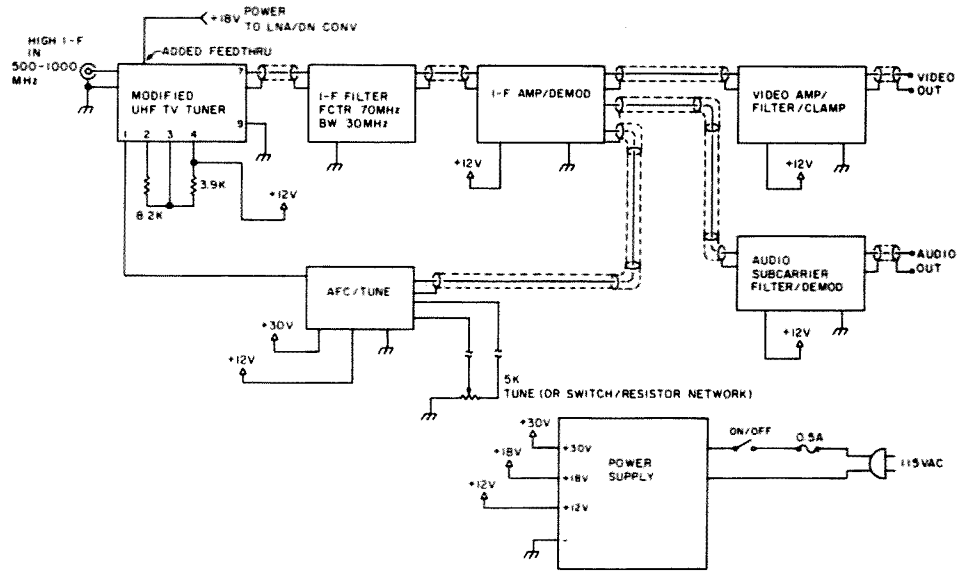

Fig. 1(b). The baseband circuits consist of off-the-shelf ICs.

Get Out of the Mud

Moving on to the 70-MHz i-f amplifier in Fig. 3, we find that Rex did what every TVRO designer should have done in the begining—He used off-the-shelf parts. Here's a perfect example: He used the readily available MC1350. This is the workhorse i-f amplifier used in many TV sets and bootleg subscription-TV decoders built today. With a cost of only $1.38 and easy availability, it's a natural. The input impedance of an MC1350 is more than 1k, so Rex put a 75-Ohm resistor on the input to properly terminate the i-f filter.

"At 70 MHz, the MC1350 has about 20-dB gain in the broadband mode. Of course, they run much better at 45 MHz where you find them in your TV. The MC1350 has both differential inputs and and outputs. One differential input is bypassed to ground. Pin 5 is the i-f gain-control input. Like everything else in this circuit, it is bypassed." Later on, you can feed your agc into this pin. If you were to try your hand at using a 564 PLL detector, you might have to put the control on the front panel since the 564 is level sensitive. On the other hand, using the nifty MC1357 quadrature detector can make the i-f gain a simple "set and forget" operation.

Rex suggests using peaking coils on the differential output because he found an expected gain slope. "It starts around 20 MHz and goes downhill pretty fast. I have a sweep of it running from 10 to 100 MHz. It's a nice diagonal line!" Putting .18-uH coils on the 220-Ohm load resistors will peak the MC1350 on 70 MHz. The 500-pF coupling capacitors are not critical.

The other parts values in the circuit are right out of the Motorola handbook. "I use Amidon slip-on ferrite beads. A bagful of beads is a lot cheaper than a batch of chokes. You don't need large inductance values here, not at 70 MHz. A bag of beads is only a buck, and one sack will do."

The second stage, like the first, uses typical book values. The gain resistor on pin 5 is the current-limiting resistor value for a maximum gain. It's just that simple. Interestingly enough, Rex found that grounding pin 5 on the MC1350 did not produce maximum gain. Instead, it produced less. But start to add some resistance at pin 5 and the gain will rise to maximum at about 5.2k Ohms. The output feeds a broadband transformer wound on still another ferrite bead.

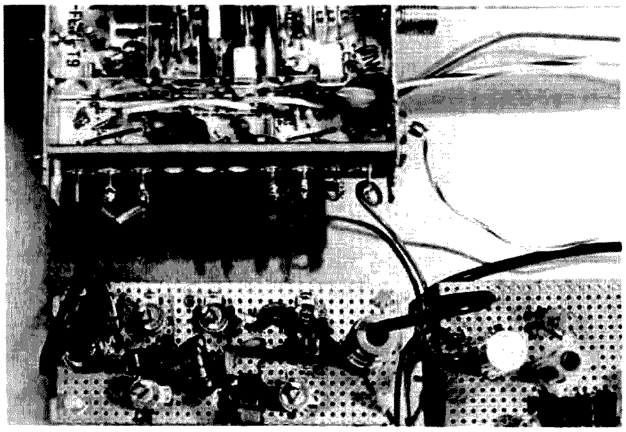

Photo C. You can get away with RCA jacks on the 70-MHz filter, seen below the UHF tuner.

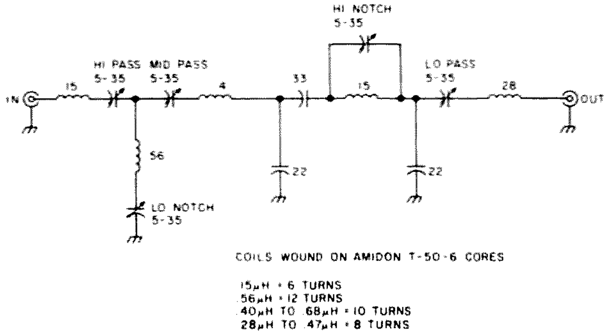

Fig. 2. Diagram of the 70-MHz filter. The circuit uses adjustable capacitors for tuning.

The diodes on the secondary afford an excellent spot to attach a 1-mA carrier meter for antenna aiming, tune-up, an S-meter, or even agc. Here's a typical place where Rex applied excellent engineering technique. Previous designs had used a small capacitor and a series resistor to feed the diodes. A few moments of thought brought Rex to the conclusion that what is really needed is just a single capacitor with about the same series reactance as the resistor. This will allow you to eliminate the resistor (one less part) and get exactly the same results! "I can't help it," says Rex, smiling. "This project must be truly cheap."

Divide the Headache in Half

Back now to the rf transformer. The secondary feeds one half of a 74S112, a divide-by-two circuit which shifts the 70-MHz signal down to 35 MHz where the detector can deal with it better. The 500-Ohm pot was chosen as a good value to make adjustment easy. "Despite the doubters, it works like a charm. The adjustment is not critical. All the pot does is set the bias for the trigger input. Just find a weak signal, and tweak for minimum sparklies. The symmetrical gain limiting in the previous stages (not found in all satellite i-f amplifiers) makes this adjustment very easy."

Perhaps you've noticed that the 74S112 is running from a 12-volt supply. Impossible? Probably. Instead, the voltage-divider combination of the 500-Ohm pot and the 180-Ohm dropping resistor set the Vcc for the chip to about 5 volts. Those of you who handle workhorse ICs such as this know that you can fiddle with the voltage nearly a volt either way and not see any big problems. This technique saves the cost of a zener diode. And the brand of IC doesn't matter. It costs less than a buck. Just be sure to use a 74S112 rather than a 74LS112 which may only make it to 50 MHz.

Some Receivers Look Bad, But Not This One

Gain margin in this system is about 20 dB. If the input level to the divide-by-two circuit changes radically, you will need to readjust the pot. "That's what happens with so many of the typical divide-by-two designs used in receivers today," comments Rex. "If you transport them from one dish/LNA setup to another, you may need to reset the threshold. Still, it's not as critical as a design that uses the 564 PLL.

"The signal level on the output of the 74S112 should be peak-to-peak just under 5 volts. A flip-flop

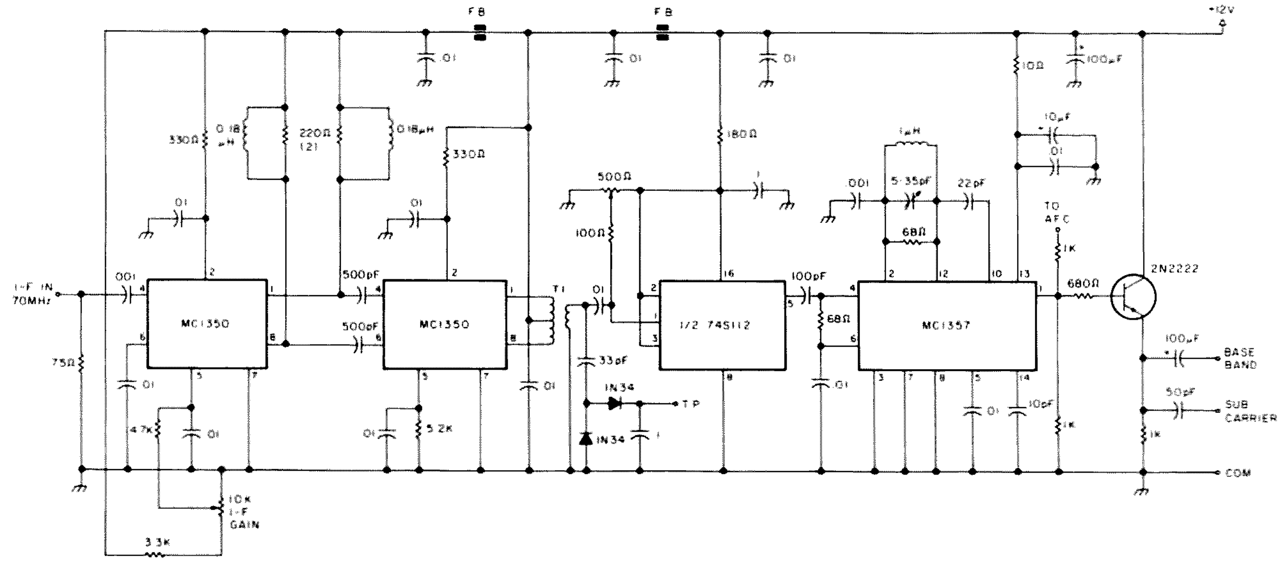

Fig. 3. Bargain-basement ICs highlight this baseband design. The MC1357 quadrature detector produces a better picture than most PLL detectors. T1: pri.—4 trifilar turns; sec.—2 trifilar turns; #28 wire, Amidon 101-43 bead.

running at high speeds usually does that," comments Rex. "Funny thing is, the MC1357 detector that follows has about 40 dB more gain, so we've got to swamp it down on the input with a 68-Ohm resistor. It really doesn't seem to matter much value-wise.

"The input to the MC1357 is differential so we bypass one and use the other. The only critical thing about the detector is that you must use short leads, especially to ground. Pin 5 has a bias de-emphasis capacitor with pin 14 acting as high-frequency de-emphasis. We don't get around to true video de-emphasis until later. The output stage has a tendency to oscillate at deviation extremes. You wouldn't hear it at audio, but you'd see it in video. So I've got that 10-pF cap which rolls us off at the high end just a bit, but not enough to suck out the subcarriers. Use a twisted-wire gimmick if you want." Rex believes you could even forget the cap if you don't mind knowing that your sync tips will look dirty.

Avoid Oscillation

It must be remembered at this point in the description that this is indeed a VHF device. Using little 10-pF caps won't mean a thing if your lead dress is long and sloppy. Chances are it won't work at all. If you do build the unit on perfboard, be sure to keep everything short. A sure sign that lead dress needs attention will be poor high-frequency response. Use plenty of bypasses such as on pin 13 of the MC1357 where parasitics can occur. Interestingly enough, oscillation at this point will likely come from the amp in the chip itself rather than the i-f amps. Like everything else in Cheap Trick, the cost of the MC1357 is less than that of the popular 564 PLL—about $1.50.

The quadrature coil on pins 2 and 12 is very noncritical. Rex comments, "The S curve is wider than the bandwidth we want, so all you'll get if you mistune it is an offset dc output. It could be a problem when you add the afc loop. Another symptom is that the picture will be a little bit washed out. But you'd have to mistune it radically for that to happen!"

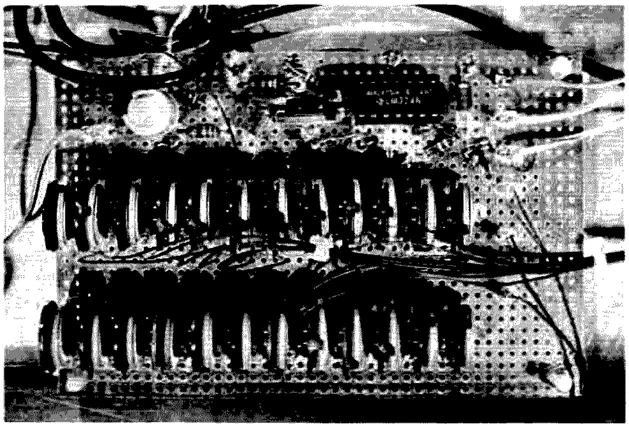

Photo D. Tune like the pros with a rotary switch thanks to a stable design and afc loop. Buy the pots at a swap meet to keep the total receiver cost from inching past $100.

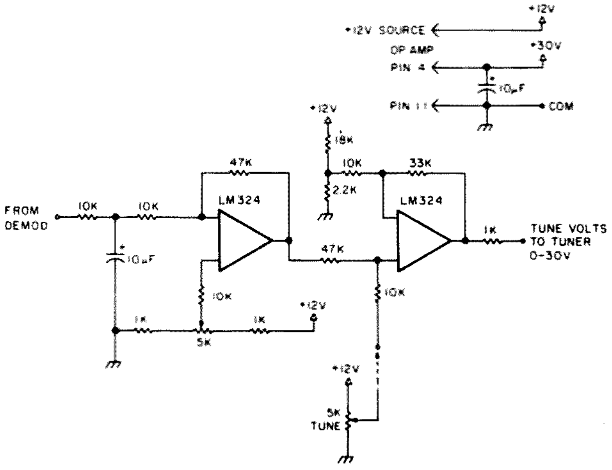

Fig. 4. This simple afc loop circuit samples the detected video offset to control the UHF tuner local oscillator.

The tune/afc circuit in Fig. 4 is simply a feedback loop. Rex filters the video with an RC network. He used an LM324 wired to the single-ended 30-volt supply. A 5k pot on the non-inverting input not only sets the output to zero volts, but compensates for the discovery that the MC1357 detector doesn't always yield an output at exactly half the supply.

The second amp mixes the 5k tuning control with the afc feed to control the UHF tuner. The resistive divider on the inverting input allows the amplifier to develop a zero voltage output which is necessary for the UHF tuner range. The LM324 is one of the few amps that can work at these voltages. And you still have 2 unused amps in the chip which can be for optional metering or agc circuits.

If you find a deal on small 5k pots somewhere, Rex suggests you mount a batch of them on a board as seen in Photo D and feed a rotary switch to get decent tuning. This method works very well thanks to the good stability of the design and positive action of the afc circuit.

Video Magic

The detector output is fed into an emitter follower (a 2N2222 costs 10 cents) where the baseband video feeds a 100-uF capacitor. The sound subcarrier signals are fed from the same point through an RC high-pass filter to the detectors. Moving on to the video circuit in Fig. 5, the 75-Ohm video de-emphasis circuit that follows is unique because it uses fewer parts and does essentially the same thing as commercial designs. More importantly, Rex says, "it uses parts that are closer to standard values than other designs. You can buy all the parts over the counter."

The pi network that follows acts as a low pass to yank out the sound subcarriers and noise. The 75-Ohm resistor that follows acts as a proper termination to ensure that the standard values you use will get the same response. The signal is dc-coupled into a 733 video amplifier which also has a differential input. Because Rex used a single-ended supply, he used a voltage-divider network to feed the inputs. The 10-uF capacitor in the divider is necessary because the signal has a lot of low-frequency components. The 10k pot acts as a gain control and should give you enough control for even half transponder video levels. "The 733's minimum gain is higher than the 592. That's the only difference I can tell," says Rex. "They both cost about a buck. Performance-wise, it's a toss-up. I use the flat-pack versions. You could skip the video polarity switch since a jumper will do."

Getting a Perfect Picture

The clamp circuit re-

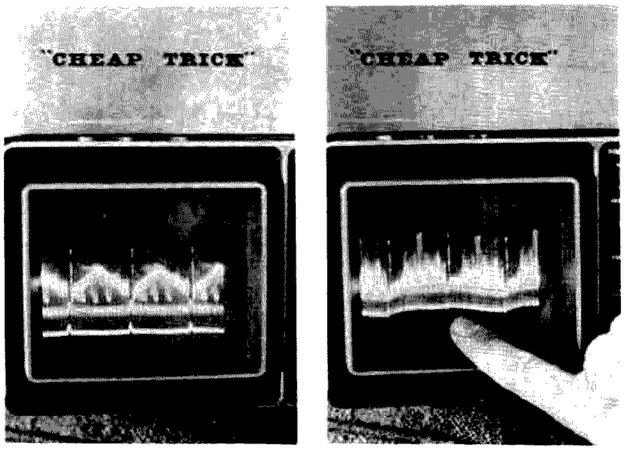

Photo E. Tweaking the clamp-circuit coupling capacitor will reduce picture flicker, but it may also affect the video baseline (seen at right).

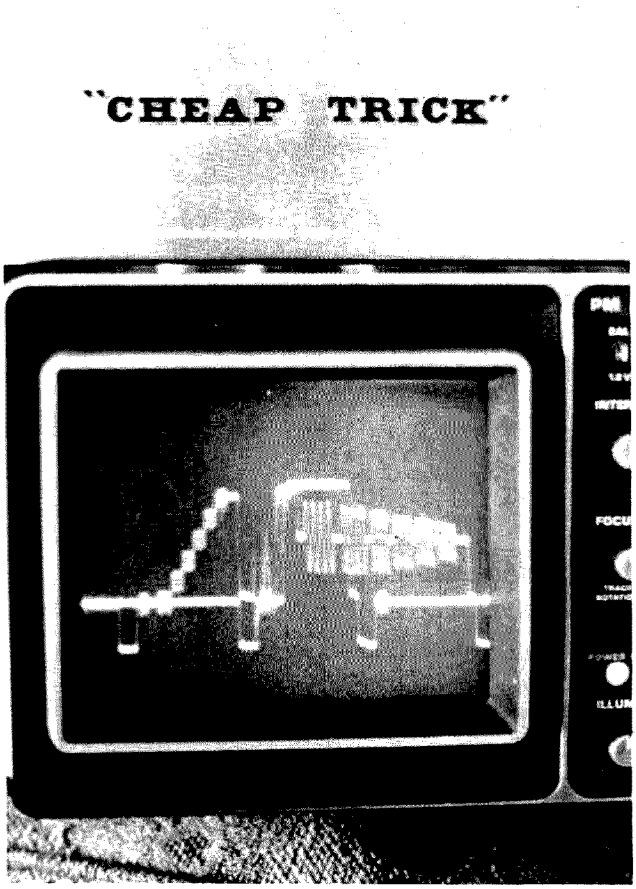

Photo F. The proof is in the pudding. This multiburst display from Satcom 3 shows that the receiver high-frequency response is none too shabby.

moves the frequency-dispersion waveform from the signal. This is a common design used in many receivers today and is described by Lancaster in the *Cheap Video Cookbook*. "It doesn't work perfectly. You can make some trade-offs. If you are getting too much flicker in the picture, you can lower the value of the 1-uF cap feeding the diodes." Rex goes on to say that, "too much reduction in that value will produce a large amount of tilt in the vertical interval." This means the idea is fine unless you want to chase data hidden in the vertical interval later on (see Photo E). Most TV sets don't see the tilt, but a high-speed data comparator will. The last emitter follower has a low output impedance, so a terminating resistor is placed in series. It works well with cable lengths up to 50 feet without ringing. The final output high-frequency response can be verified by looking at the multiburst waveforms in the vertical interval of some transponders. You'll be amazed at the quality of this receiver as seen in Photo F.

The sound demodulator in Fig. 6 is straight out of your typical 4.5-MHz TV set sound section with a clever trick to make it work slightly better and still use cheaper parts! Rex uses input transformers that are the surplus 10.7-MHz i-f types found in cheap portable FM sets. They are retuned to 6.8 MHz, the most often used sound frequency. "A common source is Poly Paks where they cost about 28 cents apiece!" You may find that you'll need to adjust the values of the parallel 56-pF caps from 50 to nearly 120 pF to get the entire range of possible subcarrier frequencies. See Satellite Central VI and VII for more background on subcarriers.

The transformers are wired back to back on the input. The signal feeds the low-impedance winding from the 50-pF cap back into the video demodulator. The circuit then becomes a conventional bandpass with the output low-impedance winding of the second transformer feeding the input to the CA3065 FM quadrature sound demodulator. "This configuration works very nicely since they were designed that way. There are a lot of 4.5- and 10.7-MHz circuits out there using these parts," comments Rex. "The circuit is right out of the handbook. I use the same value of quadrature tuning cap (82 pF) which seems to hold over the band. I was just too cheap to use a coil in the

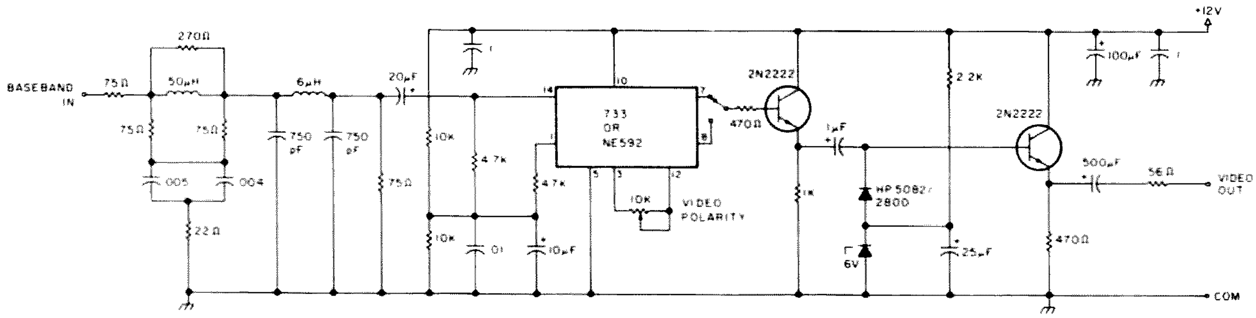

Fig. 5. Easy video processing with a standard component low-pass filter, clamp circuit, and video DA.

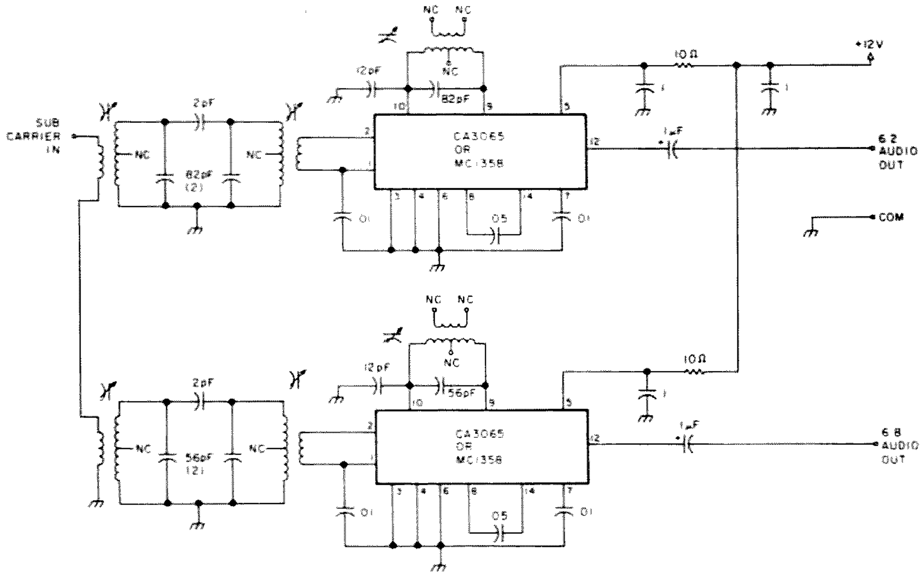

Fig. 6. The subcarrier sound detector uses a single TV sound section IC. Good sound quality results from using cheap FM i-f transformers in a bandpass network on the input.

network. So I used another 10.7-MHz transformer. It works fine."

Can You Really Do It for $100?

A Clint Eastwood movie a few years back, titled *Dirty Harry*, had a good line in it that zeros in on the approach to take with a project such as this. The cool detective character Harry Callahan gave sage advice when he said, "A man must know his limitations." It is perhaps somewhat fitting that you too should consider your own particular abilities with VHF circuitry and parts scrounging. If you've never done any VHF work or think that parts procurement is simply picking up a telephone, then you should reconsider that you can indeed duplicate this receiver for less than 100 bucks.

Now I'm not trying to say this is a tough project—only that you will need to be careful if it is one of your first. The clever tricks of Dwight Rexroad put the price within reach as long as you do the work. It's worth the effort because your learning curve will be up several notches on completion. Besides, this may be one of the best little family attention getters you could try because of the use it will get when you finish it. Just think of all that hamming you can do with everyone else pacified.

Questions? Only those accompanied by an SASE can be answered. Sorry, no calls. Have fun with this one! ■

S.D.-500 WEATHER STATION

CONSOLE
Two large 5" square indicators with red and white graduations on a white background mounted on a black acrylic panel further enhanced by the solidly built mahogany cabinet. Dimensions 16" long x 7½" x4¾" wide

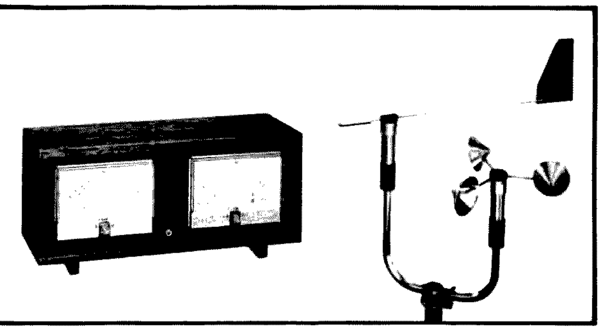
WARRANTY
Against defects in material or workmanship for one year from time of delivery

INSTALLATION
Both transmitters are mounted on an aluminum "U" support supplied with clamp for installation on any 1¼" diameter support (by purchaser)

POWER
115 volt A.C. 60 cycle, includes 9-foot long power cord system fused (⅛ amp.) Power indicator lamp is also provided on console indicator panel

CABLE
.190" diameter 5 conductor, standard length 50 feet Extra cable available in 500 foot increments. Maximum length 300 feet

APPLICATION
This system for use in home, radio stations, small airports, marine installations, schools, industry, air pollution studies Mfg. by TMAC PRODUCTS, P.O. Box 28341, Columbus, Ohio 43228



WIND SPEED TRANSMITTER
This sensitive unit incorporates a three-cup aluminum anemometer coupled to a high grade precision D.C. generator housed in a stainless steel enclosure, range 0-100 M.P.H.

WIND DIRECTION TRANSMITTER
Wind direction is obtained from a counterbalanced aluminum wind vane assembly coupled to a precision linear potentiometer, 360° continuous rotation powered by a regulated 5.0 volt D.C. power supply.

COST COMPLETE
Including 50-foot conductor and mounting hardware is $360.00 plus $4.00 shipping U.S.A. Use VISA, M.C., or C.O.D. All foreign orders add 25% for shipping. No foreign C.O.D.'s

HAM HELP

I need schematics and manuals for the Precision ES-500A oscillograph. I would also like to hear from anyone who can help me increase the dynamic range of my DX-302 receiver. I will pay all copying and postage costs.

Rob Leonard
Lens Ave.
Dayville CT 06241

Free to any high school ham club: back issues of *73*, *QST*, *CQ*, and *HR*. *73*: 1974-present; *QST*: 1973-present; *CQ*: 1975; *HR*: 1974. I will donate these magazines (approx. 150) to any high school ham club that will pay shipping. Send SASE for more details.

Mike Weber WB8RDN
1525 Burney Lane
Cincinnati OH 45230

Wanted: any info available on the Cromemco Z-2 microcomputer system or the following Cromemco boards: ZPU, 16KZ, TU-ART. I am also looking for any information on the Processor Technology Corp. VDM-1 video display board.

Donald Patterson WA1FXK
Box 582
Port Austin AFS MI 48467

I am looking for:

- Information on constructing an interface to monitor slow-scan television using a black and white television set and the audio output of a Hammarlund HQ170-A receiver;
- A Heathkit SB-10 sideband converter in working condition (or easily repairable) with the manuals; and
- More information on the sideband monitor scope construction project written up in the January, 1977, issue of *73 Magazine*, especially concerning the coils in the rf section of this project.

Fred Erickson KA1GCN
105 G St.
Turners Falls MA 01376

I need a glass dial to replace the broken one on my Model 12U159 Zenith console radio. I will pay any reasonable price.

Walter Burdine W8ZCV
Waynesville OH 45068

I am looking for someone who can draw a circuit diagram for me which will show me how to add a product detector to the HRO60 circuit.

Emil Rettig W6BNR
1260 143rd Ave.
San Leandro CA 94578

I need schematic diagrams and, if possible, a service manual for a Data Instruments oscilloscope which includes a 1700/N display unit, a 1Y2 vertical amplifier plug-in, and a 1X2 timebase plug-in. I will pay reasonable photocopying charges and postage or will photocopy and return.

Tim Wulling WB0JZX

Digital Basics

—part I

Joseph J. Carr K4IPV
5440 South 8th Road
Arlington VA 22204

Digital electronics has hit amateur radio—and hobby electronics in general—in a big way! This field of electronic endeavor was once the province of a few freaky computerniks, military electronics technicians, and industrial electronics types, but today, *none* of us can safely ignore digital electronics.

Digital electronics is, in a way, actually simpler than conventional analog electronics because the digital logic devices recognize only two states, i.e., ON and OFF. This fact makes digital circuits similar to relays and mechanical switches. Simple, huh? In fact, some digital circuits are little more than high-frequency electronic versions of simple switches. It is my opinion that anyone who can understand simple relay and switch circuits also can understand the basics of digital electronics! Certainly anyone who can understand the vagaries of single-sideband and FM communications equipment will be able to understand digital electronics.

In this three-part series, we will explore the various forms of IC logic elements: gates, flip-flops, and multivibrators. In this first installment, I am going to give some basic definitions, introduce you to the popular IC-device families, and explore the principal forms of logic gates.

Logic States

I have mentioned that digital circuits respond only to two different input states—ON and OFF—which can be called 1 and 0 (after the two permissible digits of the *binary*, i.e., base 2, number system), HIGH and LOW, or (in older textbooks) "true" and "false." These designations are used to refer to two different voltage levels. In this article, I will stick to the HIGH/LOW designation because it will graphically describe what is actually going on in the circuit.

Transistor-transistor logic (TTL) responds to 0 and +5 volts for the two logic levels. If any other voltage levels are used, then the TTL device will either (1) fail to work, (2) work unpredictably, or (3) burn out (ZZZAPPP!).

Fig. 1 shows the TTL logic levels.

Positive and Negative Logic

You may sometimes hear the terms positive logic and negative logic. These terms sometimes tend to confuse the newcomer; they mean nothing more than how the HIGH and LOW *logic states* are related to *voltage levels*. In *positive logic*, the HIGH is logical 1 and will be a positive voltage (e.g., +5 volts in the case of TTL). The LOW, logical 0, is the 0-volts condition (e.g., in TTL). Logical 0 may be a negative voltage in some CMOS circuits. In *negative logic* these designations are reversed (i.e., HIGH = logical 0 and LOW = logical 1). In the vast majority of uses, positive logic is specified. In fact, the descriptive names given to digital IC devices reflect a bias toward positive logic. This potential confusion is why I prefer HIGH/LOW designations. The 1/0 designation

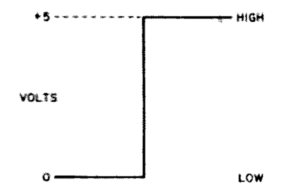

Fig. 1. TTL logic levels: 0 volts is LOW, 5 volts is HIGH.

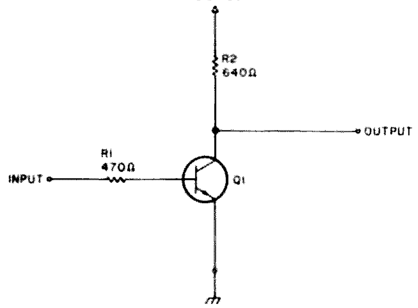

Fig. 2. This typical RTL (resistor-transistor logic) inverter circuit produces a LOW output when the input is HIGH. A LOW input is accompanied by a HIGH output. For RTL, 0 volts is LOW and 3.6 volts is HIGH.

will be reserved for the illustrations and truth tables but keep in mind that *positive logic* is used unless otherwise noted.

Logic Families

A *logic family* is a series of IC devices that may easily be interconnected and which use similar technology in their construction. All of the devices within a given family will have the same input and output circuits, so that direct interconnection is possible.

The only major consideration is whether an output can supply sufficient current to drive all of the inputs that are connected to it. But in any given logic family, output voltage and current levels and input voltage and current requirements are fixed by agreement. They are defined in terms of units of *fan-in* and *fan-out*. This unit is the current requirement of a single standard input at the fixed voltage level. Such an input has a fan-in of *one unit*. If an IC is said to have a fan-out of, say, five, it will *drive five standard inputs*. The device, therefore, can supply sufficient current to drive all five inputs satisfactorily. The total fan-in of all devices connected to any output must be equal to, or less than, the rated fan-out of the output.

The logic families which we will consider are: RTL, DTL, TTL, HTL, ECL, and CMOS. Of these families, CMOS and TTL are the most popular today; RTL and DTL are obsolete and no longer used in new designs. Plenty of older equipment still in use, however, contains RTL and DTL devices.

Speed vs. Power

The principal factors governing the speed (i.e., maximum operating frequency) of a digital IC are the internal resistances and capacitances. If resistances are increased so that power consumption drops, then the RC time constant of the device is longer. Long RC time constants mean slower operating speeds. As a general rule, higher-speed logic families require greater power consumption. CMOS devices, which require very little current (hence are low power), operate well only to 4 or 5 megahertz (MHz), with some devices tooting along to 10 MHz. TTL devices, on the other hand, usually work to 18 or 20 MHz, with some devices operating to well over 80 MHz.

RTL Devices

Resistor-transistor logic (RTL) is an obsolete logic family that was popular in the early to mid-60s. Fig. 2 shows a typical RTL inverter circuit, i.e., a circuit that produces a LOW output when the input is HIGH and a HIGH output when the input is LOW.

RTL logic IC devices used 0 volts for logical 0 and +3.6 volts for logical 1. If the input of the RTL inverter is grounded (i.e., placed LOW), then the output voltage will be HIGH, which in this case means +3.6 volts. But, if the input voltage is +3.6 volts, then the output will be 0 volts.

RTL devices usually carry type numbers in the uL900 range (mostly 8- and 10-pin metal cans) and MC700 series (mostly 14-pin DIPs).

DTL Devices

The next popular IC logic family was the diode-transistor logic (DTL) family. These devices operated at speeds greater than most RTL devices. Fig. 3 shows a typical DTL inverter.

When the DTL input is HIGH, diode D1 is reverse-biased. In that condition, R1 will forward-bias transistor Q1, which in turn forward-biases D2 and Q2. Voltage levels in most digital circuits are selected to *saturate* the transistors, so when Q2 is turned on, it is turned on to full saturation.

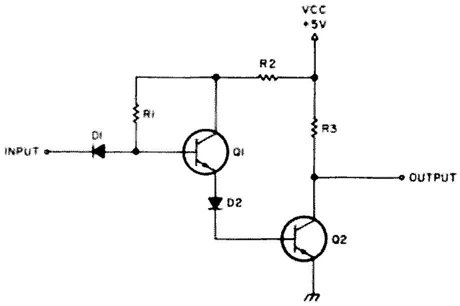

Fig. 3. DTL (diode-transistor logic) offers better speed than RTL. A typical DTL inverter is shown here.

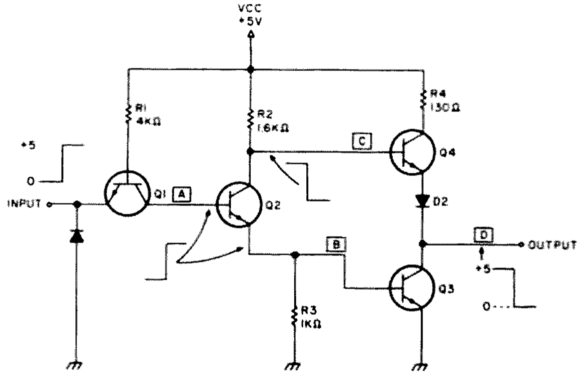

Fig. 4(a). The TTL (transistor-transistor logic) family has LOW values ranging from 0 to 0.8 volts. HIGH is 2.4 to 5.0 volts. An inverter is shown here.

This condition means that the output of the inverter, which is the collector terminal of Q2, goes nearly to ground. The actual voltage $V_{ce(sat)}$ of the transistor is on the order of a few tenths of a volt at most.

When the input is LOW, the cathode of D1 is grounded. Since D1 is now forward-biased, the base of Q1 is essentially grounded. Under this condition, Q1, D1, and Q2 are reverse-biased. With Q2 cut off, then, the output voltage rises to that of Vcc (+). Most DTL devices carry part numbers in the MC800 and MC900 ranges (Motorola designation).

TTL Devices

Probably the most widely used digital IC logic family is the transistor-transistor logic (TTL) family. When most people speak of digital ICs, it is the TTL family of devices to which they refer. Most TTL devices carry type numbers in the 7400 range. (Those devices in the 5400 range are military equivalents to the 7400-series, i.e., a 5447 is a 7447 in uniform. The principal difference between the 5400 and 7400 devices is in the operating temperature range—0 to 80° C for com-

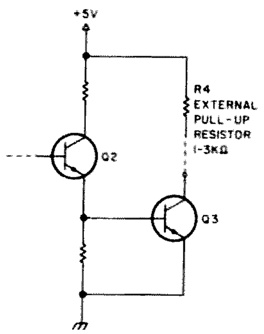

Fig. 4(b). An open-collector TTL circuit results when the output circuit is simplified. An external resistor is needed between the output and +5 volts.

mercial devices and −55 to +125° C for military devices.)

Fig. 4(a) shows the circuit for a typical TTL inverter IC. Like the DTL device, the TTL input acts as a *current source* while the output acts as a *current sink*. The typical TTL input will source 1.8 mA and will be LOW if the voltage is 0 to 0.8 volts and HIGH if 2.4 to 5.0 volts are applied. Performance at values of input potentials between 0.8 and 2.4 volts is not defined, so operation of the devices is unpredictable.

When the TTL input is HIGH, Q1 is cut off, so point A goes HIGH. This condition turns on Q2, forcing point B HIGH and C LOW. We find, then, Q3 is turned on and Q4 is off. This forces the output LOW. Again, the transistors are operated either totally cut-off or totally saturated-on.

If the input is LOW, then exactly the opposite situation occurs: Q1 is turned on (forcing point A LOW), Q3 is off, and Q4 is turned on, i.e., it is connected to Vcc(+).

TTL devices must have a regulated dc power supply of +4.75 to +5.25 volts. In fact, there are some circuits of combinations of devices that require a more limited range of voltages nearer to +5 volts dc. Voltages greater than +5.25 volts often result in a high failure rate of TTL devices.

Some TTL devices are described as being *open-collector* devices. These are essentially the same as regular TTL devices except that the output circuit is modified, i.e., Q4 and D2 are missing. An example of an open-collector circuit is shown in Fig. 4(b). These devices require an external 1k- to 2k-Ohm resistor between the output terminal and the 5-volt dc power-supply line.

Open-collector devices can be useful if you need to tie the outputs of two or more gates together or if you are driving something other than TTL.

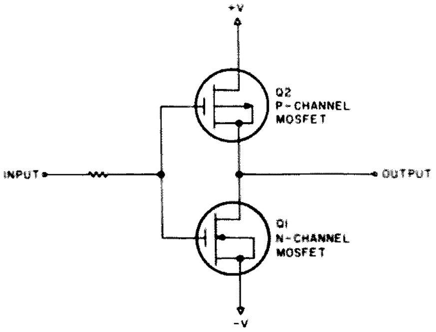

Fig. 5(a). A typical CMOS inverter circuit.

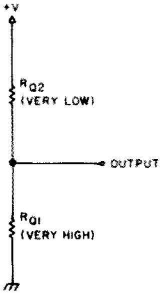

Fig. 5(b). An equivalent circuit for LOW input, HIGH output.

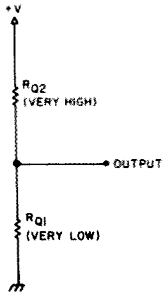

Fig. 5(c). An equivalent circuit for HIGH input, LOW output.

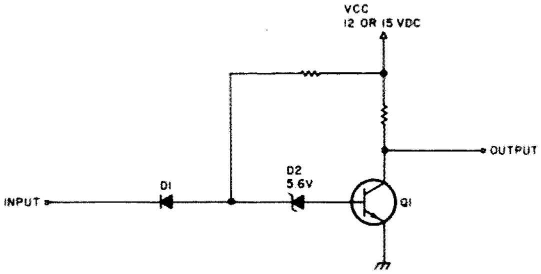

Fig. 6. HTL (high-threshold logic) is useful in applications where noise pulses may be a problem.

CMOS Devices

CMOS IC devices use MOSFET transistors instead of the PNP or NPN bipolar transistors that are used in other logic families. CMOS inputs, therefore, offer a very high impedance. Fig. 5(a) shows a typical CMOS inverter circuit. Note that this family is called *complementary* because the output circuit consists of a complementary pair of MOSFET transistors, i.e., an n-channel and a p-channel in series.

CMOS circuits work over a wide range of voltages, with most devices using a LOW of 0 to 1 volt and a HIGH between 3 and 15 volts. The optimum power supply and HIGH value is usually between 9 and 12 volts. In some instances, a bipolar supply may be used.

CMOS outputs are not directly TTL-compatible, although some specific ICs in the CMOS line are designed to have a TTL-output stage (e.g., the 4049 and 4050 devices). These TTL-compatible devices are often used to directly interface CMOS and TTL devices.

Figs. 5(b) and 5(c) show the equivalent circuits for a CMOS inverter in both possible input conditions, i.e., input HIGH and input LOW. Recall that a p-channel MOSFET turns on when the gate is LOW, while the n-channel device turns on when the gate is HIGH.

Fig. 5(b) shows the situation in which the input is LOW. Transistor Q1 will have a very low (e.g., 200 Ohms) channel resistance. In this case, the output is equivalent to a 200-Ohm resistor to the V+ power-supply line.

In Fig. 5(c), we see the situation in which the input is HIGH. Transistor Q2 now has a very high channel resistance, and Q1 has a very low channel resistance (again, about 200 Ohms). In this case, the output looks like a 200-Ohm resistance to ground, so the output is LOW.

The CMOS ouput stage always looks like a high and low resistor in series across the power supply—see Figs. 5(b) and 5(c). The overall current drain, therefore, is very small.

But CMOS devices do have a problem: They contain MOSFETs, so they are sensitive to static electricity. All A-series CMOS devices (e.g., the 4001A) have this problem, but it is less severe in B-series (e.g., the 4001B) devices. The B-series have built-in diode gate-protection to bypass high static potentials around the sensitive gate structure. Even so, they should be handled with care.

HTL Devices

Noise pulses often are seen by logic circuits as valid input pulses. This problem is especially bothersome in high-speed TTL devices that are normally able to pass high-frequency, short-duration pulses. The solution in noisy environ-

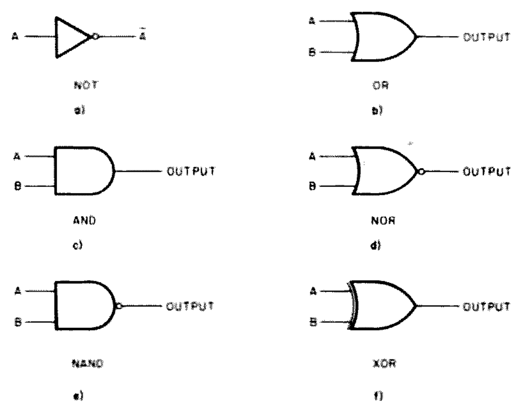

Fig. 7. You can determine the function of a TTL gate by looking at its schematic symbol.

ments is to use a digital IC logic family that requires a high input voltage to trigger. CMOS devices operated at high V− and V+ values meet this requirement, but the older bipolar *high-threshold logic* (HTL) may also be used (Fig. 6).

HTL (also sometimes called *high-noise-immunity logic*, or HNIL) uses V+ values of 12 or 15 volts depending upon the series. As a result, the logic levels also are high, so it requires a bigger noise pulse to cause trouble.

Emitter-Coupled Logic

Up until now we have been talking about *saturated* logic families, i.e., the transistors in the ICs are either all the way on or all the way off (cut off or saturated). *Emitter-coupled logic* (ECL) is called an ac logic family because the transistors are operated in a nonsaturated mode. As a consequence, ECL devices are capable of very fast operation. Most commonplace ECL devices operate to 80 or 120 MHz, while some costly special devices operate to over 1 GHz (that's 1000 MHz!). The usual *prescaler* for a digital frequency counter is nothing more than an ECL frequency divider that divides the 500-MHz input signal down to 50 MHz.

Note that it is necessary to use VHF/UHF circuit design and layout techniques when working with ECL devices. The very high frequencies used are, after all, in the UHF range.

Gates

A digital electronic *gate* is a circuit whose output is HIGH or LOW depending on the input. Gates operate under a set of well-defined rules. The basic forms of digital electronic gates are: NOT, OR, AND, NOR, NAND, and XOR (Exclusive-OR). In the paragraphs to follow, we will discuss all of these basic gates.

NOT Gates

NOT gates, also called *inverters*, produce an output that is the opposite of the input signal. Recall that digital circuits respond only to HIGH and LOW voltage levels. In an inverter circuit, therefore, the output will be HIGH when the input is LOW and LOW when the input is HIGH.

The circuit symbol for the inverter is shown in Fig. 7(a), while the truth table is given in Fig. 8(a). Note that any digital symbol with a *circle* on the output produces an *inverted* output. Similarly, if one or more inputs has a circle on it, then that input is inverted. The rules for the operation of the inverter are:

1) A HIGH on the input produces a LOW output.

2) A LOW on the input produces a HIGH output.

OR Gates

An OR gate will be HIGH if any of its input is HIGH. The symbol for an OR gate is shown in Fig. 7(b), while the truth table is given in Fig. 8(b). The truth table shows the rules of operation for the two-input OR gate, and these are summarized below:

1) If both inputs A and B are LOW, then the output is LOW.

2) If either input A or B is HIGH, then the output is HIGH.

3) If both inputs A and B are HIGH, then the output is HIGH.

AND Gates

The AND gate is the opposite of the OR gate. The AND gate produces a HIGH output only when *all* inputs also are HIGH. The circuit symbol for the AND gate is given in Fig. 7(c), and the truth table is shown in Fig. 8(c). The rules for the operation of the two-input AND gate are:

1) If both inputs A and B are LOW, then the output is LOW.

2) If either input A or B is LOW, then the output is LOW.

3) If both inputs A and B are HIGH, then the output is HIGH.

NOR Gates

The NOR gate is a combination of a NOT gate (inverter) and an OR gate, hence the designation NOR, which means NOT/OR. It is, therefore, an OR gate with an inverted output. The NOR gate is, in fact, sometimes represented in textbooks as an OR gate with an inverter following. The NOR gate symbol, shown in Fig. 7(d), is an OR gate symbol with the circle denoting inversion at the output. The truth table for the two-input NOR gate is shown in Fig. 8(d), and the rules for its operation are summarized below:

(a) NOT

Input	Output
1	0
0	1

(b) OR

Input A	Input B	Output
0	0	0
0	1	1
1	0	1
1	1	1

(c) AND

Input A	Input B	Output
0	0	0
0	1	0
1	0	0
1	1	1

(d) NOR

Input A	Input B	Output
0	0	1
0	1	0
1	0	0
1	1	0

(e) NAND

Input A	Input B	Output
0	0	1
0	1	1
1	0	1
1	1	0

(f) XOR

Input A	Input B	Output
0	0	0
0	1	1
1	0	1
1	1	0

Fig. 8. Understanding a truth table is the key to using logic devices. The 1 designates a HIGH state and the 0 designates a LOW one.

1) If both A and B inputs are LOW, then the output is HIGH.

2) If either input A or B is HIGH, then the output is LOW.

3) If both inputs A and B are HIGH, then the output is LOW.

NAND Gates

The NAND gate is a NOT/AND gate, i.e., an AND gate followed by an inverter. The symbol for the NAND

gate is shown in Fig. 7(e). This symbol is the AND gate symbol with the circle at the output to denote inversion. The truth table for the two-input NAND gate is shown in Fig. 8(e), and the rules are presented in summary below:

1) If both A and B inputs are LOW, then the output is HIGH.

2) If either input A or B is LOW, then the output is HIGH.

3) If both A and B are HIGH, then the output is LOW.

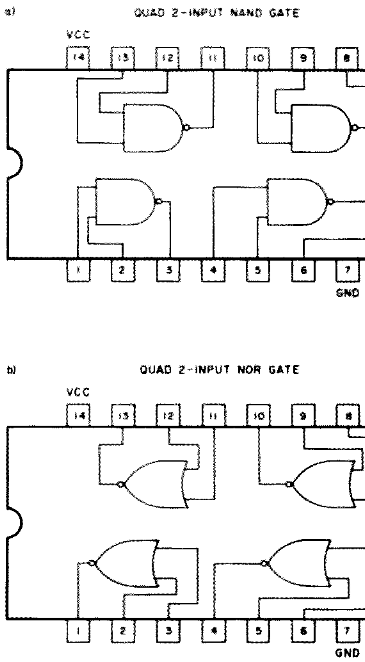

Fig. 9. A chip may contain as many as six individual gates.

XOR Gates

An Exclusive-OR (XOR) gate is like the OR gate discussed earlier except that it will have a LOW output if more than one of its inputs is HIGH. For a HIGH output, there must be one exclusive HIGH input. The XOR gate symbol, shown in Fig. 7(f), is a modified OR gate symbol. The XOR operation is summarized by the truth table in Fig. 8(f) and the rules below:

1) If A and B are both LOW, then the output is LOW.

2) If A is HIGH and B is LOW, then the output is HIGH.

3) If B is HIGH and A is LOW, then the output is HIGH.

4) If A and B are both HIGH, then the output is LOW.

TTL and CMOS Examples

Earlier in this article, I introduced you to several different families of IC digital-logic devices. Of these, several are considered obsolete, so they will not be discussed further. The TTL and CMOS families, however, are very much alive and form the basis of most digital projects today.

TTL/CMOS NAND Gates

In the TTL IC logic family, the most popular NAND gate (and probably the most popular IC) is the 7400 (see Fig. 9). This device contains four two-input NAND gates and usually sells for less than 25¢—or around six cents per gate. Each of the four NAND gates in the 7400 package is an independent entity, but shares the common power supply and ground connections (pins 14 and 7, respectively).

The 7401 and 7403 are similar to the 7400 except that they are open-collector devices. This means that pull-up resistors are needed, i.e., one 2k- to 4k-Ohm resistor from each output to the +5 volt line.

The 7430 is an eight-input NAND gate (one per 14-pin DIP package). The 7430 device, therefore, has eight distinct inputs... and all eight must be HIGH before the output drops LOW. If any one of the eight inputs remains LOW, then the output stays HIGH. Since most microcomputers today are eight-bit machines, the 7430 is often used as an address, or I/O port, decoder.

The 7410 and 7420 are three- and four-input TTL NAND gates, respectively.

In the CMOS line, we also have several different types of NAND gates. The 4011 is a quad two-input NAND gate that is reminiscent of the 7400. The 4012 device is a dual four-input NAND gate. All four inputs of either gate must be HIGH for the respective output to be LOW. The 4023 device is a triple three-input NAND gate, while the 4068 is an eight-input NAND gate.

TTL/CMOS NOR Gates

The 7402 TTL NOR gate is by far the most common example from the TTL line and is almost as popular as the 7400 device. The pinouts for the 7402 are shown in Fig. 9(b)—see 9(a) for pinouts for the 7400, for comparison. Note that the pinouts of the 7400 and 7402 are different, as are their logical responses.

And Now...

We have just gotten our toes wet in the study of digital electronics. In part II, we will progress a little further: We will be up to our ankles in flip-flops. For now, however, you have sufficient information to begin experimenting with flip-flops. ■

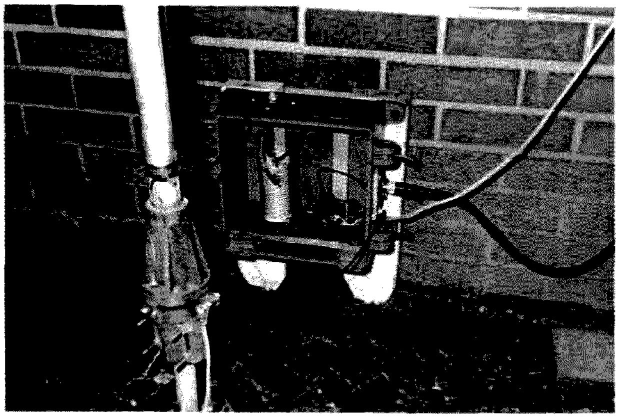
There has been much written about antennas, a good portion of which has been about verticals. This is no great scoop and probably has been told in one form or another many times over. It is, however, an easy way to achieve efficiency out of a single antenna for both forty and seventy-five meters.

Of course, the most commonly used method to work multiband on a single antenna is with traps. I have used trapped antennas for many years—allband trapped; twenty, forty, and eighty trapped; ten, fifteen, and twenty trapped; and even forty/seventy-five trapped. I have always experienced many problems with traps, the greatest of all being the limitations in bandwidth, i.e., swr. The method described here solves all of the problems, including bandwidth and high swr.

I have been running a monoband, forty-meter vertical for some time and an additional antenna for seventy-five. After disapproving looks from my neighbors at the half-wave doublet strung from one end of the house to the top of my beam tower, with the coax dangling halfway in between, I decided to do something.

The sketch and the picture tell the rest of the story. The mast I used was 1¼" aluminum tubing, and the height was 29'6" from base insulator to top-hat. The top-hat was made from old TV antenna elements and consisted of eight "spokes," each 24" long. There are several methods of fastening the spokes to the vertical tubing. I used a 5"-diameter piece of aluminum, flattened the end of the tubing, and bolted it to the circular plate. Be sure to use two bolts to ensure that the spokes stay in place and don't swivel out of line.



A close-up of the relay/tuner box showing the #6 wire connected to the base of the aluminum tubing, likewise the ground wire attached to the bottom half of the base.

The coil I used was an old B&W, 2" in diameter, with 20 turns of #12 wire. The tap strap was RG-59/U coax shielding removed from the cable and flattened. It should be as short as possible, and when the final position is determined, it should be soldered to the coil turn solidly. The relay was an old one from the junk box, but anything will do *if* it makes good, solid contact when closed. It could be 110 V ac or some optional dc voltage you might happen to have handy in the shack. Be sure to use correct voltage as indicated by the spec on the coil, since the relay will be closed during all forty-meter usage and we wouldn't want it to get too warm from too much current flowing through it.

Of course, the relay and coil should be enclosed. A metal enclosure did not seem to affect the tuning of the coil in the slightest. I just happened to have an old cast-aluminum box once used in the military for an antenna tuner. It already had a PL-259 connector on one side and a feedthrough insulator on the top. Anything you can come up with will do the trick.

Tuning the antenna is very simple. Since I already had the antenna working on forty meters, no adjustment to length was required. However, if you start from scratch, I suggest you make the mast adjustable by using the top half inserted into the bottom half and a hose clamp to fasten permanently when the correct length is determined. If you are proceeding from scratch, you will want to start with the antenna a little longer than the ultimate will be. Use a grid-dip meter or an in-line swr meter and shorten the mast two or three inches at a time until it resonates in the portion of the forty-meter band you desire. The change-over relay must be closed when tuning the antenna for forty meters—at this point the shorting strap on the coil need not be fastened at all.

Now that we have the antenna working on forty, we will resonate it on seventy-five. I used a CRC 100-uF, 5000-volt capacitor across the coil. This is a tubular capacitor and I suspended it inside the coil, soldering it to each end of the coil. Of course, if you use some other value or the coil size is not the same, you will have to make necessary changes in the tuning procedure.

The procedure I used was to open the relay, leaving the entire coil in series with the forty-meter antenna. See what the resonant point is with all of the coil in. If you can't resonate it at your desired frequency, you will have to either add to the coil turns or to the capacitance. In my case, it resonated below the 3.8 MHz—meaning the coil was too long. I tried the shorting strap two turns down from the top and checked again, but it still was too long. I moved it two turns at a time until I found the correct turn for 3.8 MHz. It turned out to be the fifth turn from the top. I soldered it firmly to that turn, closed the enclosure, and that was it.

I found that at forty meters my antenna had an swr of 1.3 to 1 from 7.1 to 7.3 (making it flat across the phone band) and 1.4 to 1 at 7.0 MHz—just about as good as anyone could expect. On seventy-five the swr was 1.7 to 1 at 3.7 MHz, 1.2 to 1 at 3.8, 1.7 at 3.9, and 1.75 at 4.0 MHz. It sure beats all those unsightly overhead wires.

The control box for the change-over switch is a small 2" × 3½" aluminum item, common in any parts store or out of your junk box at home. The switch is a simple single-throw/single-contact which I found in my junk box. I wired a pilot light across the "on" side so that I could easily tell when the switch was in the forty-meter position. Another color pilot light could be wired across the other side of the switch to indicate it was in the seventy-five-meter position—but I didn't think that was necessary. In addition, I wired the switch to my master switch which turns on the rig, so it would be impossible to leave the relay on when the shack is not occupied. It probably wouldn't hurt it to leave it on all night since it draws little current, but everything in my shack is turned on by a master switch and I made no exception for the relay circuit. ■

New Automatic Antenna Tuner Auto-Track Model AT 2500

Check these specifications...

- Auto-Track antenna tuners can handle power in excess of 2500 Watts PEP
- Frequency Range: Continuous from 3—30 MHz
- Average automatic tune-up time is 15 seconds
- Impedance matching: 10 ohms to 300 ohms to 50 ohms resistive
- Direct reading SWR & Power meters.

Write for complete specifications.

The New Standard in High Performance Repeater Control...

☐ FRIENDLY, POWERFUL, EASY TO USE - Human engineered to be your "assistant" at the repeater, with capability second to none.

☐ REMOTELY CONFIGURABLE - Change command codes, messages, tone characteristics, timing, and more, remotely! Reliable storage in E²PROM.

☐ Room to grow: BUILT IN! - Features intelligent remote control and meter readback. Interfaces to synthesized remote bases and links. Planned software upgrade path.

☐ SUPPORT - We invented the "Computer Controlled Talking Repeater," so we know how to provide the applications assistance, and long term support so crucial to a computer based product.

☐ BRING YOUR REPEATER SYSTEM INTO THE 80'S - Starting at less than $1200!

The RC-850 Repeater Controller!

Call or write for detailed specifications.

Manual and demonstration cassette tapes available separately.

The J-Pole Love Affair

—not for CB

Would you like to try a nifty antenna for 2 meters that is inexpensive (less than $5.00 usually), is lightweight and easily portable, exhibits gain over the typical 5/8-wavelength-type antenna, requires no ground plane at all, and *nobody* mistakes for a CB antenna?

Several years ago while attending business college at New Mexico State University in Las Cruces, I was bitten by the 2-meter FM bug. There was lots of 2-meter activity in town, and I, being limited in funds, began playing with various types of home-brew antennas. I stumbled on the J-pole section of the ARRL antenna book and began experimenting with various J designs.

I had seen a couple of old-timers using the J antenna made from CB whips and they complained of the J's susceptibility to breakage when whacking trees or other overhead obstructions; they also complained of the difficulty in building a proper balun with which to couple the feedline to the antenna.

In my case, even CB whips were out of my price range, so I cast about for alternatives. I had often noticed the colorful fiberglass "bicycle flags" on the kids' bikes and how much they resembled antennas. I decided to try them. These rods are really very nice for all types of hamming needs. They are sometimes fiberglass and sometimes plastic, and of course the fiberglass ones are the best buy. They seem to cost around $.99 to $5.00 depending on whether they're on sale or not.

I was in love with the J design from the first. The first few I built were tricky to tune and quite fragile, but they worked well. I went through several designs before settling on the present one. I discovered that doing away with the balun arrangements simplified the matching procedure, improved the antenna's performance, and greatly increased the longevity of the antenna (less to break or vibrate loose). As you may discern by looking closely at this antenna, there are several ways to construct it. Use your own imagination and ingenuity to make use of what you have to build it. You might wish to coat the whole antenna assembly with boat varnish or other sealant *after* the coax is attached and tuned satisfactorily.

See Figs. 1 and 2 for assembly details. You may note in Fig. 3 that I use the bike mounting bracket that comes with the pole. If it is mounted as shown, the mount will have a hinge action that will allow the antenna to harmlessly fold back when a low overhead obstruction is encountered, but keep the device erect while driving normally. Also, one of the great advantages of this antenna is

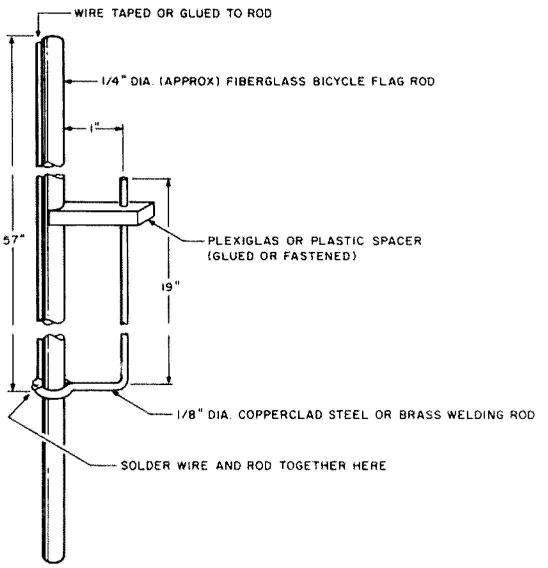

Fig. 1.

that, requiring no ground plane, it may be placed essentially anywhere on the vehicle you wish without adversely affecting its performance. Offered in Fig. 3 are 3 variations in mounting that should adapt to most vehicles. The bolt-action mount saves the antenna (and your car) when you hit tree limbs, etc.

This antenna has several natural applications: motorcycles and bicycles, 18-wheelers and recreational vehicles, backpack frames, as a hand-held for great gobs of gain with portables, bumper or headache-rack mounting on any vehicle, easy mounting on light bars for public safety vehicles, and installation against the window in a motel or apartment!

To adjust the antenna for lowest swr, merely slide the shield and center conductor up and down on the lower portion of the J until the lowest swr point is found. The wire and welding rod need to be scraped and clean for this procedure. Solder the connections when you find the right point. If you have any difficulty, try reversing the shield and center conductor connections. The antenna will work either way as long as you can get it to match properly.

I have compared this antenna to many of my own friends' 5/8-wave 3-dB gain antennas. I haven't seen one yet that this J-pole will not compare to or outperform. Usually the J-pole, mounted or held near the competing antenna's former location, exhibits about an S-unit gain on receiving a weak repeater. Try it sometime. (By the way, one S-unit compares roughly with 1 dB on all the imported radios I've checked.) I keep a spare antenna around the house for motel mobile and it's easy to walk out to a friend's car, get a meter reading on a distant repeater, then remove his antenna and hold the J-pole temporarily near the same spot. Usually the J-pole will have noticeable gain. I theorize the greater height of the J-pole plus the lack of ground sensitivity account for the difference.

I have shown this antenna to several engineer-type friends who shake their heads in disgust over its simplicity and lack of balun, etc. However, they all agree that for some reason it works well . . . and that's what it's all about, isn't it?

It would not be fair to ignore some disadvantages with this antenna. It is *not* as sturdy as most commercially-made antennas. Weather, vibration, wind, and corrosion will necessitate repairing the antenna occasionally—depending on your climate. (Usually the soldered connections give the most frequent trouble. I usually have to repair mine every 9 months or so.) This antenna may exhibit some minor directivity. However, *all* antennas on vehicles are directive to some degree, depending on the mounting location. Depending on the rigidity of your rod, you may find under road speeds the swr changing as the antenna bends backward. I have good luck in mounting the antenna with the stub facing forward or sideways so the spacing of the stub doesn't change as the antenna flexes.

In conclusion, I have presented here a simple, inexpensive, and very effective 2-meter antenna. It can be adapted easily to 220 or 450 use by experimentation and scaling of the dimensions. None of my antennas has ever been stolen and no one has ever asked me if I monitored channel 19. It may be, as some engineers insist, much like a bumblebee (too heavy to fly). However, if you try it, you will agree it works anyway! ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

HARRISBURG PA
SEP 5

The Central Pennsylvania Repeater Association will hold the 9th annual Hamfest/Computerfest on September 5, 1982, beginning at 6:00 am, at the Harrisburg Farm Show parking lot, off the Route 81 Cameron Street exit. (Follow the signs to the Farm Show building.) Registration is $3.00; sellers' 10-foot space, $5.00; tailgating, $1.00. Talk-in on 144.87/5.47, 146.16/.76, and .52. For more information or a map, contact Irvin Sanders K3IUY, RD #3, Box FA53, Harrisburg PA 17112, or phone (717)-469-2185.

HAMBURG NY
SEP 10-11

Ham-O-Rama '82 will be held on Friday and Saturday, September 10-11, 1982, at the Erie County Fairgrounds near Buffalo NY. Hours are 6:00 pm to 9:00 pm on Friday and 7:00 am to 5:00 pm on Saturday. Advance tickets are $3.50 (deadline: September 1st) and tickets at the gate will be $4.50. Children under 12 will be admitted free. The outside flea market is $3.00 per space and the inside flea market is $10.00 per space. Features will include new equipment displays, computers, technical programs, ladies' programs, and valuable awards. Talk-in on 146.31/.91. For advance tickets, send an SASE to Dave Baco WA2TVT, 130 Vegola Avenue, Cheektowago NY 14225.

AUGUSTA ME
SEP 10-12

The Augusta Emergency Amateur Radio Unit will hold the ARRL-approved Northeast Area Hamfest on September 10-12, 1982, at Windsor Fairgrounds, located just off Route 17, 10 miles east of Augusta ME. Facilities for campers will be available. Activities will include a flea market and regularly scheduled speakers and demonstrations, as well as the usual events. Talk-in on 146.22/.82 and .3940.

AUGUSTA NJ
SEP 11

The Sussex County Amateur Radio Club will hold its fourth annual SCARC '82 hamfest on Saturday, September 11, 1982, at the Sussex County Farm and Horse Show grounds, Plains Road off Rte. 206, Augusta NJ, just north of Newton. Pre-registration for outdoor flea-market sellers is $4.00; at the gate, $5.00. Pre-registration for indoor flea-market sellers is $5.00; at the gate, $6.00. Other registration is $2.00. There will be door prizes and acres of free parking. Talk-in on 147.90/.30 and 146.52. For additional information or pre-registration, write Sussex County Amateur Radio Club, PO Box 11, Newton NJ 07860, or Lloyd Buchholtz WA2LHX, 10 Black Oak Drive, Vernon NJ 07462.

UNIONTOWN PA
SEP 11

The Uniontown Amateur Radio Club will hold its 33rd annual gabfest on Saturday, September 11, 1982, on the club grounds located on the Old Pittsburgh Road, just off Route 51 and the 119 bypass, Uniontown PA. The pre-registration fee is $2.00 each or 3 for $5.00. There will be free parking, free coffee, and free swap and shop setups with registration. Prizes will be awarded, including a first prize of a Ten-Tec Argosy 525 HF. Featured will be a DX contest, demonstrations, and refreshments. Talk-in on 147.045/.645, 144.57/145.17 and 146.52/.52. For further information, contact UARC Gabfest Committee, c/o John T. Cermak WB3DOD, PO Box 433, Republic PA 15475, or phone (412)-246-2870.

MARION IN
SEP 11

The Grant County Amateur Radio Club Hamfest will be held on Saturday, September 11, 1982, at McCarthy Hall, Marion IN, from 8:00 am until 4:30 pm. Admission is $2.00 in advance and $3.00 at the gate. There will be good home cooking, hourly drawings, and major prizes. Talk-in on 146.19/.79 and 146.52. For more information or tickets, send an SASE to Beecher Waters WB9YHF, RR #1, Box 357, Converse IN 46919.

MELBOURNE FL
SEP 11-12

The Platinum Coast Amateur Radio Society will hold its 17th annual hamfest and indoor swap-and-shop flea market on September 11-12, 1982, at the Melbourne Auditorium, Melbourne FL. Admission is $3.00 in advance and $4.00 at the door. Swap tables are $10.00 for one day and $15.00 for both days. There will be unlimited free parking, a tail-gate area, air-conditioned swap and exhibit area, awards, forums, and meetings. Talk-in on .25/.85 and .52/.52. For reservations, tables, and information, write PCARS, PO Box 1004, Melbourne FL 32901, or call (305)-245-5116.

WARNER ROBINS GA
SEP 11-12

The Central Georgia Amateur Radio Club (CGARC) will hold the fourth annual Central Georgia Hamfest and ARRL Georgia State Convention on Saturday and Sunday, September 11-12, 1982, at the Warner Robins Recreation Center, 800 Watson Boulevard, Warner Robins GA. Donation tickets will be available at the door for $1.00 each, 6 for $5.00, or 13 for $10.00. There is no registration fee. Indoor or outdoor flea market space is $3.00 per day (bring your own table). Features will include meetings, forums, a Sunday morning breakfast for the Georgia State CW Association, activities for YLs and harmonics, a Friday night hospitality room, and Saturday night pickin' and grinnin'. Talk-in on 146.25/.85. For more information, contact Jim Piper W4HON, 618 American Boulevard, Warner Robins GA 31093.

BUTLER PA
SEP 12

The Butler County Amateur Radio Association will hold its annual hamfest on Sunday, September 12, 1982, from 9:00 am to 4:00 pm, at the Butler Farmshow Grounds at Roe Airport, Butler PA. Fly-in at Butler Farmshow Airport. Admission is a $1.00 donation and children under 12 will be admitted free. Overnight campers are welcome and food and refreshments will be available. There will be an indoor flea market (vendor space will be $3.00 per 8-foot table), a free outside flea market, free parking (including for the handicapped), and prizes, including a Kenwood TS-830S HF transceiver. Talk-in on 147.96/.36, .52, and 147.84/.24. For additional information, contact Leighton Fennell, Crestmont Drive, RD 6, Butler PA 16001, or phone (412)-586-9822.

WILLIMANTIC CT
SEP 12

The Natchaug Amateur Radio Association will hold a giant flea market on Sunday, September 12, 1982, from 9:00 am until 4:00 pm, at the Elks home, off Rtes. 32 and 6, Willimantic CT. Tables may be reserved in advance for $5.00 until September 1st; after that date, they will be $7.00 at the door. Admission is $1.00. There will be free parking, as well as raffles and door prizes. Talk-in on 147.30 and 147.90/.50. For further information, contact Clifton Pease KA1HYW, 268 Main Street, Willimantic CT 06226, or phone (203)-456-1432 after 4:00 pm.

CARTERVILLE IL
SEP 12

The Shawnee Amateur Radio Association will hold its 28th hamfest, SARAFEST '82, on Sunday, September 12, 1982, at John A. Logan College, Highway 13, Carterville IL. Admission is $2.00 in advance and $3.00 at the door. There will be an air-conditioned flea market, forums, computers, refreshments, contests, and prizes, including a first prize choice of a Kenwood 130S HF transceiver, a microwave oven, an RCA color TV, or an automatic dishwasher. Talk-in on 146.25/.85, 146.52, and 3.925. For further information, contact William May KB9QY, 800 Hilldale Avenue, Herrin IL 62948, or phone (618)-942-2511 days.

PORT JEFFERSON LI NY
SEP 12

The Suffolk County Radio Club will hold the 5th annual flea market on Sunday, September 12, 1982, at the Odd Fellows Hall, Jayne Boulevard, Port Jefferson Station NY. The rain date will be September 19th. Admission for buyers is $1.50 each and YLs, XYLs, and harmonics will be admitted free. Sellers, including car and driver, will be charged $3.50 each. There will be raffles and food and drink, plus drawings for door prizes. Talk-in on 145.21/144.61. For additional information, contact Floyd WA2SDI at (516)-234-9376 after 6:00 pm.

GRAND RAPIDS MI
SEP 18

The Grand Rapids Amateur Radio Association, Inc., will hold its annual swap and shop on Saturday, September 18, 1982, at the Hudsonville Fairgrounds. There will be prizes and dealers, with an indoor sales area and an outdoor trunk swap area. Gates will open at 8:00 am for both swappers and the public. Talk-in on 146.16/.76. For more information, write Grand Rapids Amateur Radio Association, Inc., PO Box 1248, Grand Rapids MI 49501.

PEORIA IL
SEP 18-19

The Peoria Area Amateur Radio Club will hold the Peoria Superfest '82 on September 18-19, 1982, at the Exposition Gardens, W. Northmoor Road, Peoria IL. The gate opens at 6:00 am; the commercial building at 9:00 am. Admission is $3.00 in advance or $4.00 at the door. Activities include forums, amateur radio and computer displays, a free flea market, and, on Saturday evening, an informal get-together at the Heritage House Smorgasbord. At the hamfest site, there will be free movies Saturday night. Full camping facilities are available, as well as a Sunday bus to Northwoods Mall for the ladies. Talk-in on 146.16/.76. For more information, contact Charles W. Kuhn WD9EGW, PAARC Director, 7005 N. Tobi Lane, Peoria IL 61614.

MT CLEMENS MI
SEP 19

The L'Anse Creuse Amateur Radio Club will hold its 10th annual swap and shop on Sunday, September 19, 1982, from 9:00 am to 3:00 pm, at the L'Anse Creuse High School, Mt. Clemens MI. Take I-94 eastbound to the Metropolitan Parkway exit; then take the Metropolitan Parkway to Crocker; go left on Crocker to Reimold and then right on Reimold to the last school, L'Anse Creuse High School. Admission is $2.00 at the door or $1.00 in advance. FCC representatives will be there, as well as plenty of new and used gear. There will be lots of food and parking, plus hourly prize drawings. Prizes include a first prize of $250, a second prize of $100, and a third prize of $50. Talk-in on 147.69/.09 and 146.52. For more information, send an SASE to Maurice Schietecatte N8CEO, 15835 Touraine Ct., Mt. Clemens MI 48044.

AUGUSTA GA
SEP 19

The Augusta Amateur Radio Club will hold its annual hamfest on September 19, 1982, at the Julian Smith Casino in Augusta GA. Admission is $3.00 per person; tailgating will be $2.00. There will be prizes, a barbecue, bingo, and a hospitality room on September 18th from 4:00 pm to 11:00 pm at the Ramada Inn West, Rooms 108-110. Talk-in on 147.72/.12. For more information, contact John Schumacher N4DOU, PO Box 3072, Augusta GA 30904, or phone (404)-860-4460 from 6:00 pm to 9:00 pm EDT.

PENNSAUKEN NJ
SEP 19

The South Jersey Radio Association will hold its 1982 annual hamfest on Sunday, September 19, 1982, from 8:00 am to 4:00 pm, at Pennsauken High School parking lot, Route 73 and Remington Avenue, Pennsauken NJ. There will be door prizes, food, and fun. Admission is $3.00; tailgate sales are $5.00. Talk-in on 146.220/146.820 and 146.52. For ticket sales and more information, contact Fred Holler W2EKB, 348 Bortons Mill Road, Cherry Hill NJ 08034.

VENICE OH
SEP 19

The Forty-Fifth Annual Cincinnati Hamfest will be held on Sunday, September 19, 1982, at Stricker's Grove, State Route 128, Venice (Ross) OH. Admission and prize ticket, $5.00. There will be exhibits and booths, prizes, a flea market (radio-related products only), a hidden transmitter hunt, and an air show. Food and refreshments will be available. For further information, write Lillian Abbott K8CKI, 317 Greenwell Road, Cincinnati OH 45238.

MONTGOMERY AL
SEP 19

The Central Alabama Amateur Radio Association will hold its 5th annual hamfest on Sunday, September 19, 1982, at the Civic Center, downtown Montgomery AL. There will be free admission, free parking, and 22,000 square feet of air-conditioned

activities, including a flea market. Setup will be at 0600, doors will be open from 0800 to 1500, and a prize drawing will be held at 1400 CDST. Restaurants and motel accommodations are located within a short walk of the Civic Center and refreshments will be available in the Civic Center. Talk-in on 146.04/.64, 146.31/.91, 147.78/.18, or 147.045/ ± 600T. For further information or market reservations, write Hamfest Committee, 2141 Edinburgh Drive, Montgomery AL 36116, or call Phil at (205)-272-7980 evenings.

NEW KENSINGTON PA
SEP 19

The Skyview Radio Society will hold its annual hamfest on Sunday, September 19, 1982, from noon until 4:00 pm, at the club grounds on Turkey Ridge Road, New Kensington PA. Registration fee is $2.00; vendors, $4.00. There will be awards. Talk-in on .04/.64 and .52.

NEWTOWN CT
SEP 19

The Candlewood Amateur Radio Association will hold a flea market and auction on Sunday, September 19, 1982, rain or shine, at the Essex House, Rte. 6, exit 8 off I-84, Newtown CT, from 10:00 am to 4:00 pm. Admission fee of $1.00 includes one door prize chance. Tables are $6.50. Featured will be an equipment raffle of a TR-2500 handie-talkie, dealers, and a magic show for the kids. Refreshments will be available. Talk-in on 147.72/.12. For advance table reservations, write CARA, PO Box 188, Brookfield Center CT 06805. For more information, call George WB2THN at (914)-533-2758, Ken KA1GDS at (203)-744-6953, or George AF1U at (203)-438-0549.

ELMIRA NY
SEP 25

The Elmira Amateur Radio Association will hold the seventh annual Elmira International Hamfest on September 25, 1982, at the Chemung County Fairgrounds. Breakfast will be available for several hours after the gates open at 6:00 am. Advance tickets are $2.00 and tickets at the gate are $3.00. Featured will be tech talks, a free flea market, dealer displays, and prizes, including a grand prize of an Icom IC-730. Friday night camping will be available on a limited basis at the fairgrounds and lunch will be available starting at 11:00 am on Saturday. Talk-in on 147.96/.36, 146.10/.70, and 146.52. For advance tickets, write John Breese, 340 West Avenue, Horseheads NY 14845.

WICHITA FALLS TX
SEP 25-26

The Wichita Amateur Radio Society will hold its first annual hamfest on September 25-26, 1982, at the National Guard Armory, Wichita Falls TX. Pre-registration closes Wednesday, September 22, 1982, and is $4.00 per person and $3.00 per swap table. Registration at the door is $5.00 and starts at 8:00 am on Saturday and Sunday. There is free shuttle service from the Kickapoo Airport (¼ mile south), free RV parking without hookups at the armory, and a concession stand open both days. There will be dealer displays, an inside flea market with 24-hour security, scheduled ladies' activities and prizes, contests, meetings, a grand prize, and other prize drawings. Talk-in on 146.34/.94 and 147.75/.15. For more information and pre-registration, write to WARS Hamfest, PO Box 4363, Wichita Falls TX 76308.

GRAYSLAKE IL
SEP 25-26

The Chicago FM Club will hold the 12th annual Radio Expo on September 25-26, 1982, from 9:30 am to 4:00 pm, at the Lake County Fairgrounds at the intersection of Rtes. 45 and 120, Grayslake IL. Admission is $3.00 in advance and $4.00 at the door. There will be displays, seminars, technical talks, a flea market (open from 6:00 am to 6:00 pm), full food services, a free camping area, acres of free parking, ladies' programs, children's events, and prizes. Talk-in on 146.16/146.76 and 222.52/224.10. For more information and/or reservations, contact Harold G. Rowlett, c/o Radio Expo, PO Box 1532, Evanston IL 60204, or phone (312)-588-3976.

BEREA OH
SEP 26

The Cleveland Hamfest Association will present the 8th annual Cleveland Hamfest on Sunday, September 26, 1982, at the Cuyahoga County Fairgrounds in Berea OH, from 0800 to 1700 hours. Activities will include indoor exhibits, forums, a ladies' program, and an outdoor flea market with separate parking. Food services will include both breakfast and lunch. There will be three main prizes and a mobile check-in prize. Talk-in on 146.52. Advance tickets are $2.50 prior to August 31st and $3.00 at the door. For more information, contact the Cleveland Hamfest Association, PO Box 27211, Cleveland OH 44127.

NEW LONDON NH
SEP 26

The 6th annual Connecticut Valley FM Association Hamfest/Flea Market will be held on Sunday, September 26, 1982, from 9:00 am to 5:00 pm, at King Ridge Ski Area, New London NH. Adult admissions are $2.00, a flea-market setup is $5.00, and children under 16 will be admitted free. King Ridge will have the food concession. For more information, contact Francis Callahan KA1BWE, Box 173, East Wallingford VT 05742.

ADRIAN MI
SEP 26

The Adrian Amateur Radio Club will hold its 10th annual hamfest on Sunday, September 26, 1982, at the Lenawee County Fairgrounds, Adrian MI. Talk-in on 146.31/.91 (W8TQE). For tickets, tables, and more information, contact the Adrian Amateur Radio Club, Inc., PO Box 26, Adrian MI 49221.

GAINESVILLE GA
SEP 26

The 9th annual Lanierland ARC Hamfest will be held on September 26, 1982, beginning at 9:00 am, in the Holiday Hall at Holiday Inn, Gainesville GA. There will be free tables and an inside display area for dealers and distributors (doors will open at 8:00 am for dealer setups). Prize tickets are $1.00 each or 6 for $5.00. Food and drink will be available, as well as a large parking lot for a free flea market. A boat anchor auction will be held and all activities and facilities will be free. Talk-in on 146.07/.67. For information and free space to dealers, contact Phil Loveless KC4UC, 3574 Thompson Bend, Gainesville GA 30506, or phone (404)-532-9160.

BOXBORO MA
OCT 2-3

The Federation of Eastern Massachusetts Amateur Radio Associations will hold the New England ARRL Convention on October 2-3, 1982, at the Sheraton Boxboro Hotel, Route 495 at Route 111, Boxboro MA. On Saturday the hours will be 9:00 am to 5:00 pm and on Sunday, 10:00 am to 5:00 pm. Early-bird registration is $4.00. The Saturday evening banquet, dance, and show is $13.50. Features will include a Wouff Hong midnight ceremony Saturday and YL programs on both days. For reservations and advance registration, send an SASE to Arthur Tomkinson W1THT, 9 Oliver Terrace, Revere MA 02151 and make checks payable to FEMARA.

WARRINGTON PA
OCT 2-3

The Pack Rats sixth annual Mid-Atlantic VHF Conference will be held on Saturday, October 2, at the Warrington Motor Lodge, Rte. 611, Warrington, PA. Advance registration $3.00; at the door, $4.00. Price includes admission to the 11th annual Pack Rats Hamarama on Sunday, October 3, at the Bucks County Drive-In Theater, Rte. 611, Warrington, PA. Admission to the flea market $2.00 and tailgating $4.00 per space. Bring your own table. Gates open at 7:30 am. Talk-in via W3CCX on 146.52. Information for both events is available from Hamarama '82, POB 311, Southampton PA 18966 or Lee A. Cohen K3MXM at (215)-635-4942.

ROCK HILL SC
OCT 3

The York County Amateur Radio Society will hold its 31st annual hamfest on Sunday, October 3, 1982, at Joslin Park, Rock Hill SC, starting at 0700. Pre-registration is $3.00; at the gate, $4.00. There will be prizes. Talk-in on 146.43/147.03 and 146.52. For additional information, contact YCARS, Box 4141 CRS, Rock Hill SC 29730.

YONKERS NY
OCT 3

The Yonkers Amateur Radio Club will hold its electronics fair and flea market on Sunday, October 3, 1982, from 9:00 am to 5:00 pm, rain or shine, at Yonkers Municipal Parking Garage, corner of Nepperhan Avenue and New Main Street. Admission is $2.00 each; children under 12 will be admitted free. Sellers' spaces are $6.00 (bring your own table) and include one admittance. Gates will be open to sellers at 8:00 am. There will be live demonstrations, hourly prizes, an auction, free parking, refreshments, and unlimited free coffee all day. Talk-in on 146.265/146.853, .52, or CB channel 4. For further information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

VIRGINIA BEACH VA
OCT 9-10

The ARRL Virginia State Convention and Tidewater Computer Show-Hamfest-Electronic Flea Market will be held on Saturday and Sunday, October 9-10, 1982, from 9:00 am to 5:00 pm both days, at the pavilion in Virginia Beach VA. Admission is $3.50 for both days. Flea-market tables are $5.00 for one day or $8.00 for both days; commercial flea-market tables are $15.00 for both days, and commercial booths are $30.00 for both days. Featured will be dealers, special displays, forums, computers, satellite equipment, special XYL programs, and a cocktail party Saturday night. There will be an advance ticket drawing for a hand-held transceiver, as well as many valuable door prizes. For more information and/or tickets, contact Jim Harrison N4NV, 1234 Little Bay Avenue, Norfolk VA 23503, or phone (804)-587-1695.

ASHEVILLE NC
OCT 9

The Western North Carolina Amateur Radio Society will hold its seventh annual Autumnfest on October 9, 1982, at the Asheville Civic Center, Asheville NC. Admission is $3.00 in advance and $4.00 at the door. Flea market tables will be $5.00 at the door. Activities (all indoors) will include the McElray Memorial CW Competition, bingo for the ladies, and dealer and flea market tables. Travel, motor home, and camping facilities will be available. Talk-in on .31/.91, .16/.76, and .52. For more information, contact WCARS, PO Box 1488, Asheville NC 28802.

PARAMUS NJ
OCT 10

The Bergen ARA will hold a ham swap 'n sell on October 10, 1982, from 8:00 am to 4:00 pm, at Bergen Community College, 400 Paramus Road, Paramus NJ. Buyers will be admitted free and sellers will be charged $3.00. There will be tailgating only; bring your own table. Thousands of spaces will be available. Talk-in on .79/.19 and .52. For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

LIMA OH
OCT 10

The Northwest Ohio Amateur Radio Club will hold its sixth annual hamfest on Sunday, October 10, 1982, at the Allen County Fairgrounds, Lima OH. Indoor flea market tables will be available for $5.00 for an 8-foot table or $3.00 for half a table. Tickets are $2.50 in advance, $3.00 at the door. Doors will open at 6:00 am and grand prizes will be drawn at 3:00 pm. Overnight camping will be available at the fairgrounds. Talk-in on .07/.67, .63/.03, .34/.94, and .52/.52. For more information, write NOARC, Box 211, Lima OH 45802.

BALTIMORE MD
OCT 10

The Columbia Amateur Radio Association will hold its 6th annual hamfest on Sunday, October 10, 1982, from 8:00 am to 3:30 pm, at the Howard County Fairgrounds (15 miles west of Baltimore, just off I-70 on Rt. 144, 1 mile west of Rt. 32). Admission is $3.00, tables are $6.00, tailgating is $3.00, and indoor tailgating is $5.00. Food will be available and prizes will be awarded. Talk-in on 147.735/.135 and 146.52/.52. For table reservations or information, write Sue Crawford, 6880 Mink Hollow Road, Highland MD 20777, or phone (301)-286-3805.

WAUKESHA WI
OCT 10

The Kettle Moraine Radio Amateur Club will hold its annual Ham, Computer, Video Fest on Sunday, October 10, 1982, at the Waukesha County Expo Center, Highways F and FT, Waukesha WI. Tickets are $2.00 in advance and $3.00 at the door. Tables are $3.00 for each 4-foot length; reservations will be accepted until October 1, 1982. Since all facilities will be indoors, the hamfest will be open rain or shine, beginning at 8:00 am. There will be prizes, food, commercial exhibitors, a "happy hour," and free parking. For table reservations, send a check payable to KMRA Club, PO Box 411, Waukesha WI 53187.

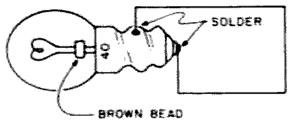
CHELSEA MA
OCT 17

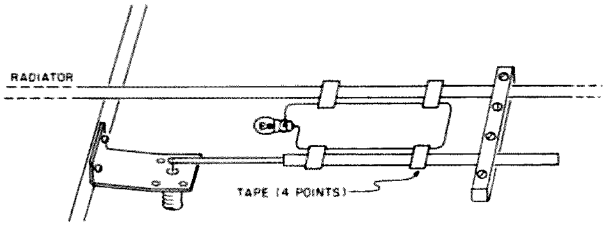
The 19-79 Repeater Association of Chelsea MA will hold its annual flea market on Sunday, October 17, 1982, from 11:00 am to 4:00 pm (sellers admitted at 10:00 am), at the Beachmont VFW Post, 150 Bennington Street, Revere MA. Admission is $1.00. Sellers' tables are $6.00 in advance and $8.00 at the door, if available. Talk-in on .19/.79 and .52. For table reservations, send a check to 19-79 Repeater Association, PO Box 171, Chelsea MA 02150.

CIRCUITS

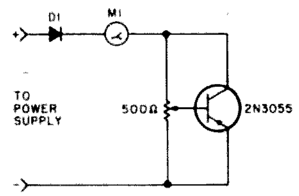
Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

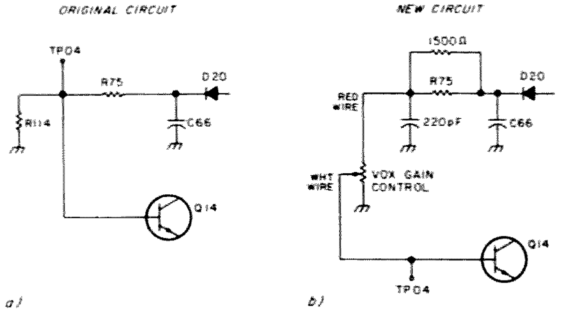




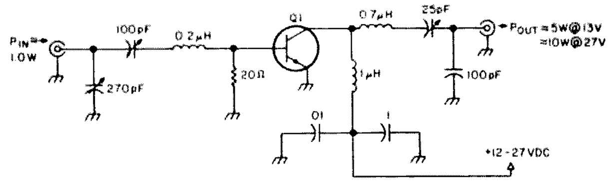
VISUAL ADJUST FOR GAMMA MATCH: In an emergency or when you don't have your swr meter handy, you can still adjust a gamma match with good results by doing the following: Make a rectangular "Hertz loop" (see diagram) by soldering a piece of solid hookup wire to a 6.3-V, 150-mA, no. 40 pilot lamp. You may use a socket if desired. The loop is the same height as the gamma and about half the width. If the exciter is QRP, it may be necessary to increase the width of the loop a bit. Fix it to the gamma with masking tape and excite the antenna with about 10 Watts (or enough power for the lamp to start to glow). Adjust the gamma for maximum brightness of the lamp. If the lamp becomes too bright, you may decrease the coupling between the Hertz loop and the gamma by bending one end of the loop slightly away from the match. Caution: Do not touch the antenna with the power on. After adjusting for maximum brightness, remove the loop and the antenna is matched. Even if you use an swr meter at the transmitter end of the scale, it may falsely indicate a perfect match with certain lengths of coax. However, if you also use the Hertz loop, it quickly verifies that the gamma is adjusted for maximum power transfer.—Jose Vicente PY2AUC, Campinas, SP, Brazil.



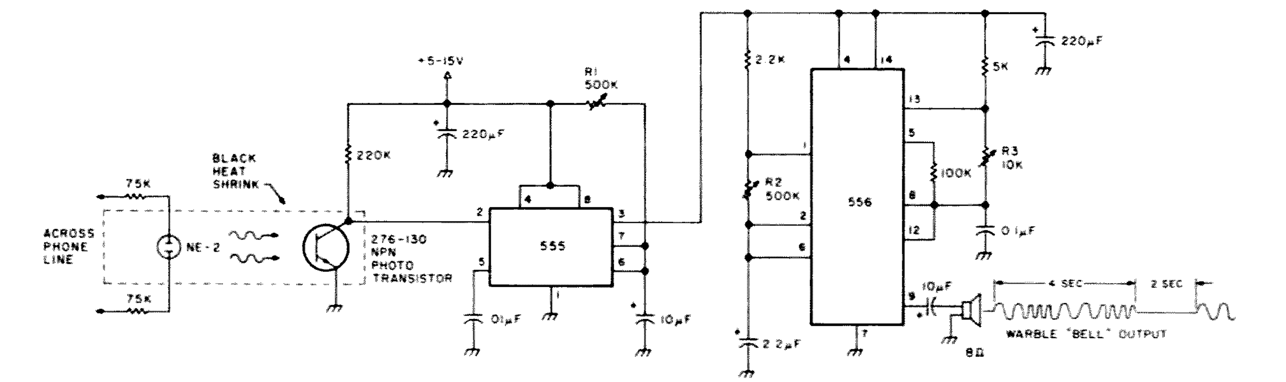
DUMMY LOAD FOR POWER SUPPLIES: The series pass transistor is used as a variable resistor and will handle up to 15 Amperes or 115 Watts. The base bias is set by the resistor so that the conduction can be varied. The transistor will get rather hot. It must be mounted on a heat sink and should have forced cooling if heavy loading is anticipated.—Glen Deibart, APO NY.



NOISE-BLANKER MODIFICATION FOR THE YAESU FT-707: Fig. (a) is the original circuit in which full gating is used. Fig. (b) shows the new circuit which employs variable gating on Q14, improving the suppression of ignition noise. I had no need for the VOX control, so I disabled it and used the potentiometer for the noise-blanker gate control. Results were very good; adjust the control until the ignition noise and strong adjacent signals disappear.—Carl Weiche W5NLB, Tulsa OK.



SIX-METER AMPLIFIER: This class C six-meter amplifier produces a respectable signal when driven with about one Watt from a military GRC or PRC FM transceiver or a conventional amateur transmitter. The CB transistor operates only slightly warm with two square inches of heat sink. The Q of the output network is 7 when operated at 13 volts. The input network Q is 3.5.—Al McKenna WB6BSP, Healdsburg CA.



ELECTRONIC PHONE BELL: The speaker emits a distinctive warble tone when ring pulses are applied to the phone line. Use this circuit as a remote bell or disconnect the phone's ringer for direct use. R1 adjusts the duration of the output; R2 and R3 control the tone's duty cycle and frequency. The transistor is a general-purpose NPN photodevice. The neon bulb and transistor are coupled with the heat-sink tubing to form an optoisolator.—John Mairs AA4DX, Springfield VA.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am looking for a schematic for a keyboard manufactured by Incoterm Corp., assembly 055-13-02-70REV. I am also looking for any information on how to interface this keyboard to a RTTY or microprocessor system.

I am looking for a schematic for a 1934 Philco table-model Type 89, Code 123, Ser. No. D-15143.

Charles Owens
Denbow Rd.
Durham NH 03824

I am looking for a Central Electronics 200-V transmitter in any condition or parts for the same.

Ted Wilson KA7LVT
12439 So. Giles St.
Las Vegas NV 68124

Wanted: OS8N oscilloscope, a Sencore TC28 tube tester hybridster, Ameco R5 receiver, and a Knight Kit vfo. Please state price and condition.

Kevin Neal
Rte. A, Box 221A
Flippin AR 72634

Looking for equipment donations to help initialize a ham club station at a recently-opened veterans home. All donations accompanied by a note giving approximate values will be accordingly acknowledged since they are tax deductible.

David Basham AE8Y
Chief, Social Services
Barboursville Veterans Home
512 Water St.
Barboursville WV 25504

Schematics or manuals on the following would be appreciated:
- Hallicrafters SX 104-30-50MC receiver.
- Precision Applications E400 series sweep generator.
- Knight capacitance checker.
- Tektronix 541-535 O-Vert plug-in.
- Military OS-8U oscilloscope, PS1J power supply, and P1B2X8J oscilloscope.
- Electalarm Model ID60 alarm by Nuclear Electronics Corp.
- American Telephone alarm, Model AE 202UL, c/o ATA Controls Systems.
- Sears Micromatic IC cassette tape recorder.

Costs for postage and/or copying will be paid, but let me know them first.

Kevin Neal
Rte. A, Box 221A
Flippin AR 72634

I need a schematic and manual for the IC-2F VHF 2-meter transceiver and a schematic for the IC-3P power supply 3375, made in 1970.

Harold Nelson WB9QMX
401 East Wisconsin Ave.
Silver Lake WI 53170

I need the dimensions for the CW radials for the Hy-Gain 18AVTWB antenna.

Sam Creason K6EW

WILL HEARD BE HEARD?

A DXpedition to Heard Island, in the southern Indian Ocean, nears reality. At the International DX Convention in Visalia, California, last April, Ian Hunt VK5QT announced tentative plans to activate this rare radio location. In the months following, the details (and especially funding) started to fall into place.

Heard Island is a small rock sticking out of the frigid seas not far from Antarctica. To locate Heard on the globe at your neighborhood library, put your finger on Saskatoon, Saskatchewan. Now find the diametrically opposite point on the globe, the spot antipodal to Saskatoon. Unless the manufacturer's logo is covering it up, you should have found Heard. Getting radio equipment and operators to Heard won't be so easy.

Heard sits in the middle of some of the worst weather in the world. Temperatures as low as −60° and winds in excess of 300 km/h have been recorded on the coast of Antarctica, the nearest significant land mass to Heard. Far from shipping lanes and lying in the dreaded wind belt that sweeps around Antarctica, Heard is about as isolated and inhospitable a spot as one can find.

So why are amateurs going there at all? Several mountaineers plan to scale Big Ben, Heard's 2700-meter high, ice-covered volcano. Splitting the costs with the mountaineers in return for providing top-notch radio communications in case of emergency puts the Heard Island DXpedition into the realm of the possible although costs for the radio part of the trip alone will top $30,000.

The International DX Foundation and the Northern California DX Foundation have offered $10,000 each toward the trip, and the Wireless Institute of Australia will provide four stations and has pledged $7,000, which it hopes to raise through donations.

The DXpedition is under the guidance of the DX Chasers Club, a Western Australia group, with Gordon Nichols VK6XI as chairman. Two or three hams will spend the month of February, 1983, on the island, while the mountain climbers do their thing. Since there is absolutely nothing to do on Heard except try to keep warm, the hams should have plenty of time to operate.

The two DX foundations will finance their contributions directly from their treasuries, but they hope to gain new members and receive extra contributions for the effort. The International DX Foundation asks for $25.00 for a one-year sustaining membership (write PO Box 117, Manahawkin NJ 08050). The Northern California DX Foundation (PO Box 2368, Stanford University CA 94305) also will accept Heard funds. But the official Heard Island account is care of the Wireless Institute of Australia, PO Box 10, West Perth 6005, Western Australia.

Incidentally, the International DX Foundation gained quite a bit of notoriety recently with an up-front article in *Time* magazine (May 3, 1982, page 7). Written by Navassa DXpeditioner Ed Magnuson W2IJB, a *Time* staffer, the article brought the world of DXpeditions to 1.6 million readers. The highly successful KP2A/KP1 Navassa trip bodes well for the success of the Heard Island trip. We'll have more on both the Navassa trip and the IDXF in future columns.

Assuming everything stays on track, VK0HI should be on the air early next year. We'll be providing more details on Heard and the DXpedition plans in coming months, but meanwhile, why not send a donation to one of the groups above?

One callsign which will be conspicuously absent from the VK0HI pileup will be that of longtime DXer Jesse Bieberman W3KT.

JESSE BIEBERMAN W3KT

The DX fraternity was greatly saddened to hear of the death of one of its most valued members, Jesse Bieberman W3KT. Jesse passed away on May 28, at the age of 77.

A native and longtime resident of Philadelphia, Jesse displayed an undying dedication to two of his loves: teaching and ham radio. He worked with students both in his job as teacher and in ham radio, founding the school radio club as well as staying active in the prestigious Frankford Radio Club.

In his later years, Jesse served amateur radio as Vice Director of the Atlantic Division of the ARRL for ten years, and then, after 1980, as Director. He attended the IARU conference in Lima, Peru, in 1980 as a member of the Foreign Affairs Committee of the ARRL board, and he served as the board liaison to the DX Advisory Committee.

Jesse's radio career spanned more than six decades, beginning with his first license in 1920. His longtime dedication to DX kept his call on the top of the DXCC Honor Roll on both SSB and Mixed. And when the CW DXCC award was announced, Jesse was ready. He earned CW DXCC Number 1 in 1975, at the age of 70. He also was an active contester, consistently operating for the Frankford Radio Club's winning efforts.

Jesse was best known for his efforts in QSLing. He served as the volunteer manager of the W3 QSL bureau for 33 years, sorting other amateurs' cards and making sure they got to their proper destinations. And in that 33 years, not one amateur officially complained about the bureau, an absolutely remarkable record given the notorious impatience of DXers!

But Jesse did more than handle the incoming cards for hams in the third call area. He shared his years of QSLing experience with any amateur. Jesse ran the W3KT Outgoing QSL Service, the most respected DX QSL forwarding service anywhere. For just a few cents a card, Jesse would locate the best possible QSL route for a given station: direct, through a manager, or whatever. He forwarded your card with others for the same station, with return envelopes. When the cards came back, he distributed them via the incoming QSL service, keeping the costs of the service within the reach of every DXer. Jesse knew all the tricks, all the ways to increase QSL returns.

The W3KT QSL service is now closed. Those cards in the pipeline will be forwarded, but no new cards are being accepted. Jesse's shoes are just too big to fill.

But the DX world has lost more than the best QSL service; it has lost a dedicated DXer who unhesitantly helped others, a fine example to new and experienced operators alike, a man who gave freely of himself so that others could enjoy the hobby that he loved so much. We have lost a good friend. We will miss you, Jesse.

CHINA UPDATE

China continues to make DX news. Both Chinas, in fact. More details of the future of amateur radio in the People's Republic of China leak out around the now-tattered bamboo curtain, and Tim Chen's QSL manager, K2CM, provides some additional details on BV2A/B.

BY1PK has been on and off the air since the first legal operation from mainland China in 30 years began earlier this year. Operator training continues with materials provided by various amateur radio organizations, including the ARRL. The operators will soon return to their homes, carrying with them the experience gained in Beijing. Sometime in the not-too-distant future, these new ops will activate more stations in China, and BYs will be heard more than sporadically.

Meanwhile, bootleggers have been enjoying open season with the BY1PK callsign. The Chinese operators have been deluged with QSLs from well-meaning amateurs who worked someone signing BY1PK. Most of the stateside hams received very nice postcards from China in return for their QSLs and IRCs, but, alas, not a single QSL card. The few hams lucky enough to catch BY1PK on the first run (mostly JAs) can justifiably treasure their colorful cards.

The BY1PK operators stayed on CW, often haunting frequencies 30 kHz up from the bottom of the band, especially on 15 and 20 meters. A straight key and a request for a full QSO with exchange of names and QTHs was typical. QSLs with IRCs to Box 6106, Beijing, People's Republic of China, have gotten a re-

sponse. How soon will BYs be as prevalent as JAs? Not right away, but BY won't be on the top of the most-wanted list for much longer. Meanwhile, there is always the "other" China.

Charlie Moraller K2CM was kind enough to share additional details about Tim Chen and BV2A/B. First, those calls are assigned to the China Radio Association. The club station is quite distant from Tim's home QTH, which limits activity, but Tim continues to be the only member of the Association with permission to operate. The frequent typhoons which rip through the *region* force dismantling of the yagi every year. The normal yagi emits a far better signal than the dipole used in typhoon season.

Charlie says that Tim wants the QSOs from BV2B QSLed direct to Box 101, Taipei, Taiwan, Republic of China. K2CM is the QSL manager for BV2A. Tim's choice. QSL BV2A via K2CM, 70 Silverbrook Road, Shrewsbury NJ 07701.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Sometimes you just can't win. I mean, I try to plan out this column for months ahead, and then you all go and respond to me, and now here I am with a ton of mail on my desk! Oh well, one of the things I most enjoy is answering questions here in the pages of *73*, so I guess this month I'll plunge right in.

Interest in applying microcomputers has never been higher. Dennis Adamkiewicz KA8ETB, from Cleveland Heights, Ohio, drops a line that he is trying to put his home-brew 6803/6847 system up onto RTTY. This sounds like a reasonable combination, and with suitable software should be just the ticket for a silent terminal. The programs published in this column a few years back can provide a starting point for such software, and I am sure that the sequence we are going through now will also be helpful. Let us all know how the project progresses, Dennis.

Chuck Evola is another 6800 buff, but this time with the old Altair 680b. A few months ago, I noted in this column that Chuck was trying to get his system up on RTTY, and the next thing he knew he was exchanging software and printing RTTY using a modified version of the receive program from this column. Chuck sends along his version. I have cleaned it up a tad, and it is printed here for all you 680b fans out there.

Another question posed by Chuck is about a technique to prevent printing unless "true" RTTY is present. I will suggest at this time that such a technique is indeed feasible, using multiple-sampling methods. The receive routine I will develop for the terminal described in July (to continue next time) will use just such a technique, so don't go away.

While we are on the subject of 6800s, Keith Diehl AL7CC up in Anchorage, Alaska, writes of the availability of the A.M.I. 65051/68051 ACIA chip. He notes that this 6800-compatible chip can be interfaced much as the more-common 6850 ACIA, but that it is able to handle five-bit words with a 1½-bit stop pulse. Sounds interesting, Murray or less! Wonder if anyone else is using this chip.

Letters with lists of questions sometimes arrive, and such is the case with a note from Todd A. Lefkowitz, M.D., an opthamologist who enjoys shortwave listening with a special ear towards utilities DXing. Todd's first question is the killer: "Which decoder do you recommend?" I really cannot endorse anyone's RTTY demodulator, Todd, partly because I want to be fair and partly because I have not seen everyone's in use to compare. I can tell you that, in general, you get what you pay for, and that the available low-end demodulators, such as the iRL FSK-500 and Flesher TU-170, provide good performance at an attractive price. Moving up to units such as the iRL FSK-1000 or one of the Hal units may be needed if you need some bells and whistles, but I suggest you write for data sheets from several of these companies and compare specs for yourself.

Two related questions Todd poses are about a source for RTTY frequencies other than Tom Harrington's book reviewed here last year and other sources for Oliver Ferrell's RTTY frequency guide. I am afraid that if Gilfer Associates, the publisher, has indicated to you a lack of copies of the Ferrell book, then you have shot the wad. I know of no other source. The Harrington book, which is available from the *73* Radio Bookshop, remains an excellent (and to my knowledge, the only such) guide to utility and other RTTY signals.

Todd's last question is a common one which I have fielded any number of times. He asks for books or magazine articles on RTTY principles and basics. Unfortunately, there is no book currently available which covers RTTY basics with modern techniques. What is around are ten-

Program listing.

and twenty-year-old circuits and books which predate ASCII and much other recent development. Hopefully, this is a situation which will be soon corrected by the gang at *73*. As far as magazine articles, you are reading the most consistent source for RTTY information for the last five years. Within the covers of this magazine, I am sure you will be able to find the answer to many, if not all, of your RTTY problems. If you have specific questions, drop me a line and I will see what I can do to reply in a future column.

Carl E. Nelson KI0H, in Blaine, Minnesota, touches base with his recently-developed interest in RTTY. He wants to put an ASR-33 Teletype® machine on the air and is looking for plans for an AFSK generator and demodulator. He also is interested in ASCII-to-Murray (Baudot) conversion, for use on five-level circuits.

A similar question comes from Dr. William W. Fulcher, Jr., N4WF, over in Hendersonville, Tennessee. Bill is looking for help in wiring a Teletype Model ASR-28 he has obtained for amateur use.

Well, gentlemen, and ladies in attendance also, many of these questions have been answered in previous editions of "RTTY Loop." In the five years of this column, I have covered the hookup of many types of Teletype machines and have presented various circuits for transmitting and receiving. At present, there is no compilation of this material available. Hopefully, something of this kind will be available in the not-too-distant future. If you are interested, drop me a line and let me know what you would like to see in such a publication.

A gentleman who makes his wants clearly known is Larry Marcus W5MDT, from Piano, Texas. Larry is looking for a book or source that will give a "comprehensive understanding of the various computer software available as well as the dedicated machines" that he sees advertised. The biggest problem with this, Larry, is the huge variety of stuff. It would be difficult to assemble a collection of all that is out there in one place to "A/B" compare it, and short of such a direct comparison, any presentation is bound to be biased. Nevertheless, I would refer you to the many articles presented here in *73* and in our sister publication, ***Microcomputing***, for some help. I have tried to review whatever I have been able to get ahold of, and in the past have looked at several systems. Many manufacturers, however, are less than willing to submit their systems for criticism. Again, I am sorry, but to the best of my knowledge, no book is available that would answer your need specifically.

Speaking of manufacturers, I have a note here from Bob Pearson KH6AKW, who runs an outfit called Hawaiian Computer Software. Bob has a program for the Ohio Scientific Superboard II that enables that computer to run Murray and ASCII with a variety of features and enhancements. It looks interesting, although I am unable to try it out, for lack of a Superboard II! A random thought which occurs to me is that the Superboard II is a 6502-based computer, much as the Apple and Pet. Wonder if some conversion would be possible to these systems? Might be worth looking into, Bob. Anyway, if you are interested, drop Bob a line at Hawaiian Computer Software, 99-060 Lohea Place, Alea HI 96701. Make sure you mention ***73 Magazine's*** "RTTY Loop" in your note, OK?

More next month, with a return to the super 6800 RTTY terminal we have been describing. Remember, if you want a question answered here in the column, send it to me at the above address. If you would like a personal reply, you must enclose a self-addressed stamped envelope. I try to answer all questions received, but I do have quite a backlog. Just be patient, and keep watching "RTTY Loop."

REVIEW

THE INFO-TECH M500ASR

This is not really meant to be a "product review" but a down-to-earth look at some of the excitement and problems a new product can bring and the way it affects the health and well-being of the owner of a new piece of gear—especially if it is of new design.

The Info-Tech M500ASR is a state-of-the-art communications terminal for use in the transmission and reception of RTTY in the ASCII and Murray (Baudot) codes as well as for sending and receiving Morse code. It is a microprocessor-controlled unit based on the Fairchild F8 (3850) and has 20K of memory which is divided up into 8K ROM, 8K RAM, and 4K video RAM. There is an option that allows the addition of 10K of RAM for the mailbox systems.

The system consists of three major units: the mainframe, which houses 95% of the electronics, the keyboard, which is connected to the mainframe via an umbilical cord, and the monitor, which is a Sanyo VM4512, 12-inch black and white monitor.

Features

The M500ASR will encode and decode ASCII up to 1200 baud and Baudot up to 100 baud. In the ASCII mode at 110 baud, it uses an eleven-unit code which consists of 1 start bit, 7 data bits, 1 parity bit, and 2 stop bits. When using 150 to 1200 baud ASCII, the M500ASR uses the ten-unit code which is the same as the eleven-unit code except there is only 1 stop bit. The use of parity is also keyboard-selectable from odd, even, or none. When none is selected, parity is marking. In the Baudot mode, the M500ASR uses the standard 7.5-unit code. In the Morse mode, it will send and receive CW from 5 to 100 wpm, with auto-tracking on receive.

There are five types of transmitting modes in RTTY: letter mode, word mode, line mode, buffer mode, and clocked mode. In the letter mode (or character

mode, as it is more accurately described), each letter is transmitted as it is entered from the keyboard. In the word mode, the pre-typed word is sent only after the space bar is entered. In the line mode, an entire line of text is transmitted only after the return key is depressed. In the buffer mode, pre-loaded buffers are dumped on command.

Of all the different modes that are available, the clocked mode is the most unique. The output is slowed to a speed that depends upon the setting of the clock output value. It allows the transmitted character output to maintain a constant rhythm that gives the station on the receiving end the illusion that you are typing at a smooth and even rate. In selecting clock values, a selected value of 1 would be full speed and 9 would cause the output to be one ninth the normal rate.

The M500ASR has several different message systems available. There are ten programmable messages of up to 144 characters each. Each message can be sent separately or the entire contents of messages 0 through 9 may be linked to allow up to 1440 characters to be preloaded. This is especially handy for "brag tapes" or message handling. There are two types of ID messages available. One is CW ID only and the other allows a RTTY message to be incorporated into the ID. This message is preprogrammable and allows you to ID in RTTY then CW. After CW ID, it will go back to the original mode and speed automatically.

The Modem

The modulator/demodulator system (modem) of the M500ASR uses an envelope detector tuned to a center frequency of 1000 Hz for the detection of Morse code. However, as with any other system that receives Morse code, it must receive decent CW. If you try to copy someone who uses his own brand of spacing (the type that makes Sam Morse roll over in his grave), you will get nothing but garbage on the screen. However, if the transmitting station is using an electronic keyer with proper weighting or, better yet, another computer, you will get 100 percent copy (depending on band conditions and QRM, of course).

In the RTTY mode, a three-shift active filter demodulator is used for all Baudot speeds and 110-baud ASCII. The shifts are 170, 425 and 850 Hz. The 425-Hz shift is really handy for those serious SWLs who love to see the news before anyone else does, or get the latest in the weather directly from the National Weather Service in Kansas City. A separate active filter is provided for ASCII speeds from 150 to 1200 baud. The RTTY tones are provided in several different ways. There is a three-function generator used to generate the audio tones that are fed directly into the mike of your rig. In addition to AFSK, there are FSK, inverted FSK, and RS-232 keying outputs.

For automatic operation of the keying circuit of your rig, there are several different push-to-talk (PTT) lines available. Now, while we are on the subject of AFSK and FSK, some of you old-timers will be saying, "He should tell new operators to use FSK only, because AFSK causes adjacent channel splatter and unnecessary QRM." Well, let me say this: I have been using nothing but AFSK for over a year and have not run into any problems yet. The catch is that you must be very careful not to overdrive your rig and must check your outgoing signal regularly for flat-topping and distortion. Should you find the AFSK generator is flat-topping, splattering, or distorting, the level can be lowered from the factory-set value of 1.5 volts.

Hard Copy

If you decide to become a "green key," at some time you will find the need to have a hard copy of what you have received. (If for nothing else, just to show your friends the pictures of the nudes being sent on 14.0895 MHz.) This is one area where the M500ASR really shines. There are several different printer inputs and outputs available, including a fully-isolated loop for those of you who still insist on using a mechanical monster such as a model 15. For the newer printers, RS-232 and MIL-188 are available. But that's not all. The printer outputs are fully regenerated. You can copy 110-baud ASCII on your 45-baud model 19 or 1200-baud ASCII on your Epson set at 300 baud without the need for external converters.

There is a limit to this. If you try to copy 1200-baud ASCII and print it on a printer set at 300 baud, the printer buffer on the M500ASR will fill up, overwriting text that was already in the buffer. Also, let me remind those of you who are into SWLing that what you copy is for your eyes only. Don't make the mistake of printing out a long story from the AP or UPI and showing it to your neighbor. If you do you will be violating FCC regulations.

Tape Interface

RTTYers tend to be very long-winded. This is where a cassette interface becomes very handy. Most RTTYers have compiled brag tapes that give a rundown of their station equipment. Some include personal information, general info about the XYL, the rug rats, dog, cat, job, etc. Most of the cassette interfaces in use today are really nothing more than a few simple connections which allow you to record and play back through your terminal.

The M500ASR cassette interface is more like the type of interface you would find on a personal computer. It actually outputs data in blocks using Kansas City standard tones. The data is loaded and stored in fixed blocks of 1008 characters. Each data block is preceded by two groups of synchronizing leaders and followed by a group of end-of-block transfer codes. The codes are automatically generated when a recording is made, and tested when it is played back. When the cassette load or dump command is entered, the cassette motor control will turn on, starting the cassette recorder. Then the first synchronization group will be sent. After the recorder comes up to full speed, the second group will be sent followed by the data block and end-of-block group. After the end-of-block group is sent, the cassette motor control will turn off.

Because of the way the tape is formatted, it is not necessary to start the tape at a specific point when playing back or loading data. Also, all other functions may continue in normal operation as long as you do not try to access the buffer where the tape operation is originated.

In actual operation, I have found that the tape interface is a handy device, but it is not too well suited for use in running brag tapes or picture tapes due to the limit of the buffer. What it will allow you to do is to make a tape of your general operating parameters. Then all you have to do is turn the power on and enter the cassette-load command. While the cassette interface is loading your CQ message, ID, CW ID, Sel-Cal codes, and WRU answer codes, you can drink a cup of coffee while the machine does all the work.

Screen Options and Mailbox

The M500ASR has a "split screen" which divides the transmitted text and received text, both of which are displayed at the same time. The upper portion of the screen is the received text and is brighter in intensity than the lower, which shows the transmitted text or the text entered into the transmit buffer.

The system uses a 25-line by 72-character format of which any number of lines from 2 to 15 can be assigned to the transmit buffer. The bottom (25th) line is reserved for the status line which shows the current operating parameters of the unit and the time and date in local or Zulu time.

The receive video has word wraparound, a feature which prevents the unit from cutting off a word of 15 characters or less at the end of a line. When operating in the word or line mode, the transmit video area has the same feature. The system uses dual cursors. One, known as the keyboard cursor, indicates where on the screen the next character entered from the keyboard will be placed. The other cursor, called the transmit cursor, shows what character is next on line to be transmitted. This allows you to see how far ahead of the output you are when typing into the buffer and serves as an indicator of the number of characters which remain to be transmitted.

There are several keys available to the operator of the M500ASR. Along with the CQ and DE keys, there is a break key which, when depressed, causes the RTTY outputs to remain in the mark condition. When operating in the Morse mode, it causes the transmitter to be turned on. There is a run/load key which

controls the transmit buffer output condition. There is a repeat key which, when held down in conjunction with any other key, will cause that character to be repeated until one of the keys is released. The blank key causes the keyboard cursor to move back one space for each time it is depressed, up to the beginning of the line. There is a reset key which clears all of the RAM and initializes the operating parameters and causes a self test of the various segments of RAM. For Morse operation, there are special keys for AR, AS, BK, BT, SK, "Attention," and "Understand."

What do I do if I make a mistake when I am loading a message into the transmit buffer? Well, with the M500ASR's powerful editor, all you do is enter a few simple commands and, at the stroke of a key, you can delete a character, insert a character, or insert a string of characters. To edit text that has scrolled off the transmit video screen, you must enter the receive area buffer editor mode. Then you can edit the text in the same manner as you would when in the transmit buffer editor. The operation may sound complicated but it is not. The dual editor is a very powerful and extremely useful device. I have typed out several letters, and I even wrote this article using the M500ASR as a word processor.

I mentioned a mailbox option that is available for the M500ASR. I operated the system with the mailbox option, and, to be completely honest, I would not call it a mailbox. Generally, you think of a mailbox as being an electronic depository for the operator to receive messages while he is away from the shack. In reality, the M500ASR mailbox allows only others to send and receive messages. It gives stations total and complete control of the system. They can list a directory of messages in the mailbox. A station can call up a selective directory that lists only those messages that are for him. He then can read those messages and erase them. It really works well for other stations but it serves no purpose for the owner of the system.

The owner of the system cannot read a message or write a message for someone else. In fact, he cannot use it at all, because when in the mailbox mode, the keyboard is completely locked out. The only way to remove the system from mailbox operation once you are in that mode is to press the reset key or turn the power off. It is, in effect, a "blind mailbox." This would be a nice option for a RTTY repeater.

Problems

Murphy's law states that what can go wrong will go wrong, and believe me, for a while I thought I was Murph's stepson. When I traded my M200F and M300C for this brand new top-of-the-line system, I was, to say the least, very excited. I never had one bit of trouble with the other system, but when I hooked up the new system things started changing rapidly. During the first day of operation, the system showed some very strange and erratic behavior, bordering on being schizo. I had a choice. Either I was becoming senile (at age 28) or the microprocessor had a mind of its own.

The mark tuning LED went first. Then the system started refusing commands from the keyboard. Steadfastly, it ignored everything, while the colon on the block winked merrily away. A phone call to Info-Tech confirmed my suspicions: They were having problems with the programming of the ROMs and knew how to fix it. So, back to the factory it went. (Let me point out that I got the fourth production unit off the line and was really not too concerned with the problem. We all know that when something is new it is subject to several attacks of Murphy's law.)

Ten days later, the dust was barely settling in the tracks of the UPS truck when I had the system back on line. What happened now? Nothing happened. Murphy struck again. Now I am starting to have some second thoughts. Oh well, a phone call produced some reassuring sounds on the other end, and it was back on the road again for my M500ASR.

Like clockwork, ten days after I returned the unit the second time, T.J., the UPS lady, returned with my M500ASR. This time she did not even get a chance to get out the door before I had the unit hooked up and the power on.

Did it work? Well, it worked for a while, anyway. The mark tuning LED was fixed and everything seemed to be okay for about 15 minutes. And then? Data started jumping around to weird places. The entire screen filled with characters and started an endless scroll to oblivion. Bits and pieces from the recallable messages were popping onto the screen out of nowhere. Every time I tried to operate in the load mode, the system would try to send the status line over and over again.

I would hate to be on the receiving end of the phone call that would result from a problem like this. Luckily, John, at Info-Tech, had some more very interesting sounds to make. I think he could have been a politician.

A Short Time Later...

Someone is knocking on my door. Oh! "Hello T.J., I see you have a package for me. Great! It's my brand new (rebuilt) M500ASR. Thanks, T.J., see you later." As she shut the door behind her, I made a mad dash for the bench and started hooking up the unit. Let's see now. Power on. Looks good so far. Monitor on. All systems go. Status line normal. I want to assign four extra buffers to the transmit buffer, so I depress the SHIFT and CTRL keys at the same time and enter XB-4*. Yep, it works. I start tuning around the band, signals everywhere. Let's see, there's a strong one. It's 6D5M, with a nice signal in here calling CQ. I answer him, and we have a nice chat. Well, everything seems to be working OK. Maybe it's fixed.

Did you ever feel like you were Charlie Brown trying to fly a kite? You know, when the kite-eating tree always devours his pride and joy. Well, you can't blame the tree, it's probably hungry. Gremlins are like that, hungry all the time. They need three squares a day of silicon.

The same problems were there and I was getting a little tired of sending this system back to the factory. I saw a trend developing. After a long discussion with John, he said that he would send me a new set of EPROMs with some of the revisions to the program on them.

Even Later...

Someone is knocking on my door. "Hello, T.J., how are you doing? I see you have a package for me. Thanks, T.J., see you later."

Ten minutes later everything is hooked up and ready to go. What's that noise? I still hear little grumbling sounds. Must be my imagination. Power on. Everything looks good. Status line normal. Add four buffers to the transmit buffer. All systems go. I start tuning around the band. Wow! A 25 over signal. Its HH2CL with a great signal in here. Solid copy. Well, how about that, everything seems to be working fine. That makes the final score Info-Tech 1, gremlins 3. Not bad for a new player on the team.

One week later the battle cry of gremlins is loud and clear. They lost the battle, but the war is not over. They attack from all directions. The treaty is broken. Charlie Brown has better luck than this. Okay now, count to 10, stay cool, be calm, don't get excited. I am sure there is a logical explanation for this.

After some lengthy discussion with John, he decides to send me a new set of 2716 EPROMs and a new set of RAMs, on the thought that one or more of the RAMs could be bad. Well, at least it is not so bad this time. I can still operate RTTY while I am waiting for the new parts. The system acts only a little screwy.

Five days later T.J. is back at the door. After I scribble my name on the necessary form, not even the Roadrunner could catch me as I smoke the trail between the door and the bench.

It took longer this time, but two weeks later the gremlins were at it again. This time I think they are in for the duration. They are doing things I have never seen before. They are even attacking the keyboard, making some of the keys operate funny. I think this unit is jinxed.

Back on the phone with John. (I think I will put in a WATS line.) We discuss the problems and come to the conclusion that it would be best to send me a brand new system.

Three days after I shipped the unit back to Info-Tech, I called John to follow up and see that the unit had arrived. Indeed it had, but it did not make the trip in too good a shape. It seems as if UPS bounced it around a little and reduced it to a metal and silicon junk heap. Don't worry, I had it insured. John informed

me that they had already shipped me a new system and he would take care of the insurance claim from that end.

Murphy Lives!

Nothing is ever as simple as it sounds. Three days later, T.J. left a package for me on the door step. Imagine my dismay when I saw a yellow damage tag on the package. I thought they had damaged my new unit. Upon opening the package, I found it was the old one. Old Serial Number Four! Pieces of M500 were stuffed in the box. Great! What now? Out to the shack to call John and find out what is going on.

When I told John what had happened, the silence on the other end was deafening. His first words were "Oh, boy!" Then, after we discussed what had happened, he told me he would call me back and let me know what to do with the old one. In the meantime, my new system should be there the next day.

Here comes T.J. up the drive, and about thirty minutes later I had the new system (Serial Number 25) up and running. Everything was doing what it was supposed to do, and doing it well. And now that I had operated a fully-functional system, I realized that it was worth the time and trouble. Info-Tech has made a great advancement in the state of the art of RTTY.

John tells me that they want to put the old unit to the torture test and see if they can run the resident gremlins off. I wish them all the luck in the world. But right now I have to get dressed as T.J. and I are going to dinner and a show to celebrate.

The M500ASR (with 12" monitor) has a list price of $1475. A memory-expansion board with mailbox option costs $180. For more information, contact the manufacturer of Info-Tech equipment: *Digital Electronic Systems, Inc., 1633 Wisteria Court, Englewood FL 33533.* Reader Service number 482.

THE MFJ CW COMPUTER INTERFACE

MFJ Enterprises has done it again. For about $70.00, you can obtain a compact (6" × 4" × 2") yet complete interface for receiving and sending Morse code with your computer. Of course, you must write the software. But at least the hardware problem is largely solved.

In this review I will discuss the various aspects of the MFJ-1200 with emphasis on its design, features, and limitations. I will also explain why an interface is needed. Finally, I shall supply you with a BASIC program to receive Morse code. In this way, you can try out your 1200 right away while you are developing more sophisticated software to suit your own application. And, if you are a Heath H-8 and H-89 computer owner and cannot wait to get on the air with your machine, write me. I have a good program at a reasonable price available separately or in a package with the 1200.

First of all, what do you need to use the computer to read Morse code? Essentially, you must solve two problems: the hardware interface and the software support. First, let's look at the hardware. Imagine if you can the audio output of a radio receiver tuned to a CW signal. If you view it on an oscilloscope, you will see a train of audio oscillations of various widths interwoven with periods of no output. Each packet of audio waves represents an audible tone and its width determines whether it is a dot or a dash. The times when there is no output are the intracharacter, intercharacter, or interword spaces.

You can draw a curve around each wave packet. This curve is constructed to be tangent at each local maximum (peak) of the audio oscillation and is called an envelope. Ideally, the envelope is a rectangular wave, but in practice it will have finite rise and decay times. Of course, what I am describing is nothing more than an audio signal modulated by a rectangularly-shaped wave of a much longer period. Typically, the audio tone has a frequency of 1000 Hz or a period of 1 millisecond. At 20 words per minute, the envelope is about 180 milliseconds in length for a dash and one third of that for a dot.

The computer wants only the envelope, or, rather, its upper or lower half. The audio is only a carrier, and the situation is completely analogous to AM modulation and detection. Thus, the CW detector must extract the envelope, shape and enhance it, and then present it to the computer at a compatible level. This is precisely what half of the MFJ interface accomplishes. The computer will see a series of logical highs and lows at its input, where the length of time between transitions represents a dot, dash, or space. It is now up to the computer to convert the digital information to readable text.

Take a look at the schematic design of the MFJ-1200, Fig. 1. Beginning at the audio input jack, we find a simple diode noise clipper followed by a two-stage, multiple feedback, bandpass filter. The calculated center frequency is 850 Hz and the 3-dB bandwidth is 175 Hz for each stage. The second stage also drives an LED indicator which blinks with the CW input and provides an indication of proper tuning. Following this is a simple diode detector with a sense switch, and this circuit precedes a second-order, VCVS low-pass filter with unity gain and a calculated cutoff frequency of 75 Hz. This additional filter takes out unneeded detection products. Next, a comparator circuit shapes the detected output to produce a rectangular wave with a fast rise time and to generate RS-232 levels. Finally, a transistor converts the RS-232 to TTL levels.

Using a function generator and an oscilloscope, I found the center frequency to be 860 Hz and the 3-dB bandwidth to fall in the 780-to-950-Hz range. My frequency meter does not allow resolution finer than 10 Hz, so these values are certainly in agreement. I also measured the

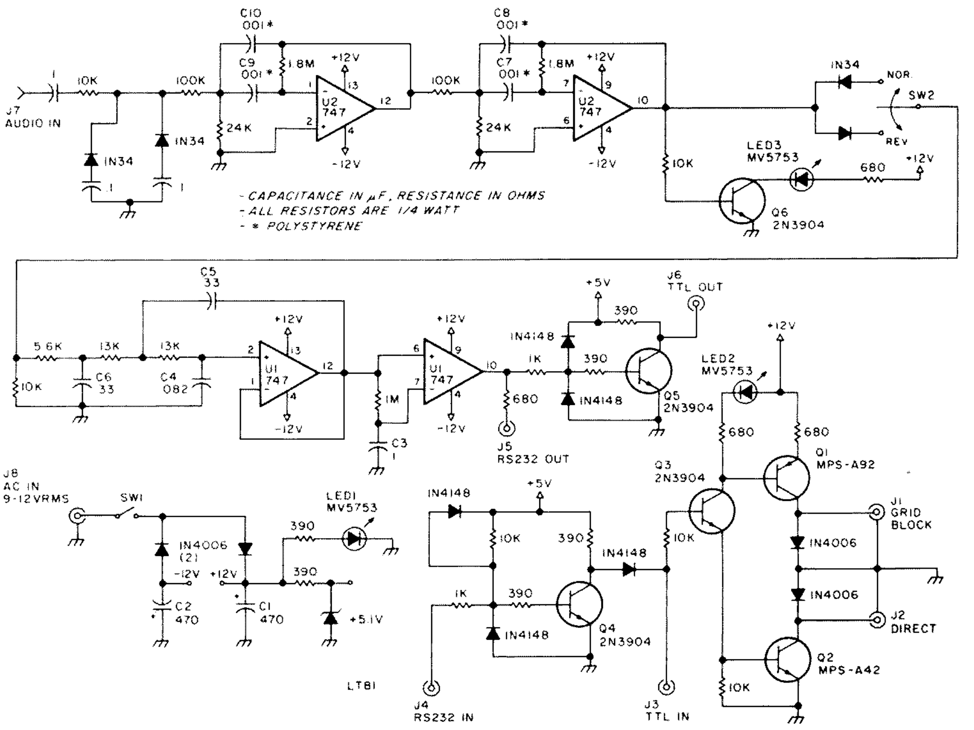

Fig.1. Schematic diagram.

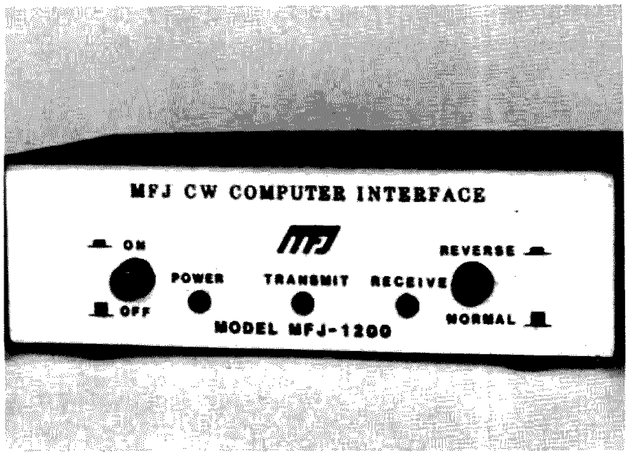

The MFJ CW computer interface.

low-frequency filter cutoff and read a 3-dB point of about 60 Hz. And, finally, I checked the rise time of the TTL output with an input code signal of about 22 words per minute and found it too short to measure.

The detector circuit is quite simple—a diode and a low-pass filter. It differs from the more frequently used 567 tone decoder. MFJ told me that they had experimented with the decoder but finally decided on the circuit described. It does, however, have a slight disadvantage, and that is that the bandwidth is rather strongly dependent on amplitude. I found that the higher the input amplitude, the wider the range of response. In contrast, a 567 will respond only over a width of about 14% of its free-running frequency once the input magnitude exceeds a certain threshold. But I have experienced no difficulty in actually using the 1200, and the documentation cautions the user to reduce the input until only the desired CW signal is activating the received-signal LED.

The MFJ-1200 will also key a transmitter. A transistor converts RS-232 to TTL levels, and a second transistor drives two high-voltage keying circuits. Unfortunately, the documentation does not give the maximum allowed ranges, but the catalog lists −300 volts at 10 mA and +300 volts at 100 mA. An LED glows when the transmitter is keyed. I have also used the unit to activate a battery-operated code-practice oscillator when running my AUTOSEND program. This program produces random or fixed-length code groups for learning Morse, and the 1200 not only allows me to hear the output but also to make practice tape recordings.

Let us now look at the MFJ-1200 from the user's standpoint. There are two switches on the front panel. One applies power. (The rectifier and filter circuits are inside; the power transformer is external and is built into the wall plug. Thus the unit expects 9-12 volts ac, and the application of dc can damage it.) The other push-button is a sense or normal/reverse switch. The output logic is reversed if this is pushed in. The usual convention is for a logic 1 to be an electrical low. However, with this switch the opposite sense can be chosen.

In addition to being able to accommodate various hardware/software arrangements, the sense switch has a rather unusual application. Some CW utility stations occasionally use frequency-shift keying. The various Navy stations on 8.090 and 12.135 MHz transmit with an 850-Hz shift from time to time. To take maximum advantage of CW FSK, you should have a RTTY modem such as the iRL FSK-1000. However, with the MFJ-1200 you can read either the mark frequency or the space frequency by changing the sense.

On the back are seven phono sockets and the ac-power connector. It is best to attach the audio input in parallel with the speaker line because the receiver volume control can be used to regulate the input level. This is important for readable code.

Two sockets give the detected output to the user at either TTL or RS-232 levels. These are the inputs to the computer. However, you cannot really use a serial input port even though the output from the 1200 is itself serial data. This is because Morse output does not have the form expected by the computer interface (UART) of start bit, data bits, parity bit, and stop bit(s). Rather, the software itself must perform as the UART. What the computer really needs is a one-line parallel port.

Many computers have parallel ports which usually operate at TTL levels, and it is quite easy to read them using assembly or high-level-language programs. Some computers have no parallel ports which are provided by the manufacturer. A good example is the Heath H-89, but even in this case it is easy to find input and output lines which are not part of the serial signal-in and signal-out paths. Many UARTS, such as the INS8250 and the 8251, provide several lines to control modems or other peripheral devices. For example, the 8250 has eight—four each for input and output. The output lines are located at port address +4 and are called Modem Control Lines. Similarly, the modem status lines at port +6 can be used for input. The 8251, while not quite so versatile, has one input and two output lines which can be found at port address +1. In some cases, the modem lines can even be used to generate interrupts. For more information, see your computer documentation.

The next two connectors on the MFJ-1200 are TTL or RS-232 inputs from the computer. The same remarks about output lines apply, and attachments should be made from a parallel port or modem control line and not from a signal-serial-output port. Finally, two sockets, one for direct and one for grid block keying, are provided. A subminiature phone jack is used for 12 volts ac.

To use the 1200, a CW signal is tuned until the received signal LED blinks brightly. The amplitude of the signal is then reduced until only the signal itself turns on the light. Too much drive causes the unit to interpret noise and adjacent channel interference as valid signals. The resulting output to the terminal is rubbish, with the periods between transmissions filled with Es and Ts. I found that with relatively careful tuning and regulation of volume, the received code was printed very accurately.

One of the most difficult aspects of using the unit is getting the volume level set properly to avoid false triggers and setting the center frequency accurately. The two go together since the detector allows a wider bandwidth with high amplitude. It would be a great help to have a tuning meter. One must balance economy with performance, of course, but it would be really useful to at least have a socket on the back where a simple meter could be connected. I found that after an initial setting, I could improve the accuracy by reducing the volume until the LED became quite dim and then returning for maximum brightness. Things do not have to be absolutely perfect; there is enough tolerance for minor errors, and the technique just described is adequate.

How well does it work? To find out, I tried it with several Morse programs and made a few heuristic comparisons. I also made a qualitative comparison with another CW detector—the iRL FSK-1000. Before you say that iRL makes only RTTY demodulators, let me remark that the FSK-1000 is an outstanding unit for CW, although for some reason the company never mentions this explicitly. Excellent filters, AM and limiter-detection modes, narrow bandwidth, and many other features make it a versatile unit for digital communications. I also point out that it costs eight times as much as the MFJ-1200, and its purchase for CW use alone is not sensible.

In all cases, we obtained good accuracy on machine-sent CW from the various utility stations. It seemed that a few more errors were made with the 1200 than with the FSK-1000, but the difference was not great. Amateur reception was not as good, but this has little to do with the characteristics of the CW interface or the program but rather with the nature of amateur communications itself. At this point, we should perhaps mention that computer CW may initially be a disappointment to some. Even very good Morse programs do not tolerate bad sending, and unfortunately it can be found everywhere. It takes an astute combination of eye, ear, and experience to use the computer in such code since a high percent-

CW SOFTWARE

The purchase of the MFJ-1200 solves a vexing hardware problem, but you still must write or purchase a program to fit your needs. You can test your new 1200 with a simple but effective BASIC program which I have shamelessly lifted from an article in *Kilobaud Microcomputing* by Robert W. Kurtz W8PRO (see References). Originally written for the Kim computer, I have tightened and modularized the code but left the basic technique intact. The original look-up table also has been modified by adding all Morse characters, and I have replaced the author's use of a "-" for a missing character by a null string. Finally, I have not hesitated to use the various features of MICROSOFT® BASIC such as integer representation and double-letter-variable names. However, the original variable names used by the author have not been altered. (For a detailed description of the theory of operation, see the original article. We will supply a copy for an SASE. If you are running HDOS, send us a disk and we will return a copy of the program as well.)

When you adapt the listing for your system, you may leave out the REM statements as well as those lines and comments preceded by an apostrophe. You can replace double-letter names by other variables. You also can omit line 240 if you do not have integer specifications, and you can omit the error-handling subroutine at 250. It is used to keep integer overflow from stopping the program. This will occur if the integer variables DO and DA are constantly incremented by noise without a chance to reset. It is not serious and it will never happen when receiving normal code.

The error routine also reminds you to set the input port parameters when you first run the program. Let us tell you how we connected the MFJ-1200 to our computer and this will explain the settings we used at line 790: 790 DATA &076, &040.

On a Heath H-8, there are several serial and parallel ports. Four of these are controlled by an 8250 UART. We attached the RS-232 output of the 1200 to the Data Set Ready (DSR) modem status line at a port addressed at 070 octal. DSR can be read by detecting the fifth bit at port address +6. Hence the input to the port must be ANDED with 00100000B (040 octal) to be read. This explains the values in the BASIC line above. The ampersand is MBASIC'S way of designating an octal constant. Equivalent decimal integers can also be used.

The program expects a value of A = 0 when the key is down. You will have to modify the program if the port read subroutine returns a different value for the same condition. Alternatively, you might be able to use the sense switch on the 1200 if the logic is simply being inverted.

If you have an H-89, use the port at 330 octal (0E8H). Attach the 1200's RS-232 output to pin 6 on the D-connector and ground to pin 7. (This is standard RS-232 protocol.) It is not necessary to attach anything inside the computer. For other machines, please consult your documentation. If you have a TRS-80, MFJ has a special version of the MFJ-1200 for you.

If you want to experiment with a sending program, you can try to use BASIC, but it will not be very satisfactory unless you can use character instead of line input. In Morse code it is better to send out a character as soon as it is entered on the keyboard. Microsoft's INPUT$ offers such a method. See also Reference 2.

Program listing.

age of what is typed out is either incorrect, badly spaced, or both.

On the other hand, keyboard and computer CW are received very well. It is a great pleasure to run along at 50-60 words per minute, and this is where this kind of digital communication method comes into its own. We have had some excellent QSOs at these speeds.

In conclusion, I found the MFJ-1200 a very satisfactory unit. It performs well, and its price is well within a range most of us can afford. it can open new worlds to amateur radio operators and to those interested in shortwave listening. It gives the computer user a new area of exploration. Despite its "ancient" (1836) origins, Morse code remains a viable and widely used method of communication, especially in the maritime services. I routinely listen to UPI news, read weather broadcasts and telegrams, and decode Russian CW in addition to our usual amateur activities. If you are interested in a list of utility stations I have received, or if you would like a copy of Cyrillic CW, write me for more information.

The MFJ-1200 can be purchased directly from *MFJ Enterprises, PO Box 494, Mississippi State MS 39762* for $69.95 plus postage. If you need a power supply, add $9.95. Reader Service number 483.

THE FLESHER TU-170 TERMINAL UNIT

After searching through several years worth of back issues of *QST* and *73*, it became clear that for receiving RTTY tones almost all amateur sta-

tions were using 170-Hz shift, and that there are in general two basic types of demodulators in use, the phase-locked loop type and the filter type. It also seems that fancier stations have autostart capabilities: the capacity to turn on an unattended TTY when a remote station starts sending.

Further reading disclosed that phase-locked loop demodulators tend to work great if there is no interference or adjacent strong signal, but that they tend to lock easily onto strong, adjacent signals, which could be a problem in HF work. Filter-type demodulators, however, are somewhat more immune to adjacent strong signals. Even further reading disclosed that the Flesher Corporation of Topeka, Kansas, marketed a TU using the filter type of demodulator, and that the unit had a tuning meter, autostart, and a built-in loop supply. Also, Flesher markets the unit in either kit form or assembled and tested. A phone call the next day to Topeka resulted in a small bruise to my VISA card, and the arrival one week later of my TU-170 kit.

For those readers who are accustomed to Heathkit® instructions, the Flesher unit will not exactly bring smiles of joy. The instructions are adequate, but the kit is best assembled by an experienced kit builder. The instructions are straight to the point and lump similar steps together. (For example, "Install all diodes" on board.) The kit builder working from a pictorial of the board first installs the jumpers (there are eight), then the diodes and resistors, and then the integrated circuit sockets. Although the kit does not include IC sockets, a slip of paper in one of the parts bags informs the builder that IC sockets are now supplied and that they should be installed instead of the ICs called for in the instructions. I installed the sockets where it said to install the ICs, and did not insert the ICs until after completing all soldering.

The Flesher TU-170 consists of one single-sided printed circuit board measuring approximately 6" by 6", a heat-sink plate which mounts to the PC board and in back of the front panel, and a Ten-Tec-type chassis/cabinet which consists of a U-shaped front panel/bottom-rear panel, a top, and two sides. Construction takes between 12 and 20 hours, depending upon your ineptitude. A small pencil-type soldering iron should be used, and care should be taken to minimize the heat, particularly around the front-panel switches.

A special caution should be noted about the front-panel switches. They are very inexpensive and are especially susceptible to heat damage. Being of frail plastic design, if too much heat is applied to the contact posts, the plastic body may become soft, allowing the contact post being soldered to move and the switch to become inoperative. If this should happen, as in my case, a call or letter to Topeka will result in a new switch arriving about one week later. Do not bother, as I did, to try to find a replacement switch around town. A search of Los Angeles found no suitable switches which would exactly fit the square hole in the Flesher front panel. The factory is very polite and helpful in such situations, but it does take about a week from the time they are notified to get a new one.

Other rules of kit building that one should observe include:

1) Follow the instructions!

2) After finishing the PC board, check each component for correct value and orientation, as well as for a good solder connection. Also check for and remove any solder splashes.

3) Do not rush!

4) Use a good wire stripper, not a pair of cutter pliers.

5) Do not rush; follow the instructions.

Assuming that you observe the above cautions, it is highly probable that a completed TU-170 will appear several nights after you started, along with some burn marks on several fingers.

Before discussing alignment, it is useful (as they say in the text books) to look at the Flesher TU-170 from the functional point of view. Fig. 1 shows a block diagram of the unit. It is divided into three major functional blocks: the demodulator with autostart and loop-keying circuitry, the modulator, and the power supplies.

With the exception of the autostart line-switching solid-state relay, meter, switches, jacks, and input/output terminal board, all of the circuit components are mounted on the 6" by 6" PC board.

Details of the demodulator are shown in Fig. 2. The audio input from the transceiver, containing the mark tone at 2125 Hz and the space tone at 2295 Hz, passes through the mark and space filters and is then rectified. The negative half of the filtered space signal or the

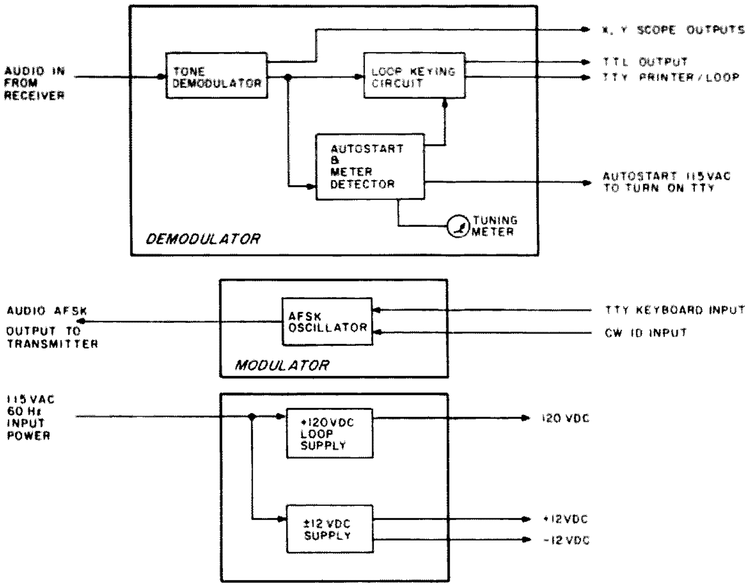

Fig. 1. TU-170 terminal unit functional block diagram.

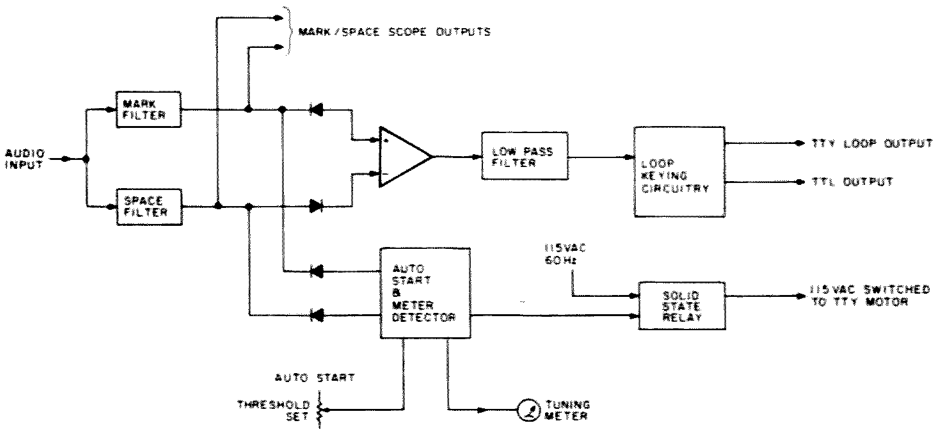

Fig. 2. Demodulator detailed block diagram.

positive half of the filtered mark signal then drives an amplifier either hard positive or hard negative. The output of the detector then is low-pass filtered to remove the high-frequency audio components, and then squared off and sent to the loop-keying circuitry. The loop-keying circuitry switches the + 120 V dc which runs the TTY printer magnets.

For computer enthusiasts, a TTL-level output is available. Also available at the mark and space filter outputs are high level signals (15-volt peak-to-peak) to drive the horizontal and vertical channels of an oscilloscope. The mark signal is normally applied to the horizontal channel, and the space signal to the vertical channel of the scope. These signals will provide a cross or crossed-ellipse pattern when connected to the scope when the RTTY signal is properly tuned.

The filtered mark/space signals also have their negative halves rectified and are fed into the autostart/meter detector. The front-panel meter will indicate maximum deflection when a signal is properly tuned. The autostart circuit will turn on 115 V ac through a solid-state relay when a RTTY signal is present. The 115 V ac may be used to turn on the TTY motor. A front-panel potentiometer allows the autostart detector to be set at any desired minimum signal level, thus avoiding activation of the TTY on noise or low-level signals. The transmit and receive modes are controlled by the Send/Rec switch on the front panel. A set of contacts on this switch sends + 12 V dc to the loop-keying circuit, thus preventing spurious output from the demodulator from keying the printer during transmit. A second set of contacts on the Send/Rec switch can be used to trip the push-to-talk circuit on the transceiver.

The TU-170 modulator generates the audio mark/space tones. Fig. 3 shows a block diagram of the audio modulator. The TTY keyboard contacts provide a switched loop voltage which, after going through the loop-keying circuit, provides a high- or low-level input to the modulator. The frequency of the modulator is generated by a 555 timer/oscillator integrated circuit. By changing the value of the resistance in the 555 frequency-determining components, either a 2125-Hz mark or a 2295-Hz space signal will be generated. A high input to the modulator will cause a mark to be generated, and a low input, a space.

For a space, the frequency is changed by a transistor and FET which switch a resistor in parallel with the mark-frequency-determining resistor, thus presenting a lower resistance to the 555 and causing a higher frequency to be generated—in this case, a 2295-Hz space frequency. For CW ID, a separate Input is provided which changes a capacitor connected to the 555, thereby providing for a 100-Hz shift for a key to send your call in shifted CW.

The output of the 555 is filtered through an active filter. A pot allows the filter to be centered and, therefore, equal amplitude on both mark and space signals can be adjusted. The 555 circuit and filter provide a very clean and coherent signal.

Alignment of the TU-170 is very straightforward. First the modulator is set to the correct mark and space frequencies. A counter is needed for this step. The mark is set first by adjusting a potentiometer. Then a jumper from + 12 V dc will switch the 555 to a space and the space tone pot is set for 2295 Hz. During the first hour or so of operation after power on, some drift will be seen on the counter for both the mark and space frequencies. About 10 Hz over an hour's period was observed. Since both the mark and space tones drift about the same amount, this will present no problem *for amateur* demodulators since these small drifts are well within the demodulator's bandpass.

After setting the frequency of the mark and space tones, their amplitudes are set by a third pot to be about equal. An oscilloscope or a VTVM is needed for this adjustment. The tone output then is jumpered to the demodulator input, and the mark and space filters are adjusted. Three pots in each filter are adjusted for maximum deflection on the front-panel meter. Add a cover and sides, and the TU-170 is completed. The unit now is about 7.25" wide by 3.25" high by 7.25" deep. It is grey and black, and rather attractive. It easily blends into most stations.

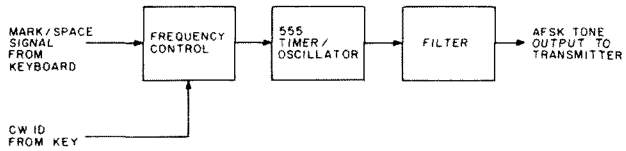

Fig. 3. Modulator detailed block diagram.

The next step is to hook up the TU-170 to the station transceiver and teletype. I use a Yaesu 227R here, on 2m FM. Yaesu has thoughtfully provided all of the necessary connections needed on an accessory connector on the rear panel of the 227R. These signals are: push-to-talk, microphone audio input, and speaker audio output. I leave my speaker connected while in the RTTY mode so that I can hear the tones and know that everything is OK.

You should use shielded cable for all connections between the TU-170 and your transceiver. Multi-conductor cable with a single outside shield is OK, but I used separate lengths of individually-shielded wire for each signal. Just use good techniques and you won't have any problems.

If your rig does not have an auxiliary connector with the proper signals available, then you can use the microphone input jack and earphone/speaker jack. If you do use the auxiliary connector, as I did, the TU-170 modulator will be in parallel with your transceiver microphone. When receiving, you then will hear a tone coming out of your microphone, since the TU-170 is always generating a tone whether it is in transmit or receive. The microphone in this case acts as a speaker. Also, *you* probably will not be able to transmit on FM voice when the tone is on, since it is strong enough to drown out the audio from the microphone. The simple solution is to turn the TU-170 ac power switch off whenever you are in the FM voice mode. An alternate solution is to add a switch to the TU-170 to disable the 555 oscillator. A number of other stations use computers on RTTY in our area. The TU-170 has TTL input and output lines to allow it to be connected easily to your favorite computer.

Once your hookup is complete, you are ready to start. I would suggest that you listen at first to get a feel for how conversations are held. Good operating practice is to wait after a station has signed to allow others to break in. When you feel ready, jump in with your call.

Well, there you have a description of my first experiences with RTTY. The Flesher TU-170 has now been in use here at WB6CRD for some time without any problems whatsoever. It Is a first-class unit for either the beginner or the old-timer, and can be used with computers. The world of RTTY has now been opened to me, and it is a fascinating world. I highly recommend it to you.

The TU-170 is available in kit form for $169.95. For more information, contact *Flesher Corporation, 507 Jackson, PO Box 976, Topeka KS 66601.* Reader Service number 484.

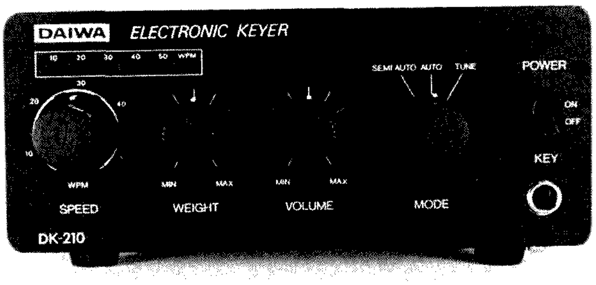
DAIWA DK-210

The gang at *73* knows I'm a CW freak and spend most of my time at the low end of the various bands, hanging out with others of like persuasion. For years, I've been using a time-honored but somewhat passé



The Daiwa DK-210 electronic keyer.

"TO" keyer...one of the tube-type keyers made by Hallicrafters as the HA-1...but still a real standard in many shacks, even today.

Like many of you, I suspect, I didn't even know that Daiwa made a keyer. Sure, we all know about their swr and power meters...the ones with the "crossed" pointer readout... and we know about their line of antenna tuners, but a *keyer*?

First impressions are important, and Daiwa doesn't let us down on this vital part of product marketing. The Daiwa DK-210 electronic keyer comes in the expected plastic-wrapped package with accessories separately wrapped and packed in the same carton. These include two RCA phono plugs, a power cord, and a power plug.

The DK-210 is dark grey in color and feels quite heavy... heavier than you'd expect for its size...a quality feeling. The crinkle finish is well done, and the front-panel markings stand out clearly against the dark finish color.

In this model, there are five small rectangular LEDs in the upper left-hand corner, surrounded by a white outline. Each LED is labeled with a number: 10, 20, 30, 40, and 50 (wpm); more about these later. The left-hand knob is labeled SPEED and obviously sets the speed of the dots and dashes generated by the keyer's electronics. A segmented circle around the knob is marked with the same numbers, corresponding to the LEDs...again an obvious (but welcome) feature.

A second knob is labeled WEIGHT and has a scale whose limits are marked MIN and MAX. This knob controls the dot-dash ratio and space; at MIN, the ratio is exactly three to one... that is, the length of time occupied by one dash is exactly equivalent to the time occupied by three dits. If you like to slur your keying and send code that has a different ratio, you have plenty of adjustment to play with. I would guess that beyond about the ten o'clock position of the pointer on the knob, you might succeed with a setting that nobody could decipher!

The DK-210 has a built-in speaker and tone generator so that you can monitor your own sending. The tone is pleasant and sounds something like the monitor of the transmitter itself. There is an external volume control, while the tone's pitch may be adjusted by a small screwdriver-slotted plastic shaft on the rear panel of the keyer. As it was received, I'd guess the tone was about 700 Hertz...just right for my ear, so I didn't bother changing the pitch. If you like stereo, you can use the transmitter's own keying monitor playing counterpoint to the built-in keyer monitor. I do that sometimes to relieve the monotony of a single tone.

A rotary switch allows you to select SEMI-AUTO, AUTO, and TUNE. In the SEMI-AUTO position, dots are generated automatically but dashes must be made manually, like the old-fashioned bug keyers. In the AUTO position, the key is a full electronic keyer with all automatic functions, including the desirable iambic-keying capability...something I've not yet taught myself to use. No matter—it works just fine with my old-fashioned type of thumb and forefinger input. (One of these days, though, I've got to learn to use iambic, or "squeeze," keying as it's called.)

The tune position is to allow you to turn your transmitter on in the way you used to do by holding the old pump handle in the down position...that is, to make a steady tune-up signal on the ~~band~~, er...ah, the dummy load. Finally, at the extreme right side of the front panel is the toggle switch that turns the power on and off, as indicated by an LED just above it. Below the toggle switch is a standard quarter-inch phone jack. Naturally, I had to change mine from the one I had on it back to the standard! Oh, yes, I almost forgot: It's labeled KEY and that's where you plug in your paddle.

On the back panel there's an accessory power-input jack for the usual 8-to-13.8-volt dc power-input plug...the style that you are used to seeing on tape recorders and other electronic devices that need that kind of power. More about *this* later, too!

Two RCA-type phono jacks are also on the rear panel. One is red and the other, black. The red one says DIRECT and the black one says GRID BLOCK. This means you can use the Daiwa 210 to key an old-fashioned cathode-keyed rig (limits are 300 V, 100 mA, max.) or one of the newer rigs in which the grid of a control tube, or a solid-state device, is keyed (limits are −100 V, 10 mA, max.).

Having an Icom IC-720A to key, I used the grid block outlet and managed to use one of the accessory phono plugs thoughtfully provided by Daiwa. Next, I looked for a source of power. Failing to locate an appropriate source of 12 volts dc with the proper plug right away, I decided to remove the top cover of the keyer (per instructions) to locate the battery holder...and install a 9-volt battery.

Whoopee! The keyer lighted up and a few dots and dashes caused the LEDs to glow...first the 10, then the 20, and finally the 30...sort of a progressive display running from left to right. The instructions suggest that if you run on battery power it would be a good idea to disable the LEDs to reduce power consumption. Likewise, it would be a good idea to forgo use of the keying monitor/speaker.

I quickly tuned in a station, gave him a call, and asked for a critical keying-quality report. The reply was a definite "Sounds great here, OM." I was in business!

All that evening I used my keyer, even forgetting the 300-mA current drain, until the battery started running low. Low battery power is evidenced by the keyer failing to keep up the set speed and the LEDs failing to light up. The "weight" is not affected, however.

Knowing that my time on remaining battery power was limited, I decided to hook up the small utility supply I had to provide all the power I would need for a weekend of CW. Easy, I figured...just do the normal thing...hook up the positive lead to the center pin, the negative lead to the shell, and *oops*! Immediately I suspected my supply, but that turned out okay. A closer look at the input jack on the Daiwa showed the reason (I needed a magnifying glass to read it). The center pin, friends, is negative while the sleeve is positive! After changing the leads on my supply, I got an immediate indication of all being normal and happy with the keyer.

I checked the LED indication of speed (in which several characters are integrated by the circuitry to read out an average speed) and the dial setting of speed, and they seemed to coincide very well. My normal conversational keying speed is around 30 or 35 wpm, and that's where I set the speed control; it also was what the LEDs indicated I was doing. I found that at higher speeds a slight slurring of dots and dashes is smoother sounding, and this was easily achieved by adjusting the "weight" control pot to about the 9 o'clock position. Just enough to make it pleasing to my ear.

The 6-inch-wide, 2.5-inch-high, and 6-inch-deep box hardly occupies any space at all on my operating desk. In fact, it's so neat-looking and so unobtrusive that I have given it a place of honor right next to my transceiver...which it complements beautifully. Altogether, I guess I've operated the little Daiwa 210 electronic keyer about 25 or 30 hours now, and it hasn't missed a beat.

Complaints: none, except at my own stupidity for not reading the nice little instruction brochure with its illustration of polarity on the power plug plainly shown! I have known for years that one ought to read the instructions first, but—like many of us—I figure it's so simple that reading instructions isn't necessary. Well, I learned.

I don't have much stray rf floating around the shack as all my antennas are current-fed, and the high-voltage points are far removed from the equipment. Nevertheless, if you end-feed an antenna and bring it into the shack to your tuner, you might have to use shielded keying leads between the output of the 210 and your transceiver. Rf has a funny way of producing not-so-funny results with solid-state devices.

Anything else? Just one thing: Daiwa also makes a nice version of this keyer without the LEDs, and it's called the model 200. Just in case you don't care for the speed-readout system, or don't feel it's necessary, or maybe want to save a few pennies, you might prefer the 200.

The DK-200 is priced at $82.50 and the DK-210 sells for $99.50. Daiwa keyers and instruments are distributed in the United States by *MCM Communications, 858 Congress Park Drive, Centerville OH 45459.* Reader Service number 480.

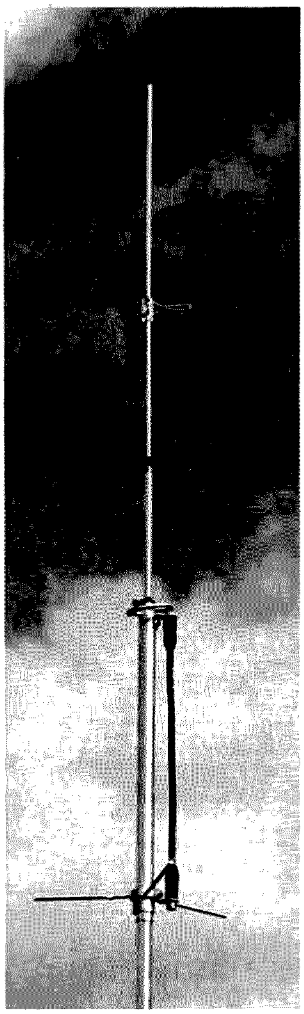
NEW PRODUCTS

BASE STATION ANTENNA

Ringo Ranger II is the newest addition to the Cushcraft line of Proline base station antennas. This improved model has 5.5 dB gain with an additional 5/8-wave section and decoupling radials for a low angle of radiation. All Ringo Ranger II antennas are broadband and easily field-tuned for quick installation. They are made from aluminum, with stainless steel hardware.

There are models covering the frequency range from 146-512 MHz. The Ringo Ranger II is priced at $49.95. For more information, contact *Cushcraft Corporation, PO Box 4680, Manchester NH 03108; (800)-258-3860.* Reader Service number 479.



Cushcraft's Ringo Ranger II base station antenna.

CALLSIGN DISPLAY

G & T Service Company offers a 3" x 8" callsign display. It is available with black, blue, red, green, or woodgrain background and white letters, or a white or yellow background with black letters. G & T also offers a clear Plexiglas™ holder. The callsign display sells for $6.00 plus shipping. For more information, contact *G & T Service Company, 3210 N. County Line Road, Farwell MI 48622.* Reader Service number 476.

ICOM IC-740 HF TRANSCEIVER

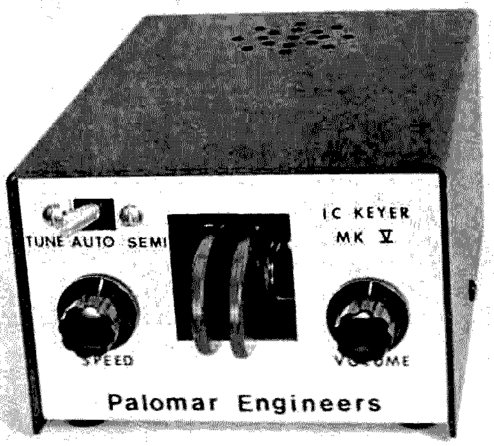
The Icom IC-740 is a versatile transceiver with front-panel or top controls that allow access to all operating functions. Adjustable receiver parameters include rf preamp, rf gain, noise blanker (width and level) i-f shift, passband tuning, crystal filter in/out, notch filter, agc (time constant and on/off), squelch, tone, and audio gain. Transmitter controls are mike gain, VOX, compressor, and power (10-100 W). The IC-740 includes capability for operating in the FM mode.

The frequency synthesis network includes dual vfo's with three tuning rates, split operation, and memory. Analog control of frequency with the incremental tuning on either TX, RX, or both. Full metering of receive-signal strength, transmit-relative rf output, compressor level, ALC and collector current, plus a built-in swr meter.

A large selection of options allows tailoring the IC-740 to your needs: a frequency marker, FM module, built-in electronic keyer, two 9-MHz i-f CW filters, three 455-kHz i-f CW filters, and optional internal power supply. The suggested base price for the IC-740 is $1099.

For more information, contact *Icom America, 2112 116th Ave. NE, Bellevue WA 98004.*

The Icom IC-740 transceiver.



Palomar Engineers' MK V electronic keyer.

PALOMAR ENGINEERS' ELECTRONIC KEYER

Palomar Engineers has announced the new IC keyer, the MK V. It features a 1-Ampere silver contact relay output that will key all ham rigs and most shipboard transmitters. It keys either polarity without change of jumpers.

The keyer features the fully-adjustable Ham-Key paddle and Curtis IC. It is available with either standard operation or type-B action. The keyer has a sidetone oscillator, speaker, volume and speed controls, mode switch, and an internal pitch control. It operates from a clip-on 9-volt battery for complete portability, or you can use a 9- or 12-volt dc power supply.

The MK V sells for $132.50 plus shipping/handling. For more information, contact *Palomar Engineers, 1924-F West Mission Road, Escondido CA 92025.*

AUTOCONNECT'S AUTOPATCH

AutoConnect introduces Private Patch. Since Private Patch does not employ the sampling technique, there are no repetitious squelch tails. In addition to simplex capability, AutoConnect's technique of audio and digital signal processing also permits operation through repeaters.

A five-digit user-programmable access code and long distance/operator-restrict switch protect your phone bill. A front-panel ringback switch permits incoming calls when desired.

Additional features are CW identification and a six-minute shut-down timer with reset code for additional talk time.

The Private Patch's introductory price is $489. For additional information, contact *AutoConnect, PO Box 4155, Torrance CA 90510.* Reader Service number 477.

THE GLOBAL SPECIALTIES SOLDERLESS BREADBOARD

Designed specifically for microprocessor applications, the new PB-105 solderless breadboard from Global Specialties Corporation contains five binding posts, 18 distribution buses, and six solderless breadboarding sockets. The 9.2" x 11.4" x .05" (234 x 290 x 1.3mm) "Superboard" offers 50 percent more breadboarding area (up to 48 14-pin ICs) than the next smaller size.

Conductive spring clips within the breadboard body securely grasp component leads and connecting wires. Parts plug in and pull out without damage. Vinyl feet are mounted to the underside of the backplate to prevent slipping or damage to the bench top.

Proto-Board assemblies are engineered for use in design, test fixturing, quality control, prototyping, evaluation inspection, and custom circuit applications. Suggested US resale price is $115.50.

For further information, contact *Global Specialties Corporation, 70 Fulton Terrace, New Haven CT 06509; (203)-624-3103.* Reader Service number 484.

MFJ ACTIVE RECEIVING ANTENNA

MFJ has introduced a new active outdoor receiving antenna with outdoor whip that gives reception of 50-kHz to 30-MHz signals. At lower frequencies, it is equivalent to an outside wire antenna hundreds of meters long. At high frequencies, it has high-gain amplifying action.

A high-dynamic range rf amplifier is mounted at the antenna for maximum signal-to-noise ratio. A 20-dB attenuator switch on the control unit prevents receiver overload.

The new antenna comes complete with a 50-foot coax cable with connector. It is available from MFJ Enterprises, Inc., for $129.95 plus shipping and handling.

For more information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 478.

CORRECTION

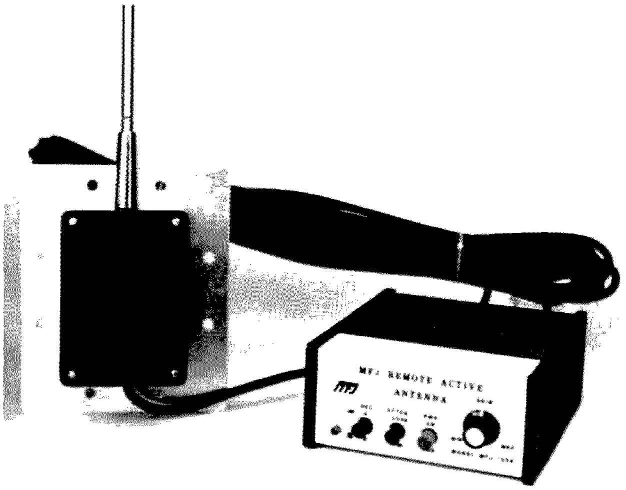
Please note that the TMAC Products weather station mentioned in our July issue (page 106) is powered by 115 volts (*not* 155 volts as stated).

THE DYNATRACER DT-1 CIRCUIT ANALYZER

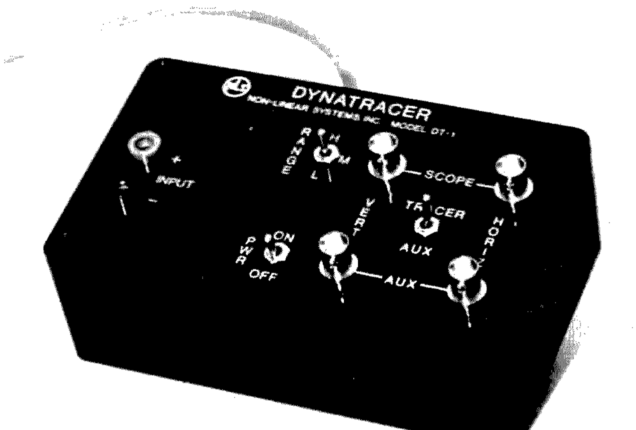
Non-Linear Systems, Inc., has added the DT-1 Component Signature Analyzer as a companion to its line of miniscopes. Designated the DT-1, the instrument has a capability as an in-circuit tester producing displays distinctive to the particular component or circuit being tested without the application of power to the circuit under test. DT-1 can be used with any oscilloscope equipped with an X-Y input.

The unit will display on the associated oscilloscope screen waveform pattern the condition of any component or group of components within a circuit. Accessories include a test-lead assembly, BNC-to-BNC cables for attachment to scope, and a unique component test adapter for testing radial-lead components without test leads.

The price for the DT-1 is $150. For more information, contact *Non-Linear Systems, Inc., PO Box N, Del Mar CA 92014.* Reader Service number 481.



The MFJ outdoor active receiving antenna.



The Dynatracer DT-1 circuit analyzer.

LETTERS

PRO CODE

I just wanted to get my two cents in on dropping the code as mentioned in Wayne's editorial. Like the column "Never Say Die," in my opinion, "the code never will." Code has always been a great part of ham radio and I hope it stays. Code is a language everyone can enjoy and communicate by. It took me quite some time to learn it, I grant you, but I stuck with it. If you want something bad enough, you can do it—and with great satisfaction.

Sounds like code came very easy for you—5 wpm in one hour. You must not have enjoyed something coming so easily, since now you feel code should be abolished. My spelling is terrible and I learn slowly. But I made my Extra and sure am proud of it. And if I can do it, most anyone can.

I'm sure glad Garth Evans is on our side of the fence. Like Garth said, "you have to dangle a carrot in front of the horse to get more privileges." Wayne, you say Bash is cheating, but are you sure you're not getting some kickback from Bash? Because with no code test, all you have to do is buy a Bash book, read a few hours, and you'll have your ham ticket. By the sounds of it, Wayne, you would like to see the ham bands turned into another 11 meters (chicken band). Well, that's my two cents. All in all, Wayne, you have a great magazine, but not all your opinions are great.

Ron Ostman KA0AYN
Eden Prairie MN

Ron, I admit that my opinions may not seem all that great if you ignore most of what I write and take little bits out of context and try to argue about them without mentioning the rest. Never have I ever suggested doing away with the code test and then leaving everything else the same. I guess you just read little parts of what I write and then wonder why I am not clear in my thoughts. You must really think I

am stupid if you think I want any of our ham bands to be like a CB channel. No, whenever I suggest canning the code, I also tie with it a much more serious technical exam, one which Bash will be unable to compromise. We have what is supposed to be a technical hobby, not a skill hobby, and the entry exam should reflect this.—Wayne.

NO CODE

I've read and reread your thoughts about code-free amateur licenses in the March issue of your mag, and hope someone out there listens to you. I've wanted to become a ham since I got into electronics in 1946 (remember the old jokes about the "drip pan for the grid leak?") but have simply *no* interest in learning Morse code. The technical side of ham radio and electronics in general is fascinating to me, and I spend much of my free time working up a new circuit I've seen somewhere or trying to keep up on technical reading (that could be a full-time job nowadays!). Of course, *73* occupies a few hours every month.

I designed high-fidelity amplifiers back in the '40s when nobody else knew what I was talking about and thought I was kind of nutty. I made the transition to solid-state with only mild trauma. I even went the CB route for a short while, but gave it up. They are, generally, foul-mouth rednecks with IQs in the low 80s or so. There are some exceptions, sure, but they are too rare. I have a lot of reading and research to do on TVRO now (great series by WA4CVP and WA4OSR you've been running lately), so I'll take out my frustrations on the microwaves. Keep up the good work.

Jim White
Sacramento CA

WELFARE ATTITUDE

Here I am again, reading the June *73* Letters column. Seems as though you continue to bash away at Bash, and your no-code license controversy goes on unabated.

Assume for the moment that you get your way. The most obvious question is, how do you propose making your theory test Bashproof?

As for the club idea, it has been my observation that most clubs, no matter how enthusiastic they start out, soon deteriorate into the usual 5% doers and 95% hangers on. It would seem that the result would be to put into the hands of a few elitists the power to decide who gets a license. A disinterested FCC bureaucrat hireling is probably best qualified to apply the rules equally to all applicants.

I think the basic problem lies not specifically with ham radio, but with our society in general. Only when the pride of personal accomplishment replaces the welfare attitude will Bash die and amateur radio grow—no matter what the entrance requirements.

Henry Testa KB6PM
San Diego CA

Henry, it isn't our society that is different. . . people have always been like that. People do things because they enjoy them and feel some sense of responsibility and accomplishment. The more we get people involved in amateur radio with responsibilities, the more enthusiasm I think we'll have. Amateurs who have been around for ten years can remember the real enthusiasm of the FM and repeater pioneers. Clubs formed all around the country. We had growth, enthusiasm, and excitement.—Wayne.

EMERGENCY SYSTEMS

I have been a reader of *73* since Wayne started it in Brooklyn NY, and have been an avid reader of the "Never Say Die" column. I must make a few comments on your June, 1982, issue.

You are advocating a national policy for emergency communications, which, by the way, I agree with with only one difference. I am afraid, Wayne, that our equipment is becoming so complex and sophisticated that very few hams have the capability and know-how to maintain/service same. In a real emergency, when the big national/military systems have gone up in atomic smoke, most of our present equipment will have gone the same way through the action of EMP (see AK0Q's article in the same issue). This guy knows something that few hams know.

I am retired now but have been involved in military communications planning for many years and have come across this subject many times. Much of the material is still in the Top Secret drawers. While the military can replace its black boxes because they have thousands in reserve and cost is no object, the poor ham is out of business when all our beautiful idiot lights are out. I suggest you give this some thought and, instead of advocating more sophisticated emergency equipment, let's think of survivability also. The only way to survive in my opinion is if hams can maintain their own equipment with minimum reliability on the manufacturer. Yes, I am thinking the unthinkable. Emergency equipment should be simple tube equipment, with at least one of each tube on the shelf in reserve. Above all, it should be maintainable.

Also, Wayne, let's face it: If the unthinkable ever happens, there will be no power and no gas for our gas-guzzling generators, so all of our emergency equipment should be battery-operated with, perhaps, a solar trickle charger. Some enterprising company might be induced by you to engineer a packaged transceiver/battery power system at reasonable cost and simple to maintain, remembering that it will have to be used and maintained when all has gone up in smoke.

I am sure that there are enough amateurs in every state to organize a truly compatible national emergency system. With your persuasive powers and *73 Magazine*, I am sure it can be done. I am truly interested in seeing such a system established, because I know that should the big cloud ever rise over New York, Washington DC, Chicago, etc., etc., all other systems will be down. There will be no power, no telephone, no commercial radio, and no transportation. Only a truly compatible, maintainable amateur system can survive.

Hope to hear more on this most important subject from you. Keep up the good work, Wayne. We need more like you.

Arnold Samuels KH6COY/7
Ocean Shores WA

Oh, I'm familiar with EMP, those electromagnetic pulses which accompany nuclear bombs. Getting information on the subject is difficult, but there have been some good articles in the more technical journals. It appears that unless we are hit close enough so we won't be around to worry about it, most of our solid-state ham gear will survive. . . particularly if it is not connected to an outside antenna. One of the nice things about solid-state equipment is its ability to run from twelve volts. Now, we may have a shortage of 120 V ac to run tube equipment, but it is going to be a long time before we run out of 12-V dc sources. You can even run transistor equipment from solar cells if you have to, but forget it with tubes. If you are worried about servicing the more complicated electronics, I suggest you turn the job over to a teenager, if you can find one. You've been spending too much time in the company of old-timers who are afraid to even try to fix transistor and IC circuits. Kids plunge right in and have a ball. . . and fix them. I can remember back to my early days in amateur radio when I built anything I wanted, fixed anything, and had a ball. —Wayne.

EX-DEALER CONFESSIONS

I was an amateur radio dealer. After many years of screwing around with the hobby, I found myself on the other side of the counter. The excitement was profound and when our first big order arrived, you can imagine the feeling. I mean, gosh, golly, see, I can open any one of those boxes and play to my heart's content. Anyone else would call it a mental disease but we call it being a "ham."

Imagine what it was like getting ready for opening day. All the expectations were there in full force. The doors went open, the phone was activated, and the ads were placed. And they came, saying, "Hey, this is great—we have a real ham store in town!"

For a few weeks it was, without a doubt, the peak of my long involvement with ham radio. What ham could ask for anything more? Then it started to happen. "Can't you fudge the tax for me?" "How about a better discount?" "Can't you ship the box to a friend in Pennsylvania and let me take the rig?" I actually shipped a cinder block in a Yaesu box to PA. Guess what happened. The damned block broke up, UPS

opened it and discovered the contents, and sent an inspector to investigate! Needless to say, I felt like a jerk and had a hard time explaining that one. I said it was just a joke. Dumb people do dumb things.

Then came the advent of CB. Not normal CB, but HF CB. All of a sudden, strange people were selling the same equipment I was—out of their garages and basements. I was one of those high-minded nincompoops who refused to sell to the HFers and required a ham license in order to buy a transmitter. Although I was able to purchase the equipment cheaper than these pseudo-dealers, I couldn't fudge the tax and I wouldn't "clip the brown wire" and cater to those illegal operators. You can see right there that I was never gonna make any money.

I would go to a hamfest in my own state and have to stand there like a jerk while an out-of-state dealer beat me out by not charging sales taxes! Complaining didn't do any good. Finally, after I went out of business, all hell broke loose at the Rochester hamfest. The state was wrong in their tactics but right in principle. Everyone in New York State lives with sales taxes and I don't see any of them pounding on the walls. It's ridiculous for hams to expect special consideration just because they're hams. If I was a hot-shot model-airplane enthusiast, I don't think I could expect to be exempt from sales taxes because my little airplane could fly typhoid serum across a flooded river in an emergency. We all do what we can.

When you operate a business, you're faced with all sorts of expenses. Aside from the normal bookwork, you have the state and federal government taking up a good percentage of your time. Then there's the overhead in keeping a walk-in showroom going. Insurance, upkeep, test equipment, tools—the list goes on and on.

Then there is "salesmanship." I'm a technical type and always tried to give the inexperienced the benefit of my knowledge. Unfortunately, most hams are already "experts" and no matter what you tell them, they know more than you do or their "buddy" does. The real culprit is the attitude of most amateurs. There was once a day when the amateur was accepted as a fairly knowledgeable radio type. He got discounts at the local radio store. Today, it's a different story. Amateur radio is a limited, special-interest hobby and is treated as a consumer item by the big importers.

The majority of rigs (at that time) were being sold to the HFers and not the hams. That was the era of the "Big Boom." This consumerism approach forced prices down and discounts were given because of the competition (via the 800 numbers). It was no longer feasible to keep an open showroom for people to come in, try the gear, make their decision on what to buy, and then call an 800 number and order to beat the tax. To make a long story short, the doors were closed.

I will be the first to agree that price is important. The only useful purpose of a local dealer is convenience—providing the opportunity to inspect and try the gear you're interested in and being there for service. But hams don't care about paying for service or convenience. After all, the manufacturer provides a warranty.

The only way any dealer can make it is to rely on mail-order sales or locate in a highly populated area. More significant is the realization that all this could end should the manufacturers and importers decide that they don't need dealers. Since they are providing the warranty anyway, they could install an 800 number and take over sales. Once the majority of the big outfits did this, they would have absolute control over pricing. As I stated, "ham radio is a limited, special-interest hobby" and there is no need for discounting. People don't build anymore, so where would you go to "beat the price?"

Once I discovered the requirements of a likeable and lovable dealer, I realized that I couldn't make money at it. I didn't have the personality for it. I couldn't stand cheapness, I couldn't stand listening to a guy who just went to Radio Shack and bought his coax and then came to me and bitched about the price of a couple of fittings. Yuk. I had guys who actually complained about paying a seven-cent sales tax on a dollar item. I've had people buy their radios elsewhere and come with a rig under their arm looking for warranty service. I've had people order parts for their gear and say, when I called them to let them know they had arrived, "Oh...yeah...I fixed it... don't need the parts anymore." A month later they call again: "Hey, can you fix my rig?" (Click.)

No, it wasn't all bad. I've had guys come in, pick out the most expensive units, never dicker on price, pay me in ones (from every pocket), and depart never to be seen again. That's when you crawl off in a corner muttering to yourself (or isolate yourself in the john with a copy of *MAD* magazine).

Yes, there are days when I miss it. I miss getting to play with all the "goodies" and being up-to-date with the industry. I miss the rumors of who is getting the favoritism and the best buys, and I especially miss getting the news about a new model, not from the maker or importer, but from the magazine ads (the model that's announced before Christmas—the one you order gobs of for the big rush in sales—only to receive maybe one and then get them all a month later when nobody is interested). I miss the double shipments, I miss getting all the accessories for an old model and not the new model. I miss all the trade-ins that blew up in my face. I miss hearing from the government that I didn't send in enough withholding. I miss getting ready for the next big hamfest. Yes, I miss it. The problem is that I couldn't make a living at it. In a sense, any present amateur radio dealer is giving his customers much more than they deserve, or he wouldn't be in business. I was not willing to give that much.

If you have a local dealer, support him even if you don't like him. You may pay a little more for the convenience but, in the long run, you'll find it's worth it. There is no way he can get rich and the only reason he is there is because he loves the hobby —one thing you both have in common. After he is gone, nobody will replace him. My business could have survived by concentrating on mail-order sales, but the profit level would not have matched money-market earnings. I think this is true with any dealer.

I just ordered a new Yaesu receiver. I did as most of you. I looked at the ads, found the "BESPRIZ," called the 800 number, used my charge card, and am now awaiting the brown UPS truck. It's so impersonal. There's no one I can go to locally, no one to bitch about the tax to, no one I can expound my knowledge to, no place I can run into fellow hams to BS with, no dealer I can get irritated with because he's had a bad day and is nasty. Hell, it's no fun at all. I think I'm becoming an "old-timer." I can build a radio out of a safety pin and a razor blade. Can you?

Jim Beckett WA2KTJ
Corning NY

CCD ANTENNAS

Cheers to the multitude of you (literally) around the globe who have phoned and written us about your success with the 5-dB-gain W4FD Controlled-Current Distribution multiband dipole (as described in our *73* articles in October '78 and July '81; also see the May '82 issue).

We are pleased that the United States Navy has appropriated monies to construct CCD antennas. (Here is an excellent opportunity for anyone wishing to manufacture, under very reasonable licensing conditions.)

Thanks most of all to this great magazine for bringing our story to you and for granting us permission to reprint the latest construction data. You may have a copy for a small, one-stamp SASE.

Gene Brizendine W4ATE

Huntsville AL 35803)
Harry Mills W4FD

AMATEUR HIGHWAYS

I wonder what you might think about getting the FCC to rescind the ruling giving extra privileges to the Advanced licensees in that these hams get the private use of the lower 25 kHz in the CW segments of the bands?

My idea on this is related to the use of the highways. Driving the roads and operating in the amateur spectrum are privileges granted by public agencies. Operators must show prudence and abide by the rules and regulations.

The highway privilege is expressed in several classes of licenses: Extra or Advanced for truckers, bus drivers, etc., and

General and beginners for the rest. The Advanced exam is given to help ensure good and safe driving skills. But these Extra class drivers share the highways right along with the General class and even the beginners.

In view of this, why should the ham bands be segregated? It seems to me to be a form of discrimination. The amateur bands are just that for amateurs of all classes. The Advanced or Extras may not think it, but they are still amateurs. Radio operating skill doesn't come with technical knowledge.

QRM keeps increasing with more contests and RTTY stations. By returning these 25 kHz to the majority of amateurs, our privileges would return to us more enjoyment.

C. M. Johnson W6EOT
Lakeside CA

C.M., your attempt at reasoning is weird, possibly brought on by having spent too much time in California. In the long run, I favor splitting up our bands the way we all agree they should be split up, with no FCC regulations on this at all. But if you think 25 kHz is going to give you more room to operate, you have another thing coming. That would be swallowed up so fast you would never know it had been there. No, if there is too much interference, we either have to move to bands which are not as crowded (and there are plenty of them) or else start working on communications modes which use our frequencies more efficiently. If you change to RTTY you will be able to communicate about five to fifty times as fast, thus having to be on the air much shorter periods, leaving some spectrum for others to talk. Just by using already known (but not used) techniques, we can communicate at 8,500 words per minute. Should we have a special express lane on your highway for 200 mph cars or do they have to drive at 55 mph along with the trucks and buses?—Wayne.

FIJI DX

As DX of some scarcity, although not really that rare, I must endorse Wayne's comments on pileups.

For DX stations, the first time at the bottom of a pileup is so terrifying that many never come back. On 20, for instance, many keep out of the American phone band for that reason.

My own technique, one which has enabled even the QRP stations to achieve a successful QSO, is somewhat similar to Wayne's. Once a pileup gets going, I go through the call areas in turn, starting with either area 5 or 7, and finish at 6 (6s here are really sounding like the proverbial Californian kilowatt). By asking for the callsign *once* only, and then answering the loudest heard, turnaround is pretty quick. And it gets rid of the tail-enders once and for all. Some doubling does occur, and there is always some QRM, but the beams at the other end seem to sort things out pretty well. And, once there is a successful QSO with just *one* QRP station, other stations in the queue are that much more patient—they know that their turn will surely come. Elbow jolts are far fewer.

A couple of comments for queue jumpers. They are right at the top of my hate parade—if others can wait, so can they. If they can't, *no* QSL.

Inexperienced amateurs wishing to QSL with rare DX should note the following:

Please make sure that your QSL card has all the information needed, and that it is right. I have had cards with the time wrong by hours, or which used local, not UTC, and cards on which the date has been wrong by up to a month (I wonder what they are using for log books—mine is written up as the call is made); there are even some cards here without the name and address of the operator!

For rarer DX, postage is a major expense. I know of some DX stations who will not reply unless some form of postage is included. One IRC will get a surface mail reply from most stations; if more IRCs are needed, "George Washington" may be both cheaper and worth more at the other end. If time is available, ask your DX station. He may prefer one or the other. Of course, many DX stations have a QSL manager. The same courtesies should also be extended to him.

As regards the magazine, when the format changed (with all the emphasis on techniques and a technology that will have little short-term relevance in the South Pacific), I was initially disappointed. However, upon reflection, I say, "go to it!" This is a hobby, with frontiers that the professionals simply do not have the resources to explore. Why, that is where *we* came from in the first place! And, as for my subscription to *73*, why, when I first decided to pay out a week's wages in 1966, when I first became a subscriber, my, it was a big decision. Now, I look upon it as an investment which is still returning great dividends after all this time. In fact, my most useful resource is nearly 16 years of articles on every topic in the hobbyist's field.

David Bell 3D2DB
Suva, Fiji

1966? That's the year I visited Suva and got on the air as VR2FD (Fuddy Duddy). I was using a borrowed Heath transceiver and I had a ball. Perhaps one of these days I'll be able to stop off at Fiji again and enjoy the Kava ceremonies, update my call to 3D2FD, and work a few more of the pileups.—Wayne.

FUN!

VHF-UHF COMMUNICATION

I've had a love affair with VHF-UHF radio that stretches back to my earliest days in this hobby. While any appropriately-licensed amateur with a few bucks can talk to the far corners of the Earth on HF, it takes skill—not just money—to work DX on 50 MHz and above.

Perhaps the reason for my fixation with the top frequencies has something to do with the way I entered ham radio. You see, unlike my fellow neophytes, I started my ham career with a Tech license. While I have nothing against either Novices or CW addicts, I've always felt more relief than accomplishment after passing a code test. Indeed, after I passed my Extra, I took all of my code cassettes and recorded music over them.

My proudest moment on VHF came on November 20, 1979. That was the day K7OFT and I (I was WB2IBE then) set the amateur distance record for a two-way A4 facsimile contact (New York City to Seattle, 2,430 miles, 50.250 MHz). Now that the FCC has opened A4 to the HF bands, I'm sure the record will soon be broken. Still, DX is child's play on HF. But experimenting on six meters and up—that's a different world.

ELEMENT 1—CROSSWORD PUZZLE
(Illustration 1)

Across

1) Increases receiver sensitivity
9) Interference type (abbr.)
10) A 6-meter activity (abbr.)
11) Not twice
12) Key maker
13) Circuit type (abbr.)
15) J-pole, for instance
16) Costa Rica prefix
17) Regret or French street
18) VHF-UHF combined antennas
20) Handle
21) Canadian rule-makers (abbr.)
22) The medium (abbr.)
23) Morse "standby"
24) Month after VHF QSO Party (abbr.)
25) A place to skip (abbr.)
27) Haiti prefix
28) Alaska prefix
30) HF rig to VHF rig

Down

1) Transmission of energy
2) Transmitter
3) Were you calling...
4) Night (abbr.)
5) After 2 down
6) Operating shot
7) Chip (abbr.)

8) Superhet and superreg
14) Old Novice prefix
19) Beam
21) Noise or connector
22) Sun
23) Hawaii prefix
26) League appointment (abbr.)
27) Top-type antenna
28) West coast city (abbr.)
29) Gate type

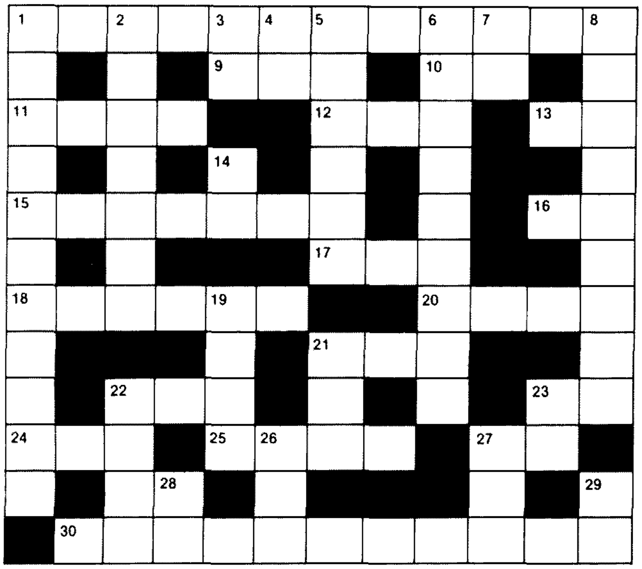

Illustration 1.

ELEMENT 2—FILL-IN

(Courtesy of Joe Reisert W1JR)

1) 6 meters: ______ to ______ MHz. The SSB calling frequency is ______ MHz.
2) 2 meters: ______ to ______ MHz. The SSB calling frequency is ______ MHz.
3) 1¼ meters: ______ to ______ MHz. The SSB/CW calling frequency is ______ MHz.
4) 70 centimeters: ______ to ______ MHz. The SSB/CW calling frequency is ______ MHz.
5) 23 centimeters: ______ to ______ MHz.
6) 13 centimeters: ______ to ______ MHz.
7) The two exclusive VHF CW bands are ______ to ______ MHz and ______ to ______ MHz.
8) The highest FCC frequency assignment is ______.
9) The first US station to work Europe on 6 meters was ______.
10) ______ popularized 144 MHz with his low-noise 417 tube converter.
11) ______, ______, ______, ______, ______, all have their calls on 432 yagis.
12) An early pioneer of EME from the W1 call area was ______.
13) The first recipients of 144- and 432-MHz WAS awards: ______, ______.
14) Name the ARRL sections in the W1 call area ______, ______, ______, ______, ______, ______, ______.
15) Name the ARRL sections in the W2 call area ______, ______, ______, ______, ______.
16) The call ______ set the all-time June multi-op contest record.
17) The lowest frequency two-way EME QSO was on ______ MHz and the highest was on ______ MHz.
18) The highest frequency where meteor-scatter QSOs have occurred is ______ MHz.
19) What mode of propagation is possible on 220 MHz, but is still unattained? ______.
20) Typical meteor-scatter QSOs rarely occur beyond ______ miles.
21) 10,000-mile-DX QSOs are possible on EME. True or false? ______.
22) Statistically speaking, the most popular frequency band and mode for VHF communication is: ______, ______.

ELEMENT 3—SCRAMBLED WORDS

Unscramble these terms relating to VHF-UHF communication:

VEAWGIDEU	LIRNDEAH	EVAWCRIMO
ISHD	PRETREEA	TTREACS
EREHPSOPOTR	ETASLTILE	KLIN
ECRNORTVE		

ELEMENT 4—MULTIPLE CHOICE

1) In which month of the year does the Leonids meteor shower occur?
   1) November
   2) July
   3) August
   4) March
2) If you put all of the VHF bands together (2 through 1¼ meters), how many total Hertz would you have?
   1) 60 MHz
   2) 60 kHz
   3) 16 MHz
   4) 13 MHz
3) In which year did we lose the 5-meter band?
   1) 1928
   2) 1941
   3) 1968
   4) Amateurs never had a 5-meter band.
4) In which year did the first US-Great Britain 6-meter QSO take place?
   1) 1934
   2) 1946
   3) 1969
   4) It's never been done.
5) Which of the following devices can be used to measure VHF frequencies?
   1) Lecher wires
   2) Grid drip-pan meter
   3) VTVM
   4) Frequency multiplier

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—50, 54, 50.110
2—144, 148, 144.2
3—220, 225, 220.1
4—420, 450, 432.1
5—1215, 1300
6—2300, 2450
7—50, 50.1, 144, 144.1
8—300 GHz and up
9—W1HDQ
10—W2AZL
11—W1HDQ, K2RIW, W0EYE, F9FT, N6NB
12—W1FZJ
13—K0MQS, W0YZS
14—NH, ME, VT, RI, CT, EMA, WMA
15—WNY, ENY, NYC/LI, NNJ, SNJ
16—W1FC
17—50, 2304
18—432
19—Es or sporadic E
20—1500
21—True
22—2 meters, FM

Element 3:
(Reading from left to right) WAVEGUIDE, HARDLINE, MICROWAVE, DISH, REPEATER, SCATTER, TROPOSPHERE, SATELLITE, LINK, CONVERTER.

Element 4:

1—1 I can't figure out why they would name a meteor shower after a Soviet president.

2—4 A lot of real estate. So why is everybody on 2 meters?

3—2 After the war we moved to 6 meters. Some stupid thing called "television" forced the change.

4—4 No 6-meter privileges in the UK.

5—1 There may still be some old-timers using these things instead of frequency counters. Check an old theory book for an explanation of how these devices work.

SCORING

Element 1:
Twenty-five points for the completed puzzle, or one-half point for each question correctly answered.

Element 2:
One-half point for each blank filled.

Element 3:
Two and one-half points for each word unscrambled.

Element 4:
Five points for each correct answer.

How did you do?

1-20 points—Like 220 at 3 am.
21-40 points—Misdirected beam.
41-60 points—Smart as a QSO on a calling frequency.
61-80 points—Very high IQ.
81-100+ points—Ultra high IQ.

P	R	E	A	M	P	L	I	F	I	E	R

FUN! MAILBOX

I just received my May issue of *73* and I'm pleased that so many were able to solve the DX puzzle printed in the January issue. On the other hand, I'm sorry, John, about the indignant comments you received. Obviously, the puzzle was submitted as a brain teaser and to have *FUN!*

The *really* sad part is that I have to inform you and the contestants that solution 1 is correct whereas the other two are not!

There are three pertinent time elements in the clues, namely, (1) previously worked, (2) now working, and (3) will work next.

Clue E states, "Jack, who previously worked Taiwan, will not next work Hong Kong." In effect, this clue says that Jack had just worked Taiwan but it doesn't tell who he is working now—only that he will not be working Hong Kong next. From this clue a partial sequence develops, namely, Taiwan to ???? to Hong Kong. Both solutions 2 and 3 show a sequence of Taiwan to Mongolia to Hong Kong, which is invalid. Hence solutions 2 and 3 are incorrect.

To be fair, however, I can now see that clue E might have been clearer if it had stated "...who had just previously worked Taiwan..."

Thanks for running the puzzle, John, and if any of the contestants want a copy of my solution, I'll be pleased to send it to them. An SASE would be appreciated.

Bob Young W1MXI
Belmont MA

Will we never find an end to the January DX puzzle? Here I am, getting my woolies ready for another winter, and we have yet another interpretation on that brain-twister. Personally, I think it's all a matter of semantics, and hope readers will take up Bob's offer of corresponding directly with him. As for me, I'm through with this one.—JE.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

new developments to keep us busy trying to keep up for months to come.

Being not completely unknown in the industry, I was taken behind the scenes to see some exciting new products not being shown at the show. As the publisher of four magazines in the micro field, I guess I get a bit too convinced of my visibility and am thus brought down to earth when a new firm gets into the field and I run into a group of people who have never heard of me or my magazines.

I went through this shock recently with the debuts of four DEC computers, two Wang systems, the Sony computer, and the Victor computer. More and more computers are being brought to the market by firms with virtually no knowledge of the microcomputer market. This seems like a recipe for disaster, but perhaps these firms will adapt and succeed.

The proliferation of low-cost computers is exciting. With the price of the Radio Shack Color Computer being dropped to around $300, the prices on the VIC-20 going to around $239, the Sinclair coming out via Timex at $100 (with discounts probably to around $88), the new Panasonic JR-200 at $300, the Commodore Max at around $150, and so on, there is going to be a lot of computing power available in the under $300 range. This means that there are going to be opportunities for programs, accessories, expansions, and so forth for these systems. Look for new businesses to start and soon be raking in millions. We are going to see a lot of new millionaires in the next few years.

After four hectic days of shows and four Eastern trips, it was time for a short vacation, so Sherry and I took Eastern to San Antonio for a visit with her mother in Seguin, Texas. Her father was away on a visit to my folks up in northern New Hampshire, so we missed him. We got a good night's sleep, had one of the fantastic meals Alma makes, and were on our way to the airport again. This time we went to Atlanta and then on to Ft. Lauderdale for the computer show there.

The show, held at Brower College, had not been as well publicized as one might wish, so the attendance was small. With all due respect, *Infoworld*, while a fine newspaper, is not the best bet for reaching hobbyists and people interested in computer shows. I think my talk cleaned out the exhibit hall completely, with 82 to hear me. Sherry and I

grabbed a nice lunch at the 94th Aero Squadron restaurant before the show. We enjoy that place, though our visits to Ft. Lauderdale are not all that frequent.

The talk over, we rushed back to the airport via Swenson's Ice Cream Parlor and a banana split. This time Eastern took us to Atlanta, but instead of the lounge we headed for town and the Marriott for the Atlanta Hamfestival.

The hamfest didn't seem to draw as large crowds as in many past years. I don't know if this is a reflection on the lack of growth of amateur radio, the economy, or the lack of anything really new and exciting to bring 'em in. Only about half of the exhibit booths had been sold, so most of the industry people weren't there. . . and the computer exhibits had almost completely disappeared. A couple years ago it looked as if the computer exhibits might push out the ham exhibits.

This lack of computer coverage may be a reflection of the turn in interest of the show promoters. A few years ago I worked with them to put on the heat to bring in computer exhibits and computer interested readers. I didn't hear much from them this year, so I didn't do much. Something big is needed to bring this great hamfest back to life.

I'm not fussing with the committee, for they were as cooperative as they could be for me. At the last minute, when I found I had a day between my Ft. Lauderdale talk and a trip to Colombia, Chaz arranged a spot for me to give a talk. . . at 2:00 pm Saturday, the best time. They did everything possible to make my short visit comfortable and fun.

For some reason, Sunday is the big day at Atlanta. Most hamfests only pull about 50% as much traffic on Sunday as Saturday, but Atlanta has historically pulled more on Sunday. They did again. Some of the exhibitors who had been grumbling about the sparse attendance on Saturday perked up as sales boomed on Sunday. Well perhaps "boomed" is an exaggeration. Nobody was buying much in the way of expensive equipment. . . and the flea market was very depressing.

The hotel got on my recommended list with their luncheon. They had a do-it-yourself dessert buffet for $1.95. I think this is the first time I ever beat a restaurant on a buffet. I really did a job on that buffet, starting out with apple cobbler smothered with soft serve ice cream, then going on to sundaes with cherries, strawberries, chocolate, and pineapple. I was not able to get to the baklava, the cream puffs, the chocolate eclairs, and so on. Hmmm, if we can allow a little more time between planes in Atlanta, I wonder if we might. . . ?

Saturday night in Atlanta has turned into a ritual. Chuck Martin of Tufts was exhibiting, so his crew joined us on a trip out to Aunt Fanny's Cabin where we did the best we could with fried chicken, Smithfield ham, and all the fixings. Chuck, who had driven down, went back via the Knoxville World's Fair.

On Sunday morning, Sherry and I went back to the airport and Eastern, with a stop off in Miami on the way to Baranquilia. It's not as long a trip as I thought.

Once ensconsed in the Hilton in Cartagena, I began to wonder how I might get in touch with some of the local amateurs. I'd brought a page of the Callbook with me, so I had the addresses of quite a few hams in Cartagena (Car-ta-hey-na). . . but which of them spoke English? Sherry, who knows a dozen or two words of Spanish, tried calling a few of the hams, but never managed to get beyond their housemaids. Then she got the hotel operator to make the calls for us and we were soon in touch with HK1EDM and HK1FA, Victor, the president of the local radio club.

Armando Castillo HK1EDM, a local plastic surgeon, his daughter, with Victor Yacaman HK1FA and his wife picked us up for dinner on Monday. They took the time to drive us around the old walled city and fill us in on the fascinating history of the town. It seems that Cartegena was repeatedly attacked by pirates, often being captured. Some of the pirates were a bit more than we've seen in our movies, arriving with nearly 200 ships and 23,000 troops.

We visited the radio club, where I signed in the log. They have their own club premises, complete with a service bench for repairing ham gear.

While I didn't send ahead for a license since I would be there for only two days, I did have along a Kenwood HT, so I checked out the local repeaters. I had no trouble kerchunking five different repeaters from the hotel on 146.61, 64, 94, 147.06, and 147.24. I heard at least three more, but was unable to kerchunk them. Simplex was going strong on 145.05, 24, 85. You can bet that the next time I manage a day or two in Colombia at the end of a business trip, I'll have a license awaiting me and be busy talking on the repeaters. If I can get away for a couple more days I'll include a side trip to San Andres for some skin diving.

The trip back to Baranquilla was similar to the one down, complete with the singing children and small-town food vendors. The bus was smaller and hotter. Once at the airport, everything settled into routine and in a few hours we were back in Peterborough, New Hampshire, laughing over the problems and the fun of the visit.

The amateurs in Colombia, like amateurs everywhere, are wonderful people. I've never been seriously disappointed in my travels. Of course it helps when I am able to meet hams like Rudolf, who have been reading my editorials and already know me pretty well.

Eastern managed to get most of the Braniff routes to South America, so they've removed Colombia from their special around-the-airline fare. They may be working on a new fare system which will include more of South America. In the past I've found that I could, by putting up with the Atlanta stops, get to a couple of shows cheaper than to just one. . . and then be able to include a stop or two in the Caribbean as a bonus. Sherry and I managed St. Maarten, Martinique, and other such stops this way in the past. It's worth looking into. Eastern keeps inching up the cost of their around-the-system excursion fare, so check it out the next time you have to make a trip somewhere and see if you can't throw in a side trip to Antigua at no extra cost. I've only visited two South American countries so far, so I'm watching for something special from Eastern which could get me to a few more without a lot of cost. NSD stands for Never Spend a Dollar, which is consistent with my Yankee upbringing.

SUCCESS

A depressing bit of news was in a recent report in the *Wall Street Journal*. Unless they rewrote the study, something I have personally known them to do...so I don't give them a lot of creditability, this showed that a high percentage of the teenagers they polled had little interest in success. All they wanted out of life was to have a home, a job, and a family.

I suppose, considering the cost of homes these days, that might seem like an outsized expectation, but I find that I am angry with the schools which are teaching the kids these meager values. Remember, if you will, that many of the people we employ to teach our children...the people who are giving them much of their values...are failures as far as coping with our economic system is concerned. It is a pity that parents have so little real choice in schools...and make this even worse by having virtually no communication with their kids. At home, the television set is on and other studies have shown that the parents will fight almost to the death to keep it on, day and night.

Without much in the way of real communication with the parents, children have to learn from television and school... neither of which is inspiring. Are there any TV shows which show successful people accomplishing things? In most of the shows I've seen, the heads of large corporations are busy ordering people killed, stealing formulas, and other skullduggery.

Our school system is set up so as to virtually guarantee failure as far as making any real money is concerned. Pity, for the more money you make the more ability you have to help move the world ahead. The less you make, the less say you have in what is going on. Yet we have our schools set up so as to provide employees for large businesses (no one has ever gotten rich as an executive in a large business...according to John Wareham in his *Secrets of a Corporate Headhunter*...a superb, if probably disturbing book). If one continues on through the educational process, one finds the goal is teaching, another proven way to stay impoverished.

With little, if any, input to the kid from the parents, I suppose it is no wonder that our kids have no enthusiasm for success. This is something which happens in early schooling, so by the time a kid might get a chance to listen to me it is too late.

This is frustrating, in a way. Here we are in the middle of the computer revolution, with opportunities on every side for youngsters to become incredibly successful, yet most of them don't want to and won't make even a slight effort to try. We've already seen more new millionaires as a result of the microcomputer in the last two or three years than we've had in any similar period in history...and this is only the beginning. We are about to enter a computer/communications explosion which will force millions on many more entrepreneurs. It's all there if you want it.

Being, for some reason, an entrepreneur, I see these opportunities opening up on every side. And I see a lack of people with the background it takes to succeed. I'm held back from getting into many more projects by lack of money for growth...and a lack of able people to follow up on the work that has to be done. Oh, we're growing at about 40% or so a year, but the opportunities are out there for ten times that in growth...if the venture capital and management were available.

Well, enough grousing about my frustrations. If I can organize a pilot model college to provide an entrepreneurial education I think our country would be able to grow faster and cope more successfully with the Japanese. I don't think we will ever do it with big corporations and the type of people they generate.

EMERGENCIES

Speaking of frustrations, I'm still looking for articles on advanced emergency communications systems which amateur radio could pioneer. Not only does amateur radio need the boost such new systems would provide, but our country needs the safety which such systems could provide. Right now, if the bombs should drop, we'd be in one hell of a fix. A recent disaster novel, *Satan's Hammer*, spells out many of the problems we would face should a major disaster occur. Unfortunately, the authors of the book were unfamiliar with amateur radio, a service which will obviously be of key importance in any calamity.

It is a crime that amateur radio has managed to keep the traffic nets using CW for the last 30 years. When John Williams W2BFD and others showed the simplicity and effectiveness of RTTY back in 1948, it was time to make the change from Morse code to RTTY at 60 or 100 words per minute. Now, with a computer within the reach of anyone (Sinclair, $100), what on Earth are we thinking of trying to send emergency messages with a hand key at ten or twenty words per minute? What do I have to do to get some action, start an Amateur Radioteletype Repeater League to bring us into the last half of the century? Yes, I know that virtually to a man you are about my age...which is sixty this year...and that you are tired and don't want to try anything new. Well, dammit, stock up on All-Bran and prunes and let's get this old ark a moverin. I want to see some sign of experimentation, even if we have to develop the action in the geriatric set.

In case you have managed to avoid the news programs on television, more and more countries are going atomic. This means that one of these days a little war, such as our recent conflicts in Lebanon, the Falklands, and so on, could escalate into that projected loss of 140 million Americans. Yep, there goes old gloom and doom Wayne again...and I admit it this time. Sure, I agree with you that such a thing is so terrible that it is absolutely impossible. But I don't believe that any more than you do.

We both know that it is highly unlikely...but the possibility has to be reckoned with. Now if amateur radio could come into the 80s and get some emergency relay systems working... automatic relays...with high speed digital communications...we just might have something left should all hell break loose. If we are going to depend on CB for post-atomic communications, we are not going to have a workable government.

You probably don't have the guts to bring this up at a club meeting and get things started. I don't blame you. No, it's better to get mad at me for bringing it up and do be sure the next time you see me to assure me that you don't always agree with everything I write.

IONIZED!

The article on negative ions in the July *73* (page 52) left out a very important piece of information that you really should have before you start pouring ions around your house. There's a little side effect of these damned ion generators which they don't tell you about...one which can cost you a bundle.

There has been a mystique about negative ions for years. All sorts of claims have been made for them at various times...such as that they help you to think better, to feel better, to heal faster, and so on. Articles have pointed to positive ions as bringing on depression and even suicides.

With the government taking a dim view of sales literature promising cures for things where proof is lacking, the brochures for negative ion generators are a marvel of hyperbole without anything really being promised. These ads do not promote confidence in the product.

Yet it seems as if there must be *something* there. I can't help but notice that virtually all of my really brilliant ideas come while I am taking a shower. If I sit in a tub of water nothing much happens. I probably should have a shower attached to my office and pop in and out a dozen times a day. I've read that this is not an unusual occurrence and that it is thought to be the knocking off of positive ions by the shower water which is responsible. This is supposed to build up the negative ions, allowing the brain to function better.

Now, as any of my great army of detractors will vouch, anything which will help me think better should be pursued. So it was only a matter of time until I got sucked in and bought one of those negative ion generators for my office. It was a little one...one of those small black ball types I'm sure you've seen advertised. Mail-order item. Well, it arrived and I plugged it in and put it above my desk and awaited flashes of brilliance. Nothing happened.

These gadgets are being sold as smoke-clearing devices. I've seen demonstrations of how they precipitate smoke out of the air almost instantly. Well, that's great for some offices, but I don't smoke. I don't hire anyone who smokes. I don't let anyone smoke in the building, much less my office, so *that* function of the generator isn't very helpful... but it does tie in with the disastrous side effect.

A couple months ago I got an ad in the mail for a more powerful ion generator. Hmmm, perhaps that was the trouble, not enough ions. So I sent for this powerhouse ion generator and waited with hopes of being able to keep brilliant thoughts perking day and night.

The contraption arrived. It wasn't a lot larger than the black bomb sitting on the bookshelf over my head. *This* is a powerhouse generator? Oh, well, I put it on the shelf and plugged it in and waited for genius to strike. And *I* waited.

There must be something wrong with the idea. Here I was awash in negative ions and I felt tired and needed to lie down for a nap. Phooey. So I reached down to unplug the new generator and got zapped. That sucker had zillions of volts jumping out of the power plug... I couldn't get near it. Did I have the plug in backwards? I got some insulated foam and changed the plug around. Nope, still the same...hot. That's dangerous! There must be 100,000 volts jumping around that wall socket. You know, it's mighty difficult to pull a power plug when you know it is going to give you a dandy shock, even with insulation. I sent the gadget back to the mail-order house and got a refund.

Okay, now the real kicker. After a year of sitting under my black bomb awaiting benefits, I moved some of the boxes of magazines which were on the shelf to another room. For a good ten feet around the generator, every book or box on the shelf had an outline around it printed permanently on the wall. A picture on the wall six feet from the generator was nicely outlined in black. It was as if I had sprayed the wall with dark grey. That damned generator had attracted the dust in the air to the walls of the room...and the books, boxes, pictures, and so on. I got a hundred years worth of dust coating my walls in about one year! The office walls are a disaster. Even the ceiling at that end of the room is a much darker grey. The whole *room* will have to be painted.

I thought you might like to know before you get too enthused over the ion generator in the July issue.

HAM PUBLICATIONS

The virtual disappearance of *Ham Radio* magazine from hamfests and conventions has reinforced rumors that publisher Tenney would like to retire. There was some serious talk of that a few months ago, but apparently the chap interested in taking it over thought better of the idea after looking into the economics.

Tenney has been talking about retirement and his recent folding of *Ham Horizons* and getting rid of *Ham Radio Report* would indicate that he is winding down his publishing business. With the loss of editor Fisk, *HR* seems to have no one on the staff qualified to select and edit the more technical articles.

Since magazine publishers do have to take care of their subscribers when they fold their magazines, the usual move is to turn to a similar publication and arrange for them to fulfill the obligation. This is an expensive matter, but hopes of subsequent renewals and thus an eventual recouping of the investment often prevail.

With *HR* reaching the lowest point in advertising in ten years this spring, the losses must be considerable. However, should *HR* fold, you may be sure that ham high-tech articles will not disappear. We're preparing to open a section in *73* on this so that we can provide serious engineering builders the projects they like. We *do* have good technical brains on tap.

The way we keep score in the publishing business is by counting pages of advertising. For instance, to put things into perspective, in May, *73* had 93 pages of ads, *QST* had 91 pages, *CQ* had 58 pages, and *HR* had 37 pages. That about tells the story. With the break-even point for most magazines being at around 45% advertising these days, when one is only running about 37%, like *HR*, the chances are that money is being lost and something is going to have to change. They've been under 45% for a year, so it's probable that the losses have been mounting. Of course if circulation is kept small, it *is* possible to get by with fewer ads, so that could be their stratagem.

The main problem in the whole ham field is one of lack of growth. This has kept the sale of ham gear down and that, in turn, has limited funds for advertising. Advertisers tend to cut back and advertise only where they know they are getting the most sales, which puts the pinch on specialty publications such as *HR*. Tests often show that advertisers are able to do about the same in sales with or without ads in anything but *73* and *QST*. When sales are brisk and profits large, firms can afford to run ads in smaller magazines as a way of helping them. But when the bottom line starts turning red, these extravagances are reconsidered.

To perhaps put things into a better perspective, let's look at how advertising is going to *73*, *QST*, and *HR* for the first six months of 1982 vs. the same period in 1981.

Pages of ads

	1981	1982
73	426	534
QST	571	556
HR	301	212

Thus, in comparable periods, we see *73* advertising up over 25%, *QST* down about 2½%, and *HR* down 30%! Obviously something is happening.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

EUROPEAN DX CONTEST—PHONE

Starts: 0000 GMT September 11
Ends: 2400 GMT September 12

Sponsored by the Deutscher Amateur Radio Club (DARC). Only 36 hours of operation out of the 48-hour period are permitted for single-operator stations. The 12 hours of non-operation may be taken in one but not more than three periods at any time during the contest. Operating classes include: single operator, allband and multi-operator, single transmitter. Multi-operator, single-transmitter stations are allowed to change band only one time within a 15-minute period, except for making a new multiplier. Use all amateur bands from 3.5 through 28 MHz. A contest QSO can be established only between a non-European and a European station. Each station can be worked only once per band.

EXCHANGE:

Exchange the usual five-digit number consisting of RS and progressive QSO number starting with 001.

SCORING:

Each QSO counts 1 point. Each QTC (given or received) counts 1 point. The multiplier for non-European stations is determined by the number of European countries worked on each band. Europeans will use the last ARRL countries list. In addition, each call area in the following countries will be considered a multiplier: JA, PY, VE, VO, VK, W/K, ZL, ZS, and UA9/UA0. The multiplier on 3.5 MHz may be multiplied by 4, on 7 MHz by 3, and on 14 through 28 MHz by 2. The final score is the total QSO points plus QTC points multiplied by the sum total of multipliers.

QTC TRAFFIC:

Additional point credit can be realized by making use of the QTC traffic feature. A QTC is a report of a confirmed QSO that has taken place earlier in the contest and later sent back to a European station. It can be sent only from a non-European station to a European station, the general idea being that after a number of European stations have been worked, a list of these stations can be reported back during a QSO with another station. An additional 1-point credit can be claimed for each station reported.

CALENDAR

Sep 11-12	ARRL VHF QSO Party
Sep 11-12	European DX Contest—Phone
Sep 11-12	Cray Valley RS SWL Contest
Sep 18-19	New Mexico QSO Party
Sep 18-19	CAN-AM Contest—Phone
Sep 18-19	College Scrimmage
Sep 18-20	Washington State QSO Party
Sep 25-26	Maine QSO Party
Sep 25-26	CAN-AM Contest—CW
Sep 25-27	Massachusetts QSO Party
Oct 2-3	California QSO Party
Oct 16-17	ARCI QRP CW QSO Party
Oct 16-17	Pennsylvania QSO Party
Oct 16-17	BSA Jamboree-On-The-Air
Oct 23-24	Maryland-District of Columbia QSO Party
Nov 6-7	ARRL Sweepstakes—CW
Nov 13-14	European DX Contest—RTTY
Nov 20-21	ARRL Sweepstakes—Phone
Dec 4-5	ARRL 160-Meter Contest
Dec 11-12	ARRL 10-Meter Contest
Dec 19	CARF Canada Contest
Jan 8	*73 Magazine* 40-Meter World SSB Championship
Jan 9	*73 Magazine* 80-Meter World SSB Championship
Jan 15-16	*73 Magazine* 160-Meter World SSB Championship

A QTC contains the time, call, and QSO number of the station being reported, i.e., 1300/DA1AA/134. This means that at 1300 GMT you worked DA1AA and received number 134. A QSO can be reported only once and not back to the originating station. Only a maximum of 10 QTCs to a station are permitted. You may work the same station several times to complete this quota but only the original contact has QSO point value. Keep a uniform list of QTCs sent. QTC 3/7 indicates that this is the 3rd series of QTCs sent and that 7 QSOs are reported. Europeans may keep the list of the received QTCs on a separate sheet if they clearly indicate the station who sent the QTCs.

AWARDS:

Certificates to the highest scorer in the each classification in each country, reasonable score provided. Continental leaders will be honored with plaques. Certificates will also be given to stations with at least half the score of the continental leader or with at least 250,000 points. The minimum requirement for a certificate or a trophy is 100 QSOs or 10,000 points.

ENTRIES:

Violation of the rules, unsportsmanlike conduct, or taking credit for excessive duplicate contacts will be deemed sufficient cause for disqualification. The decisions of the Contest Committee are final. It is suggested that the log sheets of the DARC or equivalent be used. Send a large SASE to get the wanted number of logs and summary sheets (40 QSOs or QTCs per sheet). SWLs apply the rules accordingly. Entries should be sent no later than October 15th to: DARC DX Awards, PO Box 1328, D-895 Kaufbeuren, Germany.

EUROPEAN COUNTRY LIST:

C31, CT1, CT2, DL, DM, EA, EA6, EI, F, FC, G, GC Guer, GC Jer, GD, GI, GM, GM Shetland, GW, HA, HB9, HB0, HV, I, IS, IT, JW Bear, JW, JX, LA, LX, LZ, M1, OE, OH, OH0, OJ0, OK, ON, OY, OZ, PA, SM, S, SV, SV Crete, SV Rhodes, SV Athos, TA1, UA1346, UA2, UB5, UC2, UN1, UO5, UP2, UQ2, UR2, UA Franz Josef Land, YO, YU, ZA, AB2, 3A, 4U1, and 9H1.

BIARC BULLETIN

NEWSLETTER OF THE MONTH

This month's newsletter winner, the *BIARC Bulletin*, is chock-full of useful information. Published by the Big Island Amateur Radio Club, Hilo HI, the newsletter has an activity calendar that lists local, national, and international ham radio events, a directory of nets and bulletins, and even reminders for club members whose licenses are about to expire. The *BIARC Bulletin* also offers a special Hawaiian flavor, making it interesting to read even if you are not a member. Great job, BIARC, and great job, Editor Dean Manley KH6B!

CRAY VALLEY RS SWL CONTEST

Starts: 1800 GMT September 11
Ends: 1800 GMT September 12

Up to 18 hours of logging may be done during the contest period with a rest period clearly shown. Multi-operator stations may log during the entire contest. The contest is open to anyone in the world, and there will be two sections, phone and CW, each with two categories: single operator and multi-operator. The second category is open to two or more listeners or to clubs and more than one receiver can be used. The 1.8-, 3.5-, 7-, 14-, 21-, and 28-MHz bands may all be used.

Scores should be compiled as follows: one point for each station heard multiplied by the number of different countries heard on each band. A list of countries heard must be furnished and a separate log must be submitted for each band. Illegible logs will not be accepted. The call areas of the USA, Canada, and Australia will each count as a separate country. All other countries will be determined by the official RSGB Countries List. No CQ or QRZ or similar call will be allowed to count for points. If points are claimed for both sides of a QSO, the callsign of each must appear in the station-heard column.

Log sheets are available from Owen Cross G4DFI, 28 Garden Avenue, Bexleyheath, Kent DA7 4LF, England, if you include an SAE and sufficient return postage. If is desirable that entrants use official log sheets, but entries on homemade log sheets will be accepted if the following information is given: date, time, band station heard, station being worked, report at SWL's QTH. Points may be claimed only for stations actually heard and callsigns must be shown in full. Entries should be sent to the Contest Manager, G4DFI, at the above address, to arrive no later than November 1st. Certificates of merit will be awarded at the discretion of the board of the Cray Valley RS and its decision will be final.

WASHINGTON STATE QSO PARTY

0100 to 0700 GMT September 18
1300 GMT September 18 to 0700 GMT September 19
1300 GMT September 19 to 0100 GMT September 20

The seventeenth annual contest sponsored by the Boeing Employees' Amateur Radio Society (BEARS) is divided into three operating periods as shown. All amateurs are invited to participate. Use all bands and modes, but no CW QSOs are allowed in the phone bands. Stations may be worked once on each band and mode for contact points and more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number, RS(T), and state, province, country, or Washington county.

FREQUENCIES:

Phone—1815, 3925, 7260, 14280, 21380, 28580; CW—1805, 3560, 7060, 14060, 21060, 28160; Novice—3725, 7125, 21150, 28160.

SCORING:

Washington stations score 2 points for each phone contact and 3 points for each CW contact, including contacts with other Washington stations. Multiply QSO points by the total number of different states, Canadian provinces, and other foreign countries worked.

All others score 2 points for each phone contact and 3 points for each CW contact with a Washington station. Multiply QSO points by the total number of different Washington counties worked (39 maximum). There will be an extra multiplier of one for each group of 8 contacts with the same Washington county for all non-Washington stations.

AWARDS:

Certificates will be awarded to the highest scoring station (both single- and multi-operator) in each state, Canadian province, foreign country, and Wash-

ington county. Additional certificates may be issued at the discretion of the Contest Committee. Worked Five BEARS Awards also are available to anyone working 5 club members before, during, or after the QSO party (unless previously issued). All QSO Party entries will be screened by the Contest Committee for possible Worked Five BEARS Awards. Worked Three BEAR Cubs Awards are also available for working 3 Novice members.

ENTRIES:

Logs must show dates/times in GMT, stations worked, exchanges sent and received, bands and modes used, and scores claimed. Include a dupe sheet for entries with more than 200 QSOs. Each entry must include a signed statement that the decision of the Contest Committee will be accepted as final. No logs can be returned. Results of the QSO Party will be mailed to all entrants and an SASE is *not* required. Log sheets and summary sheets must be postmarked no later than October 20th and sent to: Boeing Employees' Amateur Radio Society, c/o Contest Committee, Willis D. Propst K7RS, 18415 38th Avenue South, Seattle WA 98188.

CAN-AM CONTEST

Starts: Phone—1800 GMT September 18
CW—1800 GMT September 25
Ends: Phone—1800 GMT September 19
CW—1800 GMT September 26

Sponsored by the Ontario Contest Club and Canadian DX Association to increase the friendship among Canadian and American amateurs and to provide a means of measuring the performance of operating skills and equipment. Categories of competition: single operator—allband, single band and QRP, stations operated by the station licensee; multi-operator, single transmitter—stations operated by more than one operator, or single operator other than the licensee, or club stations; and club competition. Multi-operator stations can operate full 24-hour period, single operator stations can operate maximum 20 hours with one or two rest periods totaling a minimum of four hours which must be clearly marked in the log. Any further rest periods do not need to be logged. For QRP operation, a maximum of 10 Watts input is allowed during the contest.

FREQUENCIES:

All SW bands 1.8 through 28 MHz are permitted. US General portion of the bands is recommended for use.

EXCHANGE:

Signal report: use RS on phone and RST on CW, plus sequential QSO number starting with 001, plus multiplier area (MX) abbreviation, in that order, i.e., 59001CT, 599021NY. Multiplier area abbreviation is the usual two-letter postal abbreviation for 50 US states, CN for Caribbean (KC4, KG4, KP1, KP2, KP4, KS4, KV4 and their A- and W- prefix equivalents), PC for Pacific (rest of US possessions and Antarctica). Canadians will use: NF for VO1, VO2; NB for VE1 New Brunswick; NS for Nova Scotia; PE for Prince Edward Isl.; SI for Sable and St. Paul Isl.; PQ for VE2; ON for VE3; MB for VE4; SK for VE5; AT for VE6; BC for VE7; NW for VE8 NWT; YU for VY1 Yukon.

SCORING:

The final score is the result of the total QSO points from all bands, multiplied by the sum of the multipliers from all bands. Phone and CW sections of the contest are considered separate contests. However, combined score for phone and CW will be used for overall competition. Combined score will be calculated by the contest committee as a result of the addition of phone and CW scores. Points: American to American, and Canadian to Canadian QSOs count for 2 points; American to Canadian and vice versa count for 3 points. The same station can be contacted once on each band and mode. Stations operating from outside of their own call area must sign slash and the area they are operating from, i.e., W6AM/7, NP4A/W4, W7RM/KH6, KH0AH/W6. Multipliers: 50 US states, 2 US possessions (Caribbean, Pacific); 10 Canadian provinces, 2 territories (NWT, YU), 1 islands (Sable, St. Paul). Total of 65 multipliers per band; maximum possible on all 6 bands is 390.

AWARDS:

Handsome first-place certificates will be awarded in each

multiplier area on both modes in single-operator category. Top five multi-operator stations in each country will receive certificates for high combined phone and CW scores. All scores will be published in CQ. Trophies and plaques will be awarded to the Canadian Champion and American Champion in four categories: single operator, combined, single operator, phone, single operator, CW, and multi-operator, combined.

The Club Competition Championship will be awarded to the club having highest score as a result of addition of 5 best scores on phone and 5 best scores on CW made by its members. A club officer must submit the summary showing the callsigns and scores. Each station is eligible for one trophy only. In a case where one station qualifies for another trophy, the less-significant trophy goes to the next eligible station.

Free one-year subscription to *Long Skip*, the CANAD-X bulletin, will be awarded to the top 5 US stations.

ENTRIES:

All times must be kept in GMT. Indicate multipliers the first time only on each band. Log must be checked for duplicate contacts, correct QSO points, and multipliers. Do not use separate logs for each band. Rest periods must be clearly marked in the log. Each entry consists of: log sheets, summary sheet showing all scoring information, category of competition, operator's name and callsign, address of the station, and signed declaration. Entries with over 200 QSOs must include check sheets for each band. Official logs, check sheets and summary sheets with multiplier tables area available from the Contest Chairman; a large SASE with Canadian stamps (or US stamps not glued to the envelope) will bring you the samples. Contestants are encouraged to use them; they greatly help with the processing of the entries. Send your log regardless of your score total.

Any band can be selected for the single-band category. All single-band entries will be judged in one category. It is up to the contestant to select the one that could bring him the highest point score for his particular situation.

Violation of national amateur radio regulations or rules of the contest, unsportsmanlike conduct, taking credit for excessive duplicate contacts, or unverifiable QSOs or multipliers will be deemed sufficient cause for disqualification. Incorrectly logged calls will be counted as unverifiable contacts. Actions and decisions of the CAN-AM Contest Committee are official and final.

All entries must be postmarked not later than 30 days after the contest and mailed to: CAN-AM Contest Chairman, VE3BMV, Box 65, Don Mills, Ontario, Canada M3C 2R6.

COLLEGE SCRIMMAGE

Starts: 0200 GMT September 18
Ends: 0400 GMT September 19

The idea of this contest is to put long-lost alumni in touch with their alma mater. Entry classes include alumni and college stations (one transmitter only). Exchange name of college, junior college, or university you last attended and the last year you graduated or will graduate. Club stations substitute "amateur radio club" for number. Non-collegians substitute "high school" for college name. Stations may be worked once per band on SSB only. Multiply total QSOs times number of different colleges, junior colleges, and universities worked. Logs should be sent to Penn State ARC, K3CR, 202 Engineering Unit E, University Park PA 16802. Please include an SASE for results.

NEW MEXICO QSO PARTY

Starts: 1800 GMT September 18
Ends: 2100 GMT September 19

Sponsored by the Albuquerque DX Association. Each station may be worked once on each band and each mode.

EXCHANGE:

RS(T); QSO number starting with 001; and state, province, DX country, or NM county.

SCORING:

Count 2 points for each phone/SSB QSO and 3 points for each CW QSO. NM stations multiply total QSO points by total number of states, provinces, and DX countries worked. All others, multiply total QSO points by the total number of NM counties worked each band, each mode.

AWARDS:

Plaques will be presented to the top score from outside NM and the highest NM single operator and portable. Certificates awarded top scorers from each state, province, and DX country. Certificates will also be awarded to each station submitting a score of more than 100 total points.

ENTRIES:

Entries must be postmarked no later than October 15th and addressed to: K5QQ, 1005 Morina Court NE, Albuquerque NM 87112. Include an SASE for complete results.

1982 MAINE QSO PARTY

Starts: 2300Z September 25
Ends: 2359Z September 26

The Maine QSO Party is sponsored by the Portland Amateur Wireless Association. Exchange signal report, serial number, and QTH (county for Maine stations; state, province, or country for others). Stations may be worked once on CW and once on phone for each band. Count three points per QSO and multiply by number of Maine counties worked for final score. (Maine stations multiply by Maine counties, states, provinces, and countries.) Suggested frequencies: CW—1805 and 60 kHz up from low end of band; phone—1815, 3930, 7280, 14280, 21380, 28580 kHz; Novice—3720, 7120, 21120, 28120.

Certificates will be awarded to top scorers in each state, province, country, or Maine county. Mail entries by December 1st to PAWA, Box 1605, Portland ME 04104. Applications for the Worked All Maine Counties Award may go to the same address.

MASSACHUSETTS QSO PARTY

Starts: 1600 GMT September 25
Ends: 0200 GMT September 27

Sponsored by the Greater New Bedford Contesters. A station may be worked once per band. Phone and CW are separate bands. No crossband or repeater contacts permitted. Mobiles and portables may be counted as new contacts each time a county change takes place.

EXCHANGE:

RS(T) and state, province, or Massachusetts county.

FREQUENCIES:

Phone—1820, 3960, 7260, 14290, 21380, 28590, 50.110; CW—1810, 3560, 7060, 7120, 14060, 21060, 21120, 28060, 28120. Use of FM simplex is encouraged. Remember to use CW in CW bands only.

SCORING:

All stations count 2 points for each completed SSB exchange and 4 points for each CW exchange. Massachusetts stations multiply QSO points by total number of states, provinces, and Massachusetts counties worked. DX stations worked only count for QSO points. Outside Massachusetts, multiply QSO points times total number of Massachusetts counties worked. As a bonus, add 100 points to the total score for each sponsor worked (KA1GG, N1AVA, K1KJT). Note that they can only be worked once for bonus points.

AWARDS:

Certificates will be awarded to first through third place winners in each Massachusetts county as well as each state. Two special awards will be given out for the radio club with the highest aggregate score in Massachusetts (min. of 3 logs) and to the Massachusetts station submitting the all-time highest number of QSOs. The current record is held by K1GSK (1483 QSOs in the 1979 contest). Additionally, a certificate will be given stations working all three sponsors.

ENTRIES:

Logging must include date/time, band, mode, callsign, state and province worked, and exchange RS(T). Submit separate summary sheet along with logs. Summary sheet information should include your name, call, mailing address, club affiliation for aggregate score, total QSO points, multipliers claimed, and total score. Deadline for mailing is October 31. For awards and results, send $.50 postage (no envelope) to Ed Peters K1KJT, 29 Greenbrier Drive, New Bedford MA 02745.

ISKRA II

By the time you read this, the ISKRA II satellite placed into orbit by cosmonauts aboard the Salyut VII space station probably will have reentered the atmosphere and met its fiery fate. The projected lifetime of ISKRA II was only six weeks from the time of its launch on May 17.

ISKRA II was unique in being the first amateur satellite to carry an HF-to-HF transponder. It received signals on 15 meters and retransmitted them on 10 meters.

FUN WITH RS TELEMETRY

With rare exceptions, a satellite orbiting the Earth is beyond the reach of direct human observation. We can't see it, except perhaps as a bright dot in the night sky. If it misbehaves, we can't put it on the test bench to determine what ails it. In fact, the only way we have any idea of the condition of an orbiting satellite is by means of the telemetry data it constantly beams to Earth.

In the excitement over the communications opportunities offered by the six RS satellites launched last December by the Soviet Union, the interesting telemetry beacons of these spacecraft have largely been overlooked. Monitoring these beacons can be an interesting activity that does not require any special equipment. You need only the ability to receive signals at the high end of the 10-meter band.

Satellite	Beacon Frequencies (MHz)
RS3	29.321, 29.401
RS4	29.360, 29.403
RS5	29.331, 29.452
RS6	29.411, 29.453
RS7	29.341, 29.501
RS8	29.461, 29.502

Table 1. RS beacon frequencies.

The RS satellites send their telemetry in Morse code at 15-25 words per minute on the beacon frequencies shown in Table 1. Each frame of telemetry consists of seven items of information, and consecutive frames are separated by the name of the satellite. Thus, a telemetry frame from RS3 might read: RS3 K00 D12 O72 G00 U21 S79 W90. The letter prefix designates the parameter being measured, while the two-digit number represents the measured value. Often, the number must be inserted into a simple equation to translate the measurement into standard units.

A given satellite may send up to 28 different telemetry items, organized into 4 frames, before it repeats the entire sequence. Most items have a two- instead of one-letter prefix ahead of the number. Two-letter items with the same first letter are always sent as part of the same frame.

Table 2 contains a list of the telemetry prefixes so far monitored from the RS satellites, along with equations and other information.

By interpreting the telemetry data, you can learn a great deal about the environment aboard the RS satellites. It's one way to take an active part in the amateur space program even if you're not equipped for two-way satellite communications. Shortwave listeners can participate, too. Give it a try!

Prefix	Interpretation
K	0.2 × N = output power of transponder in mW
D	N × 0.2 = voltage of main power source
O	20 × (100 − N) = charge current in mA
G	telemetry baseline; should be zero (00)
U	gas pressure of sealed system; equation unknown
S	N = temp. of voltage regulator (Celsius)
W	N = temp. of transmitter cooling fins (Celsius)
IK or SK	same as K
ID or SD	telemetry baseline; should be zero (00)
IO or SO	0.2 × N = output power of beacon in mW
IG or SG	when N = 10 ± 1, a 10-dB attenuator is in line with main receiver front end
IU or SU	0.1 × (N − 10) = S-meter reading of 1st receiver
IS or SS	same as above for "robot" receiver
IW or SW	same as above for 2nd receiver
NK or RK	same as K
AK or UK	same as K
AD or UD	0.1 × N = voltage of transponder 9-volt line
AO or UO	" = voltage of transponder 7.5-volt line
AG or UG	" = voltage at first 9-volt stabilizer
AU or UU	" = voltage at first 7.5-volt stabilizer
AS or US	" = voltage at second 9-volt stabilizer
AW or UW	" = voltage at second 7.5-volt stabilizer
MK or WK	same as K
MD or WD	N = # of QSOs made by robot (occasionally reset to zero by ground controllers)
MO or WO	N × 0.1 = power consumption of heating system in Watts
MG or WG	N × 20 = input power of robot transmitter in mW
MU or WU	N × 20 = input power of service channel in mW
MS or WS	when N = 10 ± 1, a 10-dB attenuator is in line with the robot receiver front end
MW or WW	when N = 10 ± 1, a 10-dB attenuator is in line with the service receiver front end

Table 2. RS telemetry channel prefixes and their meanings. N is the two-digit number sent after the prefix. Where two prefixes are given, the first is used when the transponder aboard the satellite is inactive; the second is used when the transponder is active. The definitions of other prefixes are not yet known.

CORRECTIONS

"Coherent CW for VHF," which appeared in the July, 1982, issue, was based on a paper given at the 27th Annual VHF Conference, Western Michigan University, Kalamazoo MI, on Oct. 17, 1981.

Tim Daniel N8RK
***73 Magazine* Staff**

Following the publication of "The Very, Very Best CW Filter?" (*73 Magazine*, July, '82), some builders have written me to tell of oscillation in the output of this filter. This is probably due to an "induced" feedback to the input of the very sensitive op amp used in the circuit.

Rather than rearrange the components, it is easiest to control this oscillation by putting a small amount of positive bias on the input. Connect pin 2 of the LM324 to the positive voltage through a resistor of about 200k Ohms. The exact size of the resistor is best determined by experimentation. If the resistor is too small, the sensitivity of the unit will suffer; if the resistance is too large, some oscillation may remain.

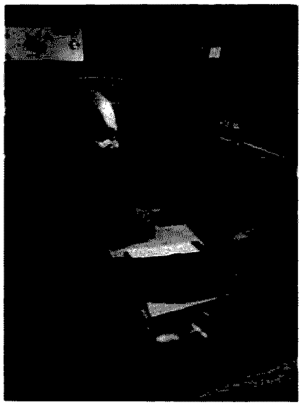
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



THE OLD MAN

With my 60th birthday coming up September 3rd, I find myself retrospecting . . . and wondering how much time is left. I can't complain, for I've enjoyed putting out *73 Magazine* for the last 22 years and I've had the excitement of being there when many of the interesting things happened.

Back when I first got into amateur radio, I used to go to the hamfests and be amazed at Ted McElroy and his ability to copy high-speed code. What a show he put on! He'd tune in some code at around 50 wpm and talk with the people around him for awhile, then turn to his typewriter and make it sound like a 100-word-per-minute Teletype™ machine. As I recall, Ted not only was the fastest man in the world in copying code, but I think he had some speed records in typing, too. Heady stuff for a kid.

Then, soon after the war, I happened to be in the right place at the right time to participate in some of the early narrowband FM experiments. I modified an old SCR-274 transmitter and a Meisner Signal Shifter with reactance modulators and had a ball. Of course, I'd been building ham gear since 1937 (golly, that's 45 years ago!), so my ham shack was piled high with equipment by 1946. I still have hams say hello at hamfests who visited my shack in those days and marveled at the collection of things I'd bought (surplus) and built. I loved to build.

The true old-timer is the chap who made tube socket holes in steel chassis by first drilling a small hole and then enlarging it with a rat-tail file for the socket. Oh, there were socket punches, but they were darned expensive. It was a long time before I managed to buy a set of those elite tools.

Then there was John Williams W2BFD, the grandpappy of ham RTTY. Oh, others helped, but it was John that really got it all started. He did most of the early experimenting, arranged to get the equipment, distributed it, and wrote articles about it. It was his work that got me going on RTTY in 1948, which in turn got me to start a RTTY magazine back in 1951. I've been editing and publishing ever since. John was a cranky, sneaky old man, and he was a good friend. It's a shame he died in 1961, for he would have loved solid state and ICs. But he didn't take care of himself (smoked), so one day he keeled over. He lived and died for amateur radio.

Then there was Sam Harris W1FZJ, another irascible genius and a good friend. Sam made the first practical parametric amplifier. He also did a lot of the early moonbounce hamming, culminating in his working for the big dish folk at Arecibo.

On the other side of the coin, I had the fun of knowing Don Miller rather well . . . and getting sued by him when I blew the whistle on his false DXpeditions. I've never written the entire story of *that* one, but I should. No, that's not the same Don Miller that got shafted by the League a couple years ago . . . different chap. The older Miller is, I believe, in prison in California for trying to get some chap to kill his wife. The League Miller is, I understand, about to run for director again. That should be an interesting election. Since, as far as I could discover, he was kicked out of the job on a trumped-up charge, I'd like to see him win this one. And I say that despite some of the unkind things Don has said about me at ham clubs.

Even after 45 years of ham radio, I still get a kick out of getting on 20m and making contacts . . . either around the US or with some good DX. A couple years ago I was out there climbing our mighty Mount Monadnock to get at the head of the line for 10-GHz DXing, with seven states contacted. No one has come close to equalling the record yet. That was hard work . . . and fun. I think the mountain climbing may have taken a year off my life . . . but that is nothing compared to the dent my first wife made in it.

Just managing to survive with *73* for all these years has been a miracle. Remember that I'd just really gotten started with it when the "incentive licensing" debacle hit in 1963 and stopped the growth of amateur radio for 10 years. That's when three-quarters of the ham dealers and 95% of the manufacturers went out of business. At one time the magazine staff was down to five people, working day and night to try to keep things going.

With the ham industry picking up a bit due first to FM and repeaters and then from an influx of CBers, I kept things going. The invention of the microcomputer sparked me to start *Byte* magazine . . . and then *Kilobaud*, Instant Software, *Selling Micros*, *80 Micro*, Load 80, and *Desktop Computing*. We went from a few people to a staff on the order of 250, with buildings all around town. We still have more magazines in the works with no end in sight.

One of the benefits of getting the business to this size is that my ideas have a better chance of getting attention. I suppose that at 60 I should start to slack off and not work so hard. I still put in a hundred-hour work week and keep up with reading some 200 or so magazines a month . . . plus a few books. Add that to my travel schedule to hamfests, computer shows, and to give talks. I count 18 shows so far just this year, nine talks, several Washington trips for NIAC, a couple of consulting trips, and a short visit to Colombia. Not bad when you consider we're only into July at this writing.

Yes, partly I'm bragging. But that isn't all of it. I do want you to know that I'm doing all this with a goal in mind of providing you with a magazine which is interesting, which will, I hope, inspire you to enjoy amateur radio more, and which may bring education to more of the world. I feel that I'm doing the best I can and I hope that you'll help me towards my goals with subscriptions, with articles, and by getting youngsters into amateur radio.

Though I've got a wonderfully supporting bunch of people working with me, we need more help. We're getting a big new magazine started this fall and would like to start some more next year, if we can get the people to help with the work. We have a wondeful bunch of people who are enjoying what they

ATTENTION, AUTHORS!

73 Magazine is always searching for good articles, and now may be your chance to share the fame and fortune enjoyed by hundreds of other readers-turned-authors. We are looking for construction articles, antenna articles, club project articles, and so forth. Articles on any subject dealing with amateur radio are considered, but our primary emphasis is on construction. If you need help in getting your manuscript up to snuff, we will send you a copy of "How to Write for *73*" (free for an SASE). Please send your request or manuscript to: Editorial Offices, *73 Magazine*, Peterborough NH 03458.

do...and are learning. There isn't a better part of the whole world in which to live than New Hampshire.

While I enjoy publishing the magazines, my main goal is to try to get American technology so we can catch up with Japan. To this end I believe we need a monumental growth of amateur radio, attracting the teenagers to the hobby. Then we need better colleges to teach them and turn them loose to build new businesses and provide us with the telecommunications and computers we are going to need in the next ten and twenty years.

With your help, I think we can get the amateur rules so they are better in tune with the type of technical enthusiast we need. With your help, we can get ham clubs going in every high school in the country. With your help, we can set up a pilot model of the college that is needed... and then help it proliferate. Has anyone franchised colleges yet?

At Comdex, the computer show in Atlantic City a couple of weeks ago, I was most pleased to meet so many computer company presidents who walked up to me and gave me their call letters. I wasn't surprised, for amateur radio gives a youngster a tremendous head start over everyone else when it comes to a technical career.

I've got to lose about ten pounds I put on eating at the shows and I've got to spend some time getting in shape for skiing this winter. That, plus getting a new magazine going and hitting the show circuit again this fall, should keep me busy. Do I hear any interest from readers in joining me on the show trip to Tokyo, Seoul, Taipei, Hong Kong...and on to 9V1, 9M6, VS5, 9M8, DU?

THE NON-DXPEDITION

Some 700 DXers who worked KF1O portable on CE0X on San Felix Island (off Chile) were somewhat upset recently when the League discredited the operation. One of the DX bulletins had further details. It was reported that the Chilean government had claimed the documents as forgeries. The Chilean club was up in arms about the whole situation.

A day or so later I received a letter mailed from Greece from Bob Read KF1O with copies of some CE0X documents but no explanation. These papers were copies of copies, so there

The most common way to abuse a sideband signal at the transmitter is by overdriving the output amplifier. That generates splatter, spurious signals which can cause interference up to 50 kHz or more from the normal transmission frequencies.

The "Splattometer" connects easily into the transmission line, monitors the output signal, and flashes a warning lamp whenever it detects flattopping. An entirely new type of signal analyzer, it is a real help in getting the most power from a transmitter while minimizing splatter. The entire instrument, including the built-in ac power supply, can be built for $65 using all new Radio Shack components, or for much less if your junk box isn't completely empty.

Amplifiers used in sideband transmitters are linear amplifiers. That means the output signal, aside from being more powerful, should be an exact replica of the input signal. Amplifiers have limits, however, and overdriving one can cause it to exceed its linear range so that the peaks of the output waveform get clipped or flattened. These flattops cause the signal to splatter extra energy onto adjacent frequencies.

Splatter can be hard to control for several reasons. Operators naturally want to run their transmitters at full power, and that often leads to running the microphone gain too high. An swr-type power-output monitor will show more output power, but unfortunately much of that extra power is spread up and down the band.

Monitoring a transmitter for splatter until now also has posed a problem since it required the use of an oscilloscope. That solution can be complex and expensive. As a compromise, most hams leave the microphone gain control set at some customary point and hope the ALC is working well enough to avoid splatter. For some people that works and for some it doesn't. It usually doesn't work at club stations where operators may not be too familiar with the equipment, and it usually doesn't work during contests when the race is on and every Watt counts.

Photos by W1GSL

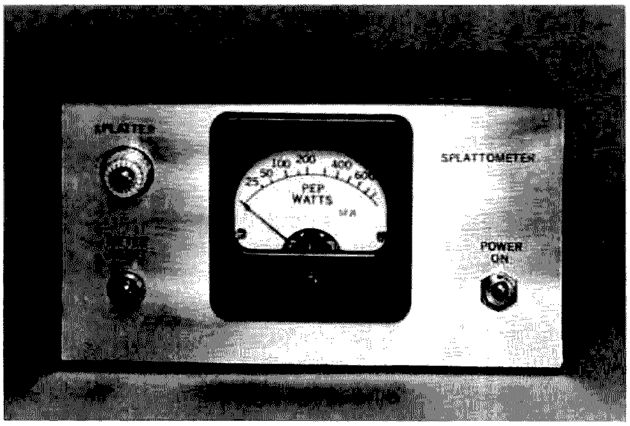

Photo A. The uncluttered 4" by 7½" front panel is dominated by the PEP wattmeter and splatter-alarm lamp. Only two operating controls are required, a power switch and reset push-button.

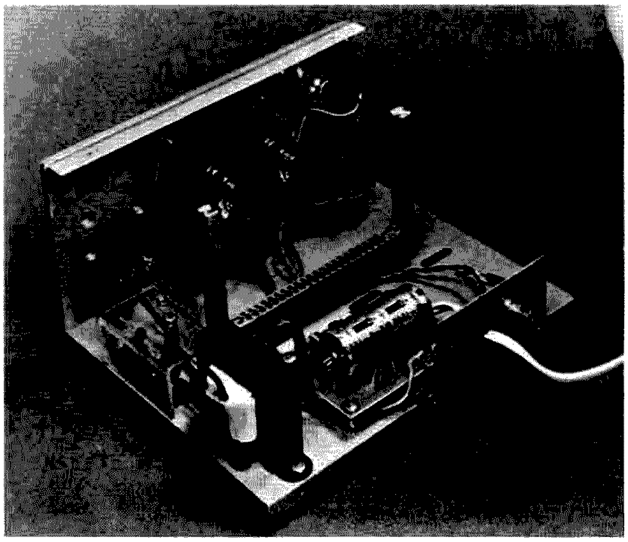

Photo B. Interior view of the recycled cabinet. The main circuit card plugs into the empty card socket while the power supply is mounted separately. Note that the rf voltage divider resistors are mounted directly on the input connector. A plastic shield keeps stray fingers off the ac line fuse.

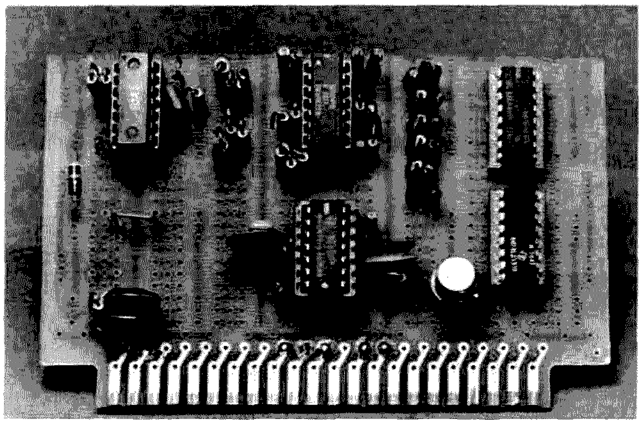

Photo C. *Five ICs and the lamp driver transistor pack a lot of functions into a small space. The rf detector/filter components are grouped by themselves in the lower left-hand corner of the board. From left to right across the board are the quad op amp, quad comparator and dual timer, and finally the two up/down counters. One-quarter Watt resistors and miniature capacitors are mounted on end to save space.*

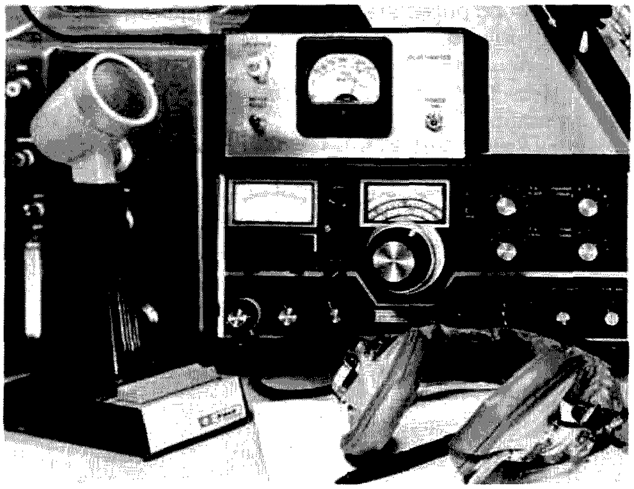

Photo D. Although it fits nicely on top of the transceiver, the Splattometer can be placed anywhere within the operator's field of view. It doesn't need constant attention; when you splatter, it lets you know with a bright flash.

The "Splattometer" is a much better alternative. This simple flattop-monitor and -alarm circuit is usable over a wide range of transmitter power levels. The circuit basically consists of two sections. The first measures the peak voltage present in the transmitter signal. The second section measures how long the transmitter output has been at that maximum level. A clean SSB signal will just peak briefly to the transmitter's maximum output, but a splattering signal will be clipped and so stay at that level for a longer time. That time at maximum power is detected by the circuit and triggers the splatter indicator.

How It Works

A block diagram of the circuit is shown in Fig. 1. The antenna cable is looped through the unit and a small portion of the rf voltage is sampled with a restive divider. This signal is rectified and lightly filtered to create an accurate audio frequency reproduction of the rf envelope.

The peak-voltage measuring portion of the instrument is built around an up/down counter and simple six-bit digital-to-analog (D/A) converter. The converter output is a dc voltage nominally equal to the peak level of the detected rf waveform. If the detected level peaks higher than the existing D/A output, the counter gets clocked a step higher, thus raising the D/A output voltage. This feedback-controlled up-counting by itself would eventually set the converter output just above the rf peak voltage.

The counter, however, is also being clocked downward about two steps every second; as a result, the D/A converter output tracks within one or two steps (about .2 volts) of the detected peak envelope level. A threshold circuit freezes the counter state when the rf signal disappears between words, sentences, or transmissions. The dc measurement of the peak signal level also drives a simple voltmeter whose scale is calibrated to show the PEP Watts the transmitter is delivering to a 52-Ohm load. Notice that the relatively crude 6-bit D/A converter is perfectly acceptable since the feedback around the counter automatically adjusts the dc output to match the peak input. The actual counter state and converter linearity simply don't matter.

The flattop-detection portion of the Splattometer starts by low-pass-filtering the detected rf envelope with a one-millisecond time constant. This means that if the rf envelope suddenly jumps from zero to maximum, the filter outputs will take about three milliseconds to follow it. The splatter indicator is triggered whenever the output of this filter is greater than 80% of the measured peak signal level. The 80% and 1-ms time constant were chosen so that the instrument will detect any flattop lasting longer than 2 ms.

The output indicator is a panel lamp driven by an IC timer which generates a .1-second-long pulse whenever a flattop is detected.

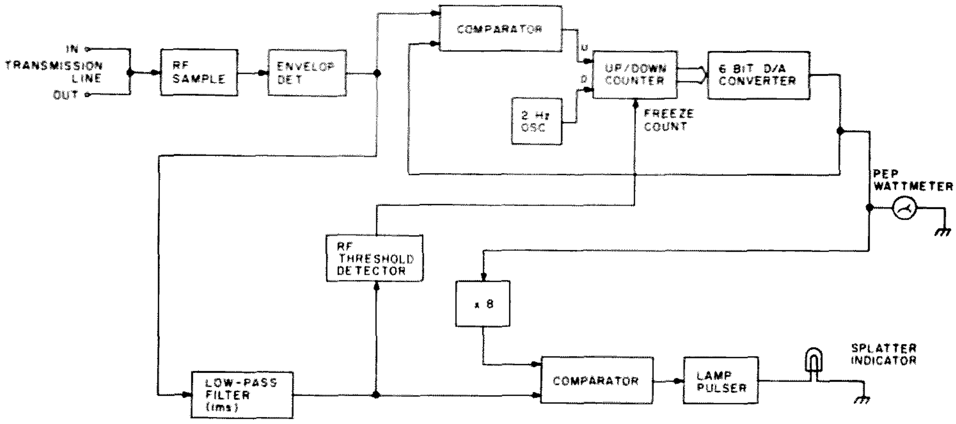

Fig. 1. Splattometer block diagram.

The .1-second pulses are just long enough to produce a bright eye-catching flash on each detection. This visual alarm works well.

One of the nicest features of the Splattometer is that you don't have to concentrate on watching it the way you would an oscilloscope. It just sits quietly off to the side until you start talking too loudly and then *Flash!*, it grabs your attention. A useful modification of the output indicator, particularly for sightless hams, would be to replace the lamp with a 4.8-kHz piezoelectric buzzer. The operator would certainly hear the buzzer, but its frequency would be too high to get past the transmitter's SSB generator.

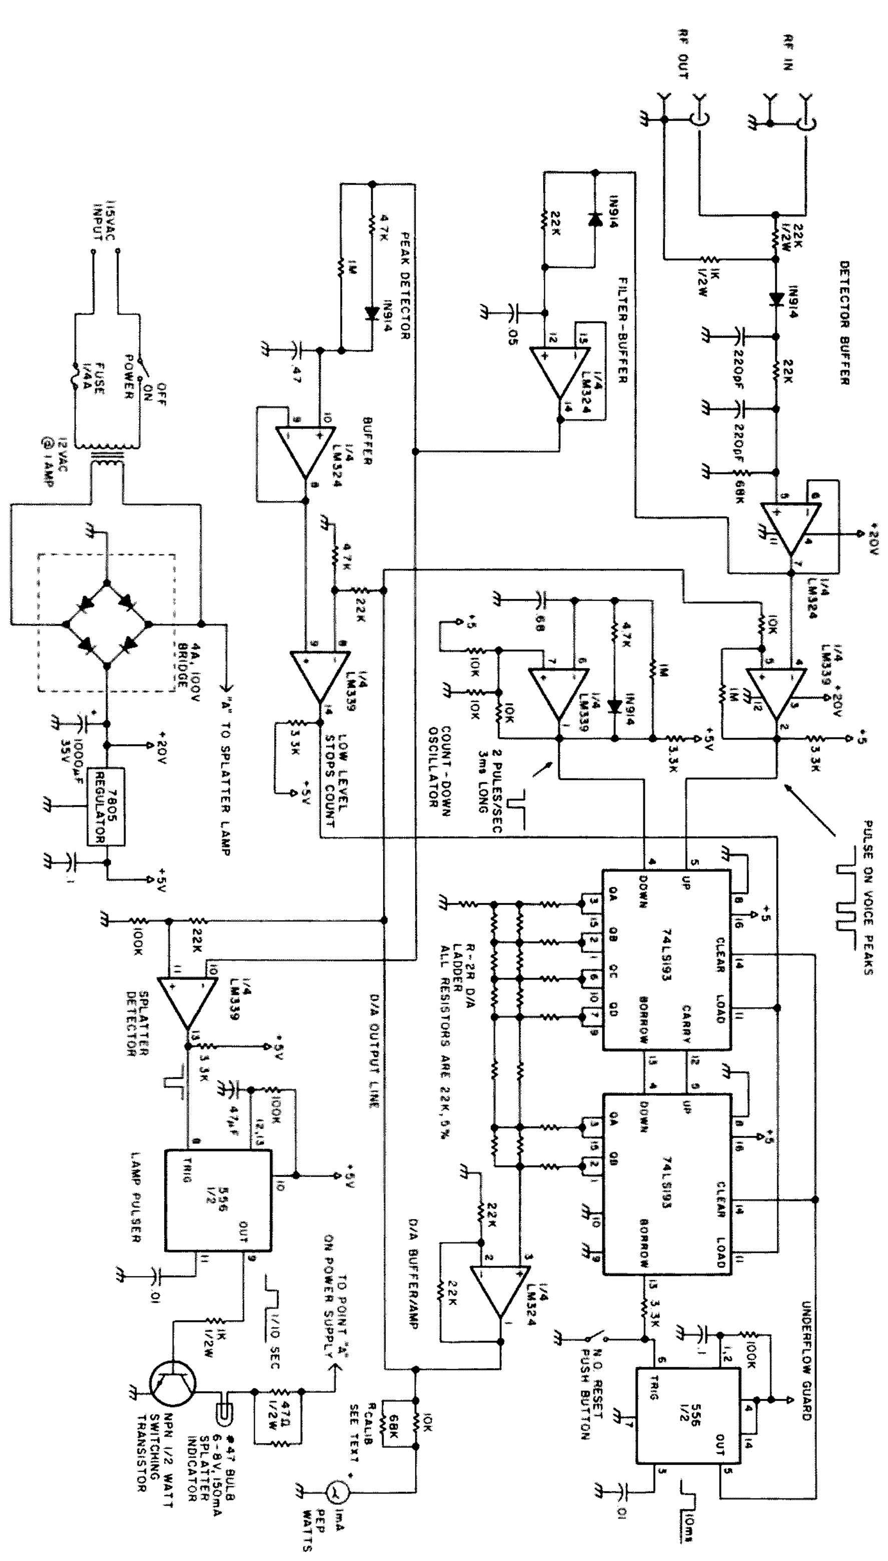

Fig. 2. Schematic diagram.

The complete circuit diagram is shown in Fig. 2. The circuit proper uses just five ICs, and the power supply contains a sixth for 5-volt regulation. An LM324 quad op amp is used to buffer the several RC filtered signals and acts as the D/A output amplifier. A quad LM339 comparator gates the counter-up, counter-hold, and splatter-detection signals. The last comparator section is used in the 2-Hz countdown oscillator. One section of a 556 dual timer generates the output indicator pulses while the other prevents the counter state from underflowing from zero to all ones. That second timer section can also be triggered by the front panel push-button to reset the counter to zero. The reset button isn't used much except at power turn-on when the counter is likely to come up in an unrealistically high state.

The counter uses two 74LS193s. The standard 74193 chips will work just as well, but the extra 10¢ cost per chip seemed like a worthwhile expense in terms of reduced power consumption. The D/A converter is an R-2R ladder made entirely with 22k resistors. Five-percent resistors were used without problem, although the conversion linearity is poor. That doesn't matter, as mentioned earlier, and the 64 output levels are adequate for proper circuit operation.

The simple power supply has one unusual feature. The main circuit board requires 12 to 20 volts at 10 mA or so and 5 volts at 45 mA. Those needs are easily met with the 1000-uF filter capacitor and the 5-volt regulator. The indicator bulb draws about 150 mA, though, and if taken from

the 20-volt supply, this is enough to drop the filtered dc level several volts and significantly increase the ripple. As an alternative, the bulb is powered from the half-wave rectified voltage present between ground and either input side of the bridge. The rms level there is a better match for the bulb's design voltage, and the bulb current has little impact on the 20-volt supply since it is isolated from the filter circuit. The two 47-Ohm resistors in series with the bulb limit the current so that the lamp brightness is about the same as when powered from a true 6-volt source.

Construction

As can be seen in the photographs, my unit makes liberal use of flea-market components. The parts list specifies equivalent Radio Shack parts which can be used to build a similar-looking unit. Total cost using all Radio Shack parts is around $65, but there are many corners which can be cut to reduce that price.

My flea-market cabinet is a real deluxe job, so the parts list specifies a correspondingly nice $9 unit. A similar-size Bud Minibox or other enclosure would work as well and cost much less.

The Radio Shack meter also costs $9, but many surplus outlets having advertisements in *73* regularly offer similar meters at less than half that price.

My junk box contained a salvaged plug-in-type circuit board and socket; those two items purchased new total almost $7. Obviously the plug-in feature is nice, but it is also completely unrelated to the electrical operation of the circuit.

Radio Shack components are of reasonable quality and readily available, so they are a good yardstick to use in measuring the maximum cost of this project. Remember, however, that with a little resourcefulness, the cash outlay can be substantially reduced.

Using Radio Shack component values is also sometimes difficult. The R-2R ladder in my unit is actually constructed with 10k and 20k resistors. The schematic and parts list specify 22k resistors because they were in the Radio Shack catalog, but using only that size requires paralleling 5 extra resistors to create the 11k values. Electrically that's perfectly acceptable, but physically it's somewhat bulky. If you do buy the 22k resistors, the entire project uses 23 of them. Since only 17 go in the ladder network, be sure to use the opportunity to select out the closest matched group of 17 with an ohmmeter.

You'll see in Photo B that I used a single rf connector while the schematic shows a two-connector loop-through. I run the transmission line right by the back of the instrument and use a tee connector to connect to the input of the Splattometer. The two-connector loop-through is preferable as it avoids completely the temptation to connect the instrument to the line with a single length of cable, cable which would look like a reactive stub on the higher bands and so interfere with transmitter tuning.

Note also that the resistive divider is mounted directly on the back of the input connector. That minimizes stray coupling problems by keeping the large rf voltage away from the main circuit board.

For the same reason, the rf detector and filter components are grouped by themselves in one corner of the main board. I mounted the ac fuse inside the box since the back panel opening on my cabinet wasn't large enough for the ac line, rf input connector, and fuse, too. The parts list specifies a panel-mounted fuseholder since most people won't have my space problem.

The simple power supply is built as a separate unit. Certainly that handful of parts could be placed on the main board with the rest of the circuit. The advantage of the separate approach is that is is easier to disconnect and test the power supply by itself. It's also convenient to be able to insert current meters between the supply and main circuit during checkout.

The front panel can be laid out in any desired manner. Try to choose a lamp holder which will easily be visible over a wide angle. One advantage of the flashing indicator is that it can attract attention without being constantly watched. Don't ruin that feature by using a lamp assembly which has a narrow viewing angle. I didn't include a power-on indicator lamp on the assumption that it might lessen the visual impact of the splatter indicator.

The PEP wattmeter is actually a dc voltmeter reading 0 to 8.5 volts, so any dc current instrument with a full-scale range of 5 mA or less will work with a suitable selection of series resistor. The rf sampler and filter circuits of the Splattometer are designed so that a 3-volt dc output at the D/A converter corresponds to 100 Watts PEP delivered to a 52-Ohm load. Power is proportional to voltage squared and the D/A output can range from almost zero to 7.5 volts, so the meter will read from near zero to about 700 Watts PEP. Meter calibration is quick and easy using the calibration chart shown in Fig. 3.

I made a whole new face for my junk-box meter using India ink, press-on transfers, and a piece of good writing paper pasted to the *back* of the old metal meter face. The back of the metal plate

A SPLATTER DETECTOR FOR PROCESSED AUDIO?

Several people have independently suggested how to build a splatter detector which might work with both processed and natural audio. The suggested technique is certainly worth passing along as a guide to further experimentation. The idea is to identify the sharp clipped corners which cause splatter by doing some frequency analysis on the AM-detected SSB envelope. In this approach, the output of a lightly filtered AM detector would be separated into two channels—one each for frequencies above and below 3 kHz. Ideally, the signal filtered into the low-pass channel would be all "good" energy while the high-pass channel would contain only splatter signal. These two audio channels could then themselves be rectified, filtered, and compared in magnitude to provide some measure of the amount of splatter at any given time.

I see two main problems with this approach, one practical and one theoretical. First, the low-pass and high-pass filters may be difficult to design in an easily reproduced form. There will be a lot of signal in the low-pass channel, but not much in the high-pass section: perhaps 30 to 50 dB of rejection will be required over a small (less than an octave) frequency range. Each channel will probably need three or more cascaded active filters with closely matched cut-off frequencies, Q, and passband ripple. Second, the high-pass channel will also contain signals not caused by splatter—the 3rd and 5th order distortion products—and these signals may confuse the splatter-detection process. Their presence certainly adds an interesting element to the trade-off between time and frequency domain analysis. The detection approach outlined in Fig. 1 has a lot of positive features: it works fine with unprocessed audio, is auto-adaptive over a wide range of input levels, is easily reproduced, and is low in cost. The processed audio problem is ripe for experimentation and perhaps some readers would like to give it a try.

Rf Input Power Level (Watts)	D/A Output Voltage	Meter Reading (If full scale is 1.0)
25	1.5	.177
50	2.12	.25
100	3.00	.353
150	3.67	.432
200	4.24	.50
300	5.20	.612
400	6.00	.707
500	6.71	.79
600	7.35	.866
700	7.94	.935
800	8.49	1.00

Fig. 3. Meter calibration points.

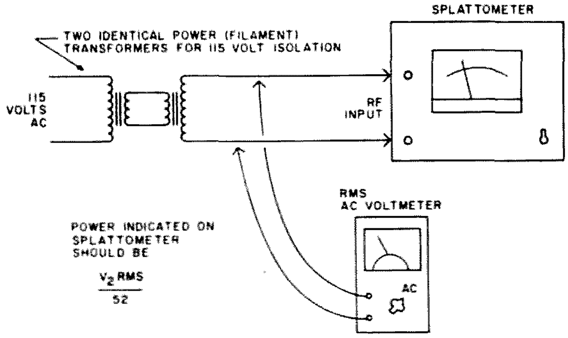

Fig. 4. Calibration using the 115-V, 60-Hz line.

is blank, of course; the original scale would show through paper glued to the front of the faceplate. To make the scale, draw an arc on the new meter face, replace the faceplate and connect the meter to a variable power supply through a resistor sized to make 8.5 volts read full scale. With a 1-mA meter, that resistor should be just under 8.5k. The schematic shows a 10k resistor in parallel with a higher value; 56k will do the job almost exactly. If you purchased the Radio Shack resistors, there will be a spare 68k, ¼-Watt resistor which will work fine.

With the chosen resistors in place, set the supply to 8.5 volts and mark that pointer position as 800 Watts. Now go down through the middle column of Fig. 3 marking the wattage levels at the corresponding voltage points. Finish up by removing the faceplate and adding the dry transfer numbers at the appropriate spots. If you don't want to go through the trouble of making a new meter face, the third column of Fig. 3 can be used to make a conversion chart for the existing scale on a 1-mA instrument.

For convenience, I built the main circuit on a plug-in prototype card. This board comes drilled with .1-inch spaced holes and has an array of printed circuit pads etched on one side. The IC sockets and passive components are mounted on the front of the board and the interconnections are made from the rear with short lengths of wire. Wire-wrap wire is nice to use for the wiring because of its small size. The finished board doesn't look as nice as a real printed circuit card, but it is quicker to make, works as well, and is easier to modify should a reason arise. If you wish, you can save some money by skipping the plug-in feature and hard-wiring the necessary external connections to a standard prototype board.

Checkout and Operation

There is nothing critical about this circuit that has to be "tweaked" in to allow proper operation. If the project doesn't work when first turned on, the reason is most likely a wiring error or sloppy soldering, so check your work carefully. It is always prudent to try the power supply first, making sure the proper operating voltages are there. With everything connected, the meter will probably read upscale when the power is switched on. This is because the counter stages turn on in some random condition. Pushing the reset button should drop the meter pointer almost to zero.

Connect a transmitter through the unit to a dummy load and tune up for normal SSB operation. To maintain calibration accuracy, the Splattometer should always be inserted in the line at a low swr position, that is, between the transmitter and antenna coupler if one is used. Push the reset button after tuning up, key the transmitter, and say a few words into the microphone. The splatter lamp will flash on the first few syllables and the meter will move rapidly upscale. The Splattometer has now calibrated itself to your transmitter's PEP output and is watching for flattopping. The meter will flicker only slightly as you continue to talk; between words and transmissions it will hold dead still. The typical efficiency of a linear amplifier is around 60%, so if the transmitter is rated at 200 Watts PEP input, the meter should indicate about 120 PEP Watts output.

Now turn up the microphone gain, talk more loudly, or cluck into the microphone. The splatter lamp will flash but the PEP output meter won't move upward any more than when you were talking normally. If you have an swr bridge or averaging power meter in the line, you'll notice that it *does* indicate more power when you flattop. A lot of amateurs make themselves unpopular because they don't realize some of that "extra" power is just splatter.

Incidentally, during CW operation the splatter lamp will flash on every key closure since the CW signal is detected as a severely distorted SSB signal!

One limitation of the Splattometer circuit is that it may not respond properly when speech processing is used. This failure results from assuming that splatter is always associated with an extended period of maximum transmitter output. The splatter isn't *generated* during the clipped interval, however; it's really a result of the sharp transition between the flattop level and the rising (or falling) envelope power at the beginning (or end) of the clipped peak. Key clicks on a poorly-shaped CW signal are caused in exactly the same manner. When normal unprocessed audio is used to generate the SSB signal, any peak clipping would be expected only in the output amplifier, so in that case splatter and limiting go together and the Splattometer will work beautifully.

With processed audio, the situation is different. Speech processors, whether designed to work at audio or rf, generally contain somewhere in their makeup a compression amplifier, clipper, and filter. The amplifier brings up the relative amplitude of the weaker voice sounds, the clipper limits the peak output level, and the filter removes the high-frequency distortion products caused by the clipping action. The SSB envelope produced with processed audio can have flattened peaks holding at the maximum output level for relatively long periods of time. Such peaks do not in this case indicate the existence of splatter because the clip-

Reader Service for facing page ↙15→

ping occurs in the speech processor (where it is also "cleaned up" with a filter) and not the transmitter's final amplifier. The Splattometer will detect these peaks and incorrectly indicate the signal is splattering.

This shortcoming is really not the handicap it first appears to be. Once the clipping level in the processor is correctly set, that circuit will prevent the transmitter output stage from being overdriven into saturation—no matter what happens at the microphone. Increased audio input to the processor or increased amounts of compression will raise the average output power (and the amount of distortion in the audio recovered at the distant receiver), but the *peak* input to the final amplifier will be safely limited by the processor's clipper and splatter will not occur. The Splattometer is needed most in the situation where it works best: an SSB transmitter running with unprocessed audio. In that case, clipping is most likely to occur in the transmitter's output stage. Such clipping will cause splatter and the Splattometer will correctly identify the condition.

The final wattmeter accuracy is dependent on several things but should be within 10 or 15 percent without further adjustment. If you're really finicky about such things, it can be set on the nose with an isolated 60-Hz source and a good ac voltmeter. Use a 1:1 isolation transformer or two filament transformers back-to-back as shown in Fig. 4 and feed the output into the Splattometer. Measure the equivalent input power as the square of the rms voltage divided by 52. If necessary, the series meter resistor can be adjusted so that the pointer exactly indicates the calculated power.

Wattmeter accuracy is also dependent on swr. Remember that the wattmeter is really a peak-reading rf voltmeter which can be calibrated in Watts only because the load is specified as 52 Ohms and $P = E^2/R$. The wattmeter scale will be inaccurate if another load impedance is used; for example, if the load is doubled to 104 Ohms, the indicated power will be twice the actual power. If the transmission line swr isn't 1:1, the problem is harder to solve since the wattmeter readings will vary with the electrical length of the line. The rf voltage on a line having 2:1 swr will vary over a 2 to 1 range depending on line length. The indicated power, if based only on the voltage measurement, would vary over a 4 to 1 range—from about half to twice the actual power! The Splattometer's PEP wattmeter can be calibrated and used as a worthwhile test instrument, but don't forget to consider errors caused by swr. The splatter-detection portion of the instrument will of course be unaffected by swr as long as the wattmeter reading settles out to something between 25 and 700 Watts.

The resistor values at the input rf voltage sampler can be changed to shift the Splattometer operating range if desired. Reducing the 1k resistor to 510 Ohms almost doubles the input voltage necessary to create a specific meter reading, so the instrument will then read from about 100 to 3000 Watts. For low-power operation, the 22k input resistor can be reduced to 9.1k and the resulting range will be approximately 4 to 120 Watts PEP.

During normal SSB operation, the splatter lamp should flash only occasionally, maybe once or twice per sentence. Any more than that is too much and calls for a reduction in microphone gain.

Nobody wants to overdrive his transmitter and cause splatter, but the desire to get maximum output power is a strong one. Until now, the preferred monitoring technique required an oscilloscope. That solution is bulky, expensive, and requires constant attention in a dim room. The Splattometer is a much better alternative: It's inexpensive, unobtrusive, and, unlike the complex oscilloscope display, tells you only what you want to know exactly when you need to know it. You'll certainly find it a worthwhile addition to your equipment if you operate much SSB. Even if you're primarily a CW operator, it might make an excellent Christmas present for that SSB operator down the block! ■

Digital Basics

—part II

In part I of this series, I introduced you to the principal IC logic families and the various different forms of logic gates. Here in part II, we will continue our study of basic digital electronics by investigating *flip-flops*.

Flip-Flops

All of the digital circuits discussed thus far have operated in a "transient" manner. Gates and inverters do not have any *memory*, so once the input condition changes, then the output state that results from those conditions also is likely to change.

A flip-flop (FF) is a circuit that is capable of *storing a single bit* (i.e., a binary digit, either 1 or 0) of digital data; it will remember an input condition and hold the same output after the data has passed. There are various different types of flip-flop circuits, and they all operate on slightly different (even though similar) sets of rules. But one thing that they all have in common is the ability to store a single data bit.

All common forms of flip-flops can be made from various combinations of the basic AND, OR, NAND, NOT, NOR, and XOR gates. The NAND, NOR, and NOT gates are particularly often used to make flip-flops. Except for the two simplest flip-flops presented here in part II, most electronic circuits use IC flip-flops instead of actual IC gates. It is simply too costly to *make* flip-flops from IC gates when the same manufacturers do all of the interconnections for you by offering the various flip-flops pre-made in IC form.

Fig. 1. (a) A reset-set flip-flop (RS FF) can be made from two NAND gates. (b) Symbol for RS flip-flop. (c) The circled inputs for R and S indicate that these inputs are active-LOW. (d) The operation of an RS flip-flop is summarized in this truth table.

Reset-Set (RS) Flip-Flops

One of the simplest forms of flip-flop circuit is the *reset-set*, or *RS*, flip-flop. (Some textbooks, especially those over ten years old, call it a set-reset, or SR, flip-flop.) The RS flip-flop can be made from either two NAND gates or two NOR gates, although note that operation of the two versions is slightly different.

Fig. 1(a) shows the circuit for an RS flip-flop made from a pair of NAND gates, such as the TTL 7400 device (which contains four two-input NAND gate sections).

There are two inputs required on the RS flip-flop, *set* and *reset*. Usually there are also two output terminals, and these are complementary: Q and NOT-Q ($\overline{Q}$). *Complementary* means that one will be LOW if the other is HIGH. For example, when the Q output is HIGH, then the NOT-Q will be LOW. When the Q output is LOW, then the NOT-Q will be HIGH.

The inputs of the NAND version of the RS flip-flop are active-LOW so are sometimes designated $\overline{S}$ (NOT-S) and $\overline{R}$ (NOT-R). Whenever you see an *input* that is designated as a NOT-input, has a bar over its symbol, or that has a circle in the schematic diagram, then we know that it is an active-LOW input terminal. The circuit action of an active-LOW input occurs when the terminal is brought LOW. An example of a schematic that uses the circled inputs is shown in Fig. 1(c), while the normal symbol for the RS flip-flop is shown in Fig. 1(b).

A momentary LOW on the *set* input of the NAND gate RS flip-flop causes the outputs to go to the state where the Q is HIGH and the NOT-Q is LOW. Note that the term *set* usually means Q = HIGH and NOT-Q = LOW, while *reset* indicates just the opposite: Q = LOW and NOT-Q = HIGH. The flip-flop is said to possess *memory* (and, indeed, solid-state computer memory uses arrays of FFs), so the outputs will stay in the set condition unless a *reset* pulse is applied to the *R* input.

The reset function is obtained by momentarily bringing the reset input LOW. This forces the outputs to go to a state in which the Q is LOW and the NOT-Q is HIGH.

The rules for the operation of the NAND-logic RS flip-flop are summarized in the truth table shown in Fig. 1(d). This truth table also lists two additional conditions besides those discussed above. One of these is the condition in which both set and reset inputs are brought LOW simultaneously. This is a *disallowed* state, and the circuit will not know what to do; the output state will be unpredictable.

The other condition is the case where both inputs are simultaneously HIGH. In this condition we find that there is no change in the output state. The RS flip-flop simply remains in the condition present when the inputs were made HIGH.

A NOR-logic version of the RS flip-flop is shown in Fig. 2. This circuit may be constructed from TTL/7402 NOR gates. Like the 7400 device, the 7402 contains four independent two-input gates (in this case, the NOR variety). The circuit in Fig. 2 performs differently from the NAND-logic version of Fig. 1, but there are similarities even though a slightly different set of operating rules prevails.

The rules governing the NOR-logic RS flip-flop are summarized in the truth table of Fig. 2(c), but let's go over them briefly:

1) If *both* inputs are LOW, then there is no change in the output state.

2) If *both* inputs are simultaneously HIGH, then we have a disallowed state and the output condition is unpredictable.

3) If the *set* input is made HIGH momentarily, then the output condition is Q = HIGH and NOT-Q = LOW.

4) If the *reset* input is made HIGH momentarily, then the output condition is Q = LOW and NOT-Q = HIGH.

Note again the principal difference between the two forms of RS flip-flop (examine the truth tables in Figs. 1 and 2 again). The NAND-logic RS flip-flop has *active-LOW* inputs, while the NOR-logic RS flip-flop has *active-HIGH* inputs.

Clocked RS Flip-Flops

We sometimes get into trouble with flip-flops that are too simple. We see, for example, electronic versions of the old *relay-race* problem. In that problem and its modern electronic version with digital circuits, two relays may have slightly different actuation times. If the time difference is such that they operate out of the intended order, then catastrophic results sometimes occur. Many of these problems are solved in the digital electronics world by using *clocked*, or *synchronous*, operation. In the case of the RS flip-flop, we obtain clocked operation by using the *master-slave flip-flop*, also called the *clocked RS flip-flop*.

The purpose of the *clock* (a train of pulses) is to synchronize the changes in the output condition by allowing them to occur only at certain times during, or immediately following, a clock pulse. Most large-scale digital circuits will use synchronous operation in order to keep things straight.

There are two basic forms of clocking used in RS flip-flops: *level-triggered* and *edge-triggered*.

A level-triggered flip-flop is one in which the output state changes in response to conditions on the inputs only when the clock input is either HIGH or LOW (depending upon the type). Some level-triggered circuits require the clock pulse to be LOW for it to be active, while others (the more usual case) require the clock pulse to be HIGH.

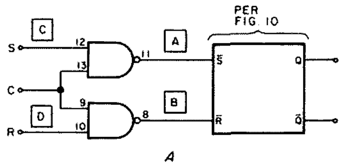
Fig. 2. (a) An RS flip-flop can be made from NOR gates as well as NAND gates. (b) The RS flip-flop built from NOR gates has active-HIGH S and R inputs. (c) A NOR-logic RS flip-flop follows this truth table.



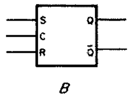


Fig. 3. (a) By adding two NAND gates to a NAND-logic RS flip-flop, a level-triggered clocked RS flip-flop is obtained. (b) Schematic symbol for a level-triggered clocked RS flip-flop.

An edge-triggered flip-flop will allow state changes only during one of the two transitions of the clock pulse. The pulse must be in the process of going from LOW to HIGH, or from HIGH to LOW (again, depending upon type). A positive edge-triggered flip-flop, therefore, will allow output changes to occur only on the positive-going transition (LOW to HIGH) of the clock pulse. A negative edge-triggered flip-flop allows output transitions only on the negative-going (HIGH to LOW) transition of the clock pulse.

It is important to remember the difference between these two types of triggering, so let's reiterate: *Level triggering* means that changes can take place only during the time when the clock pulse is active, i.e., either HIGH (positive level-triggered) or LOW (negative level-triggered); *edge triggering* means that output changes can take place only during the transition period of the clock pulse. A positive edge-triggered FF changes only on the LOW to HIGH transition, while a negative edge-triggered FF wants to see the negative-going, or HIGH to LOW, transition.

An example of a simple level-triggered clocked RS flip-flop is shown in Fig. 3. The main flip-flop is the same as the circuit in Fig. 1, so it is shown here in block form for the sake of simplicity. The *S* and *R* inputs are controlled by a pair of NAND gates. When the clock pulse is LOW, then both inputs of the RS flip-flop section (i.e., points A and B) see a HIGH, so no change can take place.

But, when the clock input goes HIGH, the levels at points A and B (i.e., the *S* and *R* inputs of the FF section) are then controlled by the other inputs of the NAND gates. These inputs are used as the *S* and *R* inputs of the clocked FF. If you doubt this, then review the operation of the NAND gates.

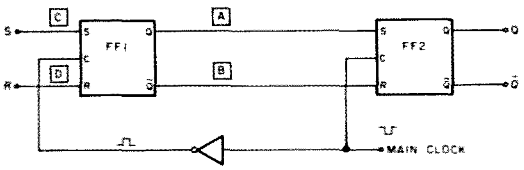

Fig. 4. Two RS flip-flops in a back-to-front configuration constitute a master-slave (M-S) flip-flop. This circuit allows only one output state change per clock pulse.

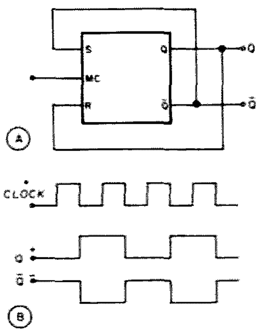

Fig. 5. (a) A type-T, or toggle, flip-flop is obtained by adding feedback connections to a master-slave flip-flop. This circuit acts as a binary divider. (b) For a toggle flip-flop, a negative-going transition of the clock results in a change of the output (Q) status.

D

Fig. 6. (a) Two AND gates and a type-T flip-flop combine to form a J-K flip-flop. (b) Several designations (MC, T, or Cp) are used to indicate the clock input for a J-K flip-flop. (c) When both the preset and preclear inputs are HIGH, a J-K flip-flop is in the clocked mode. The output depends on the status of the J and K inputs. (d) Direct control of the J-K flip-flop is accomplished by using the preset and preclear inputs.

Master-Slave Flip-Flops

The use of clocking helps a great deal in taming the RS flip-flop, but several problems, again electronic versions of the old relay-race problem, still occur. Most of these are solved by using a slightly different approach—the so-called *master-slave flip-flop*. An example of the master-slave FF is shown in Fig. 4. This circuit allows only one output state change per clock pulse (the clocked RS FF allows continuous output state changes as long as the clock input is active).

The M-S flip-flop of Fig. 4 uses the clocked RS flip-flops of the previous example connected in cascade. The inverter shown allows us to drive the clock inputs of the two clocked RS FFs out of phase with each other.

Recall that the clocked RS flip-flop can change its output state only when the clock input is HIGH, and then only in response to conditions on the R and S inputs. In the M-S FF, the main clock is kept HIGH, so FF2 is active and FF1 is inactive.

When a clock pulse is applied (in this case a negative transition), FF1 will become active, and FF2 becomes inactive. Note that the effect of the inverter is to make the clock input of FF1 HIGH at this time. Any commands placed on the *S* and *R* inputs will cause changes in the outputs of FF1 (i.e., points A and B in Fig. 4).

But, because FF2 is inactive at this time (its clock input is LOW), changes at A and B are not yet reflected at the Q and NOT-Q outputs of FF2. But, once the master clock goes HIGH again, the clock input of FF2 goes HIGH again, so the changes that took place on A and B can be transferred to action at the Q and NOT-Q outputs.

The synchronization occurs by keeping FF2 inactive when the input stage (FF1) is being set up, and then rendering FF1 inactive (forbidding further *S* and *R* input changes from affecting the output), while transferring the data to FF2. This part of the sequence is called a *load-transfer operation*.

Additional Types of Flip-Flops

Thus far we have considered two versions of the RS flip-flop (NAND logic and NOR logic) and two flip-flops that are derivatives of the RS circuits, the clocked RS flip-flop and the master-slave flip-flop. In the sections to follow, we will consider some more complex types of flip-flop: *type-T* FF, *J-K* FF, and the *type-D* FF.

Type-T Flip-Flops

The type-T flip-flop (also called the *toggle FF*) is shown in Fig. 5. This FF circuit can be constructed by providing feedback connections (as shown) around an ordinary master-slave flip-flop. Recall that the M-S FF was constructed from a pair of RS FFs and an inverter stage. Note that the Q output is fed back to the reset input and the NOT-Q output is fed back to the set input.

The type-T flip-flop functions as a binary divider; that is, the output signal has a frequency that is one half (i.e., divided by 2) of the input signal. The timing diagram for this circuit is shown in Fig. 5(b). Note that the Q output changes state only on negative-going transitions of the clock pulse. At the first negative transition, the Q output will snap HIGH and remain HIGH until the clock input sees *another* negative transition. This condition occurs at pulse number 2, at which time the Q output goes LOW again. We have, therefore, binary division of the input frequency: One output pulse is produced for each two input pulses.

There sometimes are found differences in terminal designations from one text or spec sheet to another. In Fig. 5(a), for example, we have labeled the clock input *MC* for main clock. But it is likely that you also will see T for toggle, or C_p for clock.

J-K Flip-Flops

One of the most useful and perhaps most common forms of clocked FFs is the J-K flip-flop. There are several advantages to the typical J-K flip-flop. (a) There are no invalid or disallowed states in the clocked mode. (b) It can cause the outputs to complement. And (c), it can provide non-clocked operation (in some IC versions).

Fig. 6 shows one of several popular ways to represent the J-K FF. In this case, we see that it is a type-T FF with feedback to the set and reset inputs controlled by a pair of two-input AND gates. One input from each gate accepts the feedback lines, while the remaining inputs of the gates are used to form the *J* and *K* inputs of the FF, respectively.

Fig. 6(b) shows the circuit symbol for a J-K flip-flop.

Not all versions of the J-K will have the direct-mode inputs (preset and clear). These inputs do, however, make it a more useful device. The *preset* input may also be called a *direct-set* input, and the *preclear* input called a *direct-clear* input.

Direct mode operation. The operation of the J-K flip-flop in the direct mode is very simple, and it is independent of conditions applied to the J and K inputs. The direct mode is controlled only by conditions on the *preset* and *preclear* input terminals, and the rules are summarized in Fig. 6(d).

The direct mode inputs are active when LOW, so the only disallowed state occurs when both are simultaneously LOW.

If the preset input is LOW and the preclear input is HIGH, then the outputs immediately go to a condition where Q is HIGH and NOT-Q is LOW.

If the preclear input is made LOW and the preset input is HIGH, then the outputs go to a state where Q is LOW and NOT-Q is HIGH.

It is a general rule, when dealing with flip-flops of any type, that set or preset operations make the Q output HIGH and the NOT-Q output LOW, while clear and reset operations work in just the opposite manner (i.e., Q LOW and NOT-Q HIGH).

If both preset and preclear inputs are made HIGH, then the flip-flop is ready for normal clocked operation.

Clocked operation. Whenever the preset and preclear inputs (where used) are simultaneously HIGH, the J-K will operate in the clocked mode. The rules for clocked operation are summarized in Fig. 6(c).

Like the type-T FF, the J-K FF (in the clocked mode) responds on the negative-going transition of the clock pulse. No output changes will occur regardless of changes at the *J* and *K* inputs, until one of these negative-going clock pulse transitions is seen. The outputs will then respond according to the J-K input conditions. The rules for clocked operation are as follows:

1). If both J and K are LOW, then the FF is inert and does nothing. No changes will occur in the outputs.

2) If J is LOW and K is HIGH, then the clocking will make Q LOW and NOT-Q HIGH.

3) If J is HIGH and K is LOW, then the clock pulse transition makes Q HIGH and NOT-Q LOW.

4) If both J and K are HIGH, then the J-K FF behaves much like a type-T FF; clocking complements the outputs. This means that negative-going clock-pulse transitions force the outputs to go to the opposite state. The output waveform of the J-K flip-flop is then identical to the output waveform of the type-T flip-flop given in Fig. 5.

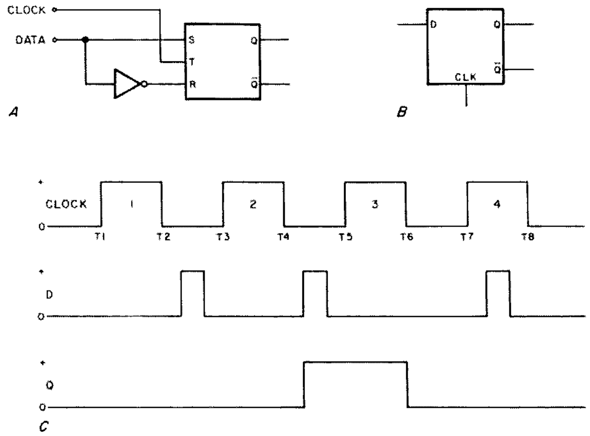

Fig. 7. (a) The type-D flip-flop is a derivation of the RS FF. (b) Symbol for a type-D flip-flop. (c) Data appearing on the D input is transferred to the Q output only when the clock line is HIGH.

Type-D Flip-Flop

The type-D or *latch* flip-flop is shown in Fig. 7. The equivalent circuit is shown in Fig. 7(a), while the usual schematic symbol is shown in Fig. 7(b).

The equivalent circuit consists of a clocked RS FF in which the set and reset inputs are fed by the same signal but are 180 degrees out of phase with each other (i.e., complementary inputs). An inverter between the *S* and *R* lines accomplishes this neat trick.

The common line to the reset-set-inverter is called the *data* or *D* input instead of clock. This input is usually labeled D on most schematics.

The rule for operation of the type-D FF is very simple: Data appearing on the D input will be transferred to the Q output only when the *clock* line is HIGH.

1) If the clock line is HIGH, then the output will *follow* changes in the input signal (i.e., changes on the *D* input). When the D line goes HIGH, then the output will go HIGH. Similarly, when the D line goes LOW, then the outputs follow by also going LOW.

2) If the clock line is LOW, then the output will retain the last data that existed on the D input at the instant the clock line dropped LOW.

These rules can also be seen in the timing diagram of Fig. 7(c). Read the description below, keeping in mind the two rules just given.

a) When the first clock pulse arrives (T1-T2), the D input is LOW, so the Q output also will be LOW.

b) During the interval T2-T3, the D input goes HIGH, but since no clock pulse is present, it cannot affect the output conditions.

c) At the beginning of interval T3-T4, clock pulse number 2 is HIGH, but the D input is LOW. The output, therefore, must remain LOW.

d)Approximately midway through clock pulse 2, however, the D input goes HIGH, forcing the Q output to also go HIGH.

e) The Q output stays HIGH even after clock pulse 2 goes LOW.

f) At the onset of clock pulse number 3, the D input is LOW, so the Q output drops LOW also.

g) The pulse on the D input during the interval T6-T7 cannot affect the Q output because the clock is LOW.

The so-called *data latch* device is a special case of the type-D flip-flop. This device is used in digital-readout circuits (e.g., in frequency counters) to hold current data until the new data has been updated and is ready for display. This gives the illusion that the data is updated instantaneously. In most cases, the clock input is called a *strobe* input. Data at the D input will be transferred to the Q output only when the strobe line is HIGH. The idea is to bring the strobe line momentarily HIGH when the data at the input is valid, and then let the strobe line go LOW again until the next newest data is ready.

And Now. . .

The third and final part of this series, to be published next, will allow you to wade into digital electronics up past your knees. The topics will be the most common multivibrator and counter circuits.■

Dissertation Upon Roast Pig

—the ultimate in surplus?

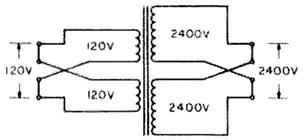

Fig. 1. 120-to-2400-volt connection.

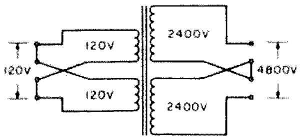

Fig. 2. 120-to-4800-volt connection.

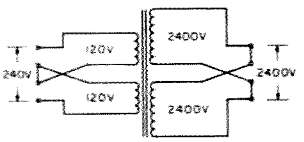

Fig. 3. 240-to-2400-volt connection.

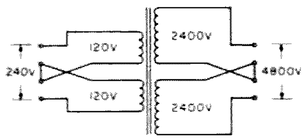

Fig. 4. 240-to-4800-volt connection.

This article is called "Dissertation Upon Roast Pig," with apologies to Charles Lamb, author of the essay with the same title. The poem was learned in high school literature class back in 1933, one year before I obtained my first amateur radio license (W9RTS). As you may remember, this was a comical poem which supposedly gave the origin of the succulent dish, roast pig. With regard to ham radio, roast pig refers to a much used, or roasted, transformer commonly known in amateur circles as "the pole pig." The dissertation is intended to bring a tear of joy to the eye of the old-timer, to acquaint the newcomer with the meaning of the term "pole pig," and to provide some technical know-how with regard to its use. Maybe some humor will creep in as well. First of all, what is a pole pig? Photo A shows a group of four. It is a distribution transformer which has for all intents and purposes served its useful

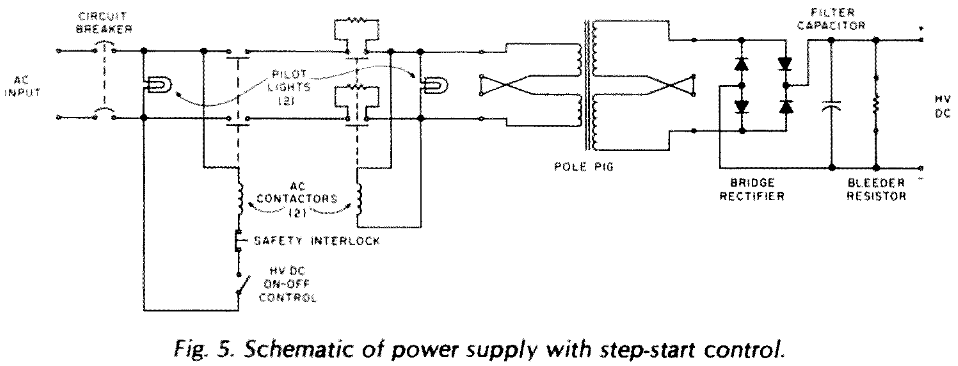

Fig. 5. Schematic of power supply with step-start control.

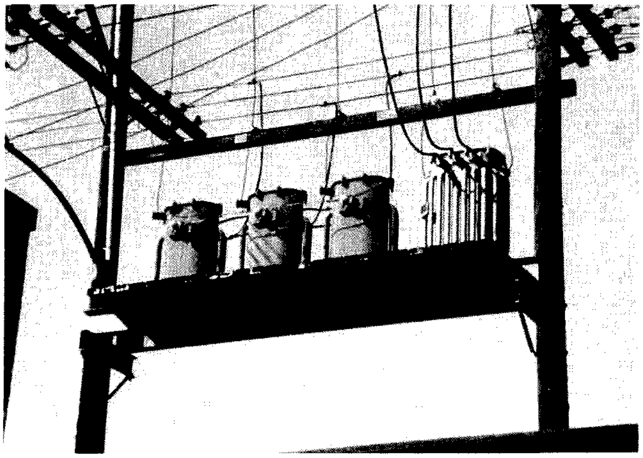

Photo A. A group of four pole pigs.

Photo B. Tools needed to procure a pole pig.

life and been relegated to the scrap heap. It has been used, or "roasted," for a long time by the electric power company for its primary purpose, that is, as a transformer which reduces the high voltage, as distributed, down to 120 volts each side of neutral for domestic use.

The term "pole" is taken from the fact that these transformers are usually mounted on a pole. The term "pig" is derived from the fact that, as amateurs are able to get them, they are unusually dirty and messy. They are completely saturated with transformer oil and have seen considerable use in power company service. They come in various sizes: 1, 3, 5, 25 kVA and larger. You will seldom see them larger than 50 or 100 kVA in your neighborhood. Of course, any transformer larger than 5 kVA is of no interest to us anyway.

Hams of long ago, and some to this day, used pole pigs to serve as the plate transformers in power supplies for their transmitters. The main reason that hams used them was the fact that they were cheap. About ten to fifteen years ago, they were available at electric company salvage yards for about $2.50 per kVA. They were, of course, used, but by judicious selection you could obtain a nice transformer for your plate supply.

In order to get a pole pig, supply yourself with a set of tools such as those shown in Photo B. Then go down to the electric power company salvage yard, identify yourself, and start off. Incidentally, I am told it is not so easy to do this as in times past. Well, anyway, meander around the yard, searching for the transformer of your choice. Photo C is typical of what you might expect to see. When you find one, give it the nose test. Smell it to make sure it is not burned out. A clever nose will find it easy to determine when a transformer is burned out. After making a choice, ask the yard attendant to drain the oil. Sometimes they are already drained, because the power company cleans and reuses the oil. After draining the oil, take hacksaw and cutting pliers and cut the leads going to the external terminals of the case. Following this, take the hammer and, with an old screwdriver serving as a chisel, remove the wooden wedges holding the transformer in the case. Then remove it from the case. If you are lucky, the yard attendant will help you do this, using a forklift, and then deposit the transformer into your car trunk or trailer. Incidentally, have plenty of rags and paper upon which to place it, since these transformers keep on weeping oil for months after acquisition. After you get it home, don't do anything to it for about six months except store it in a corner on a stack of newspapers to absorb the oil. This oil was used to cool and insulate these transformers in normal service, but is not required for intermittent amateur service.

Photo C. Possible candidates.

Now, having obtained a pole pig, and after allowing most of the oil to drain, let's see what it requires to put one into service. The next two photos show what was done with a 5-kVA, 4800-volt-to-240-volt unit.

Photo D is a front view with the high-voltage terminals toward you. Note that they are encased in red fiber tubing. These tubes have been cut down from their original length, since these terminals would stick up too high otherwise. Photo E shows the 240-volt terminals toward you. Note the larger solder lugs and also that the two center terminals are connected together, on both high and low voltage windings. More about the connections later. You may observe that this transformer is quite neat and has risen above the looks of the average pole pig. But then, let's use it.

Photo F shows a completed power supply assembled into a 22-inch by 30-inch by 40-inch roll-

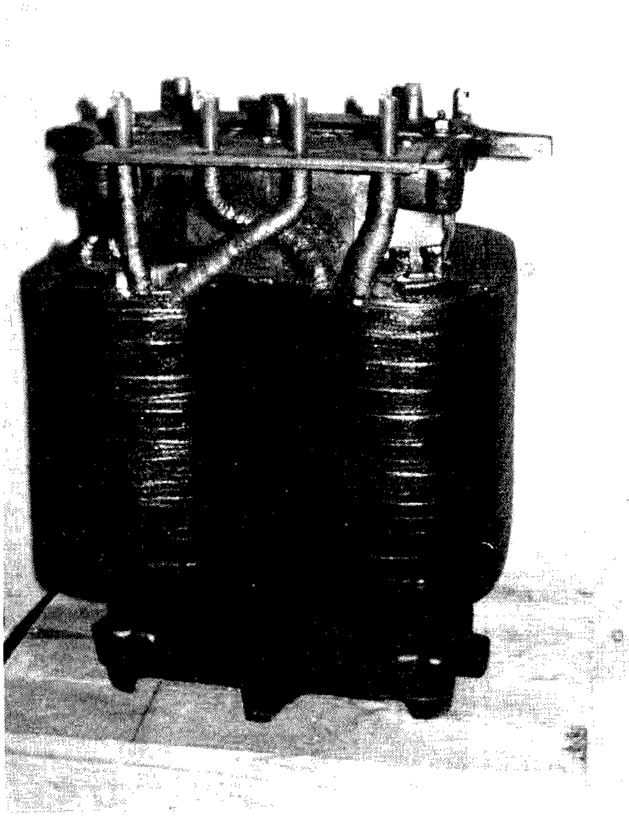

Photo D. Front view showing high-voltage terminals.

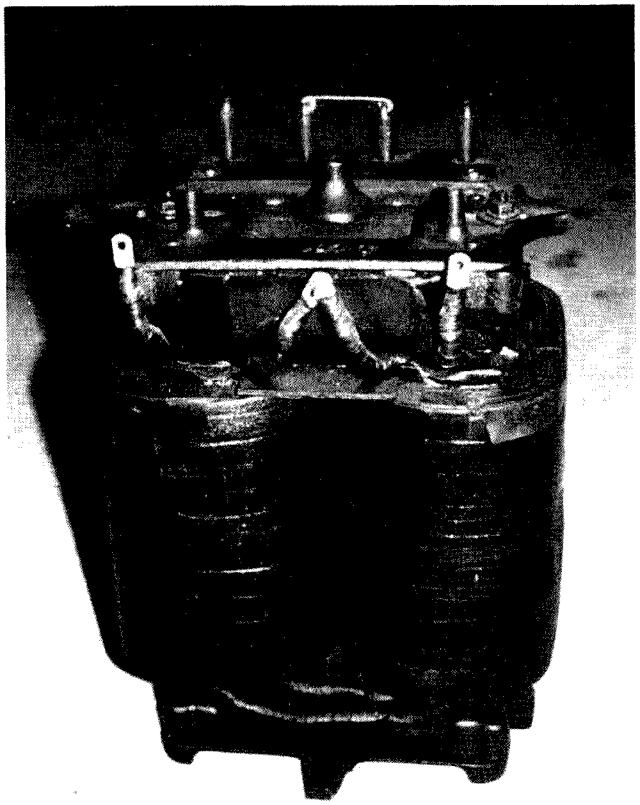

Photo E. View showing 240-volt terminals.

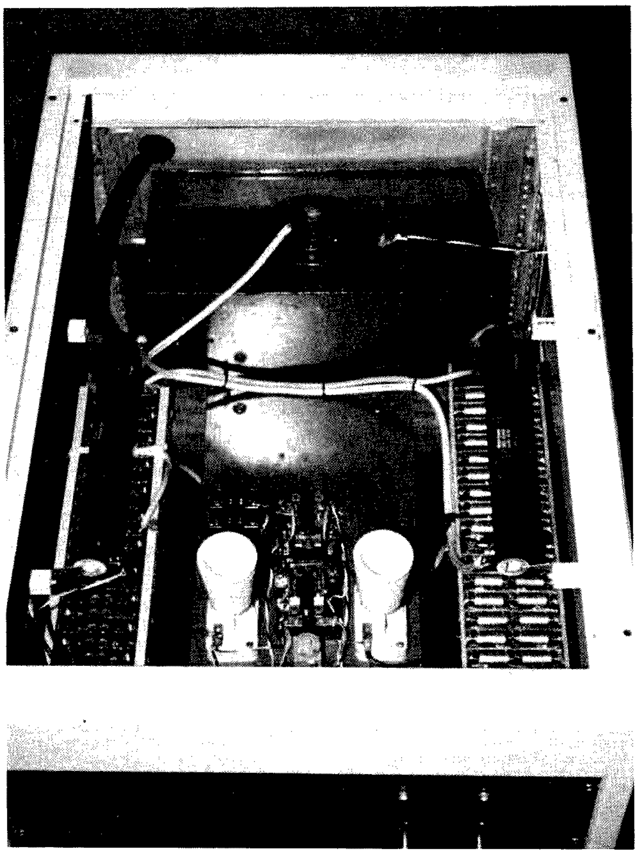

Photo F. Completed power supply.

around cabinet. A 0-to-240-volt Variac is used for controlling the dc output voltage from 0 to 5000 volts dc. The 5-kVA transformer can supply 1.5 Amperes with good regulation. Note the orange-colored device. This is a 10,000-volt-dc, 180-uF capacitor. Also, if you look closely on each side near the top, you can see the solid-state diode stacks and, immediately above them, the bleeder resistors. Note also the cone heaters and two contactors which will be explained later. This supply was designed to furnish power to a number of final amplifiers for contest work. The 180-uF capacitor and the 5-kVA pole pig are well able to supply the concurrent demands of several kilowatt amplifiers.

Photo G shows a 3-kVA transformer that represents an ideal size for a single high-power amplifier. It is in use in an amplifier using a 4-1000A in grounded grid. This particular one was dipped in black transformer insulating material, and when oven dried became a thing of real beauty. Yours truly is shown lifting it in Photo H.

Well, how do you connect a pole pig for use? The diagrams show the various input and output voltage connections. Note how the primary and secondary coils are strapped. All transformers of this type utilize two primary and two secondary windings for purposes of voltage changing. This first application shows parallel use of primary and secondary windings. Next, by connecting the secondary in series (Fig. 2), we obtain a 120-to-4800-volt transformer. The 4800-volt winding can be used either in a bridge connection or center-tapped. For a kilowatt amplifier, operating the power supply on 120-volt input is not recommended, since voltage drop

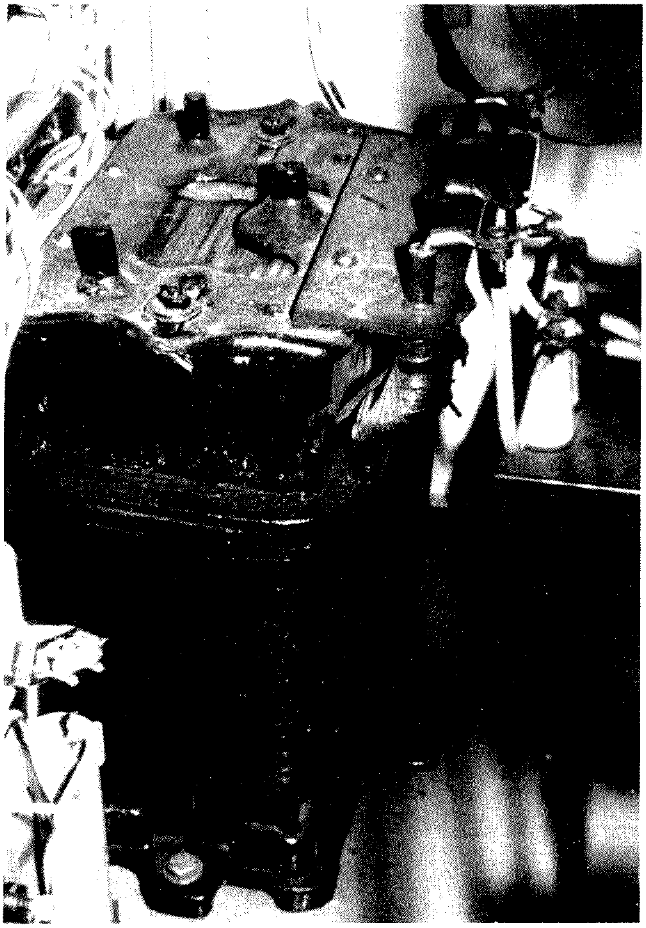

Photo G. A 3-kVA transformer, ideal size for a single high power amplifier.

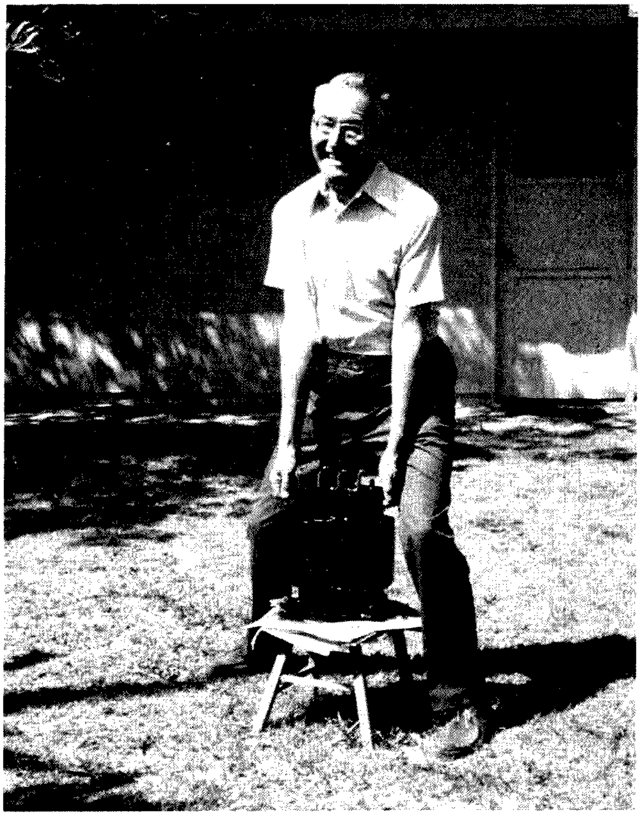

Photo H. The author lifting the transformer of Photo G.

on the primary input lines will be excessive, leading to poor regulation and efficiency.

Fig. 3 shows the connection for 240-volt input and 2400-volt output. Best use for this would be in a bridge circuit furnishing 2500 volts dc.

Fig. 4 shows the most widely used circuit. The 240-volt input is boosted to 4800 volts, which will provide 5000 volts dc in the bridge connection or 2500 volts dc in the center-tap full-wave connection.

For diode and filter protection, it is best to use a step-start circuit as in Fig. 5. This is where we use the cone heaters and the contactors. When the start switch is turned on, the first contactor operates, applying voltage to the transformer through the cone heaters acting as resistors. These limit the inrush current to a safe value for the diodes. After the filter has charged to a certain level, the voltage drop across the resistor decreases to a point permitting the second contactor to be energized. This contactor shorts out the resistors, thus permitting full voltage to be applied to the transformer. I heartily recommend the step-start arrangement. I have used it for years on supplies using 872s and solid-state diodes and never have had a failure due to excessive peak currents.

Finally, it is realized that not too much home-brewing is going on. But it is hoped that at least it may be interesting to many to become acquainted with the formerly much used pole pig.■

Got an Apple? Want RTTY?

—try this hard-core interface

After spending many years using various Teletype® machines and, most recently, a less-than-adequate video RTTY set-up, I finally decided to use my Apple II computer for this mode. I have owned my Apple for three years and have had the Chuck Galfo (WB4JMD) RTTY/CW software for two years.[1] The only thing lacking was the interface circuitry to connect the Apple to my ST-6 demodulator and HF/VHF radios. Galfo provides a sample interface in his software documentation, and Fig. 1 shows the block diagram of my final interface.

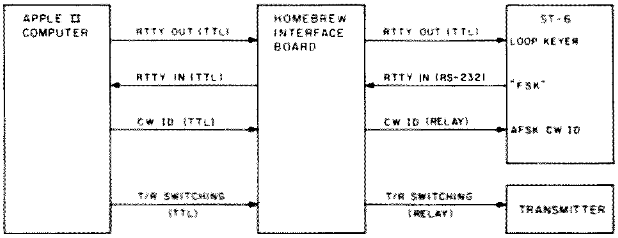

Fig. 1. Block diagram.

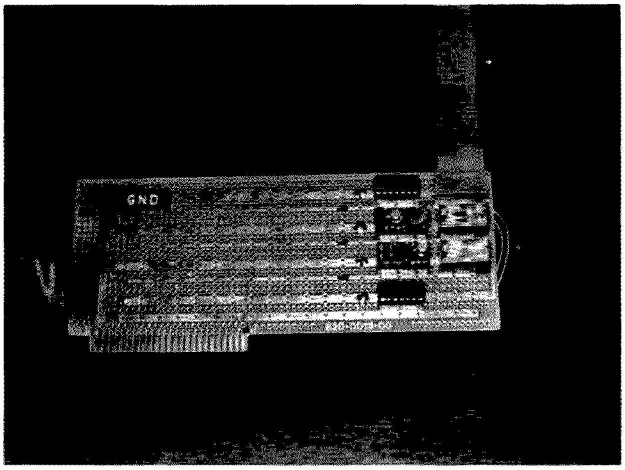

Fig. 2. The interface on an Apple prototyping board.

Interconnections to the Apple are made through the game paddle I/O port. The interface was built on an Apple prototyping board (Fig. 2) using wire-wrap; it is connected to the game paddle port through a 16-wire ribbon cable and to the outside world through a 12-pin molex® connector. The few transistors, resistors, and capacitors are mounted on two dip headers to simplify construction.

Fig. 3 is the schematic of my interface. TTL-level teletype transit pulses are available at pin 15 (AN0) of the game-paddle, 16-pin IC socket. To correctly key the loop keyer in the ST-6, these pulses must be inverted. This is done by one NAND gate of the 7404 IC. These pulses key the 2N706 transistor which in turn keys the ST-6 loop and the XTK-100 (or AK-1 depending on the age of your ST-6) AFSK oscillator for transmission of the audio tones. The 2N706 is mounted on a small PC board connected piggyback to circuit board #3 (active low-pass filter/slicer/keyer) in the ST-6. The interconnection point is indicated in Fig. 4.[2]

Received RTTY pulses are a little more difficult. The ST-6 provides both a 60-mA loop and "RS-232" (±20 V dc) pulses (FSK pin on the ST-6 rear panel). I chose to work with the FSK output, normally used to drive the FSK circuit in a transmitter, converting this signal to TTL logic levels required by the Apple using an MC1489 converter.[3] The TTL pulses are then routed to pin 2 (SW0) of the paddle port. The 6-pin AFSK-KEY/FSK-KEY molex connector on the rear panel of the ST-6 becomes the Apple's connection point. Since I use AFSK I have no need for the "FSK" circuit keying pulses; I removed the molex pin and replaced it with the line

running to the 2N706 keying transistor.

CW ID is available at pin 13 (AN2) and keys the simple relay circuit. Transmit/Receive switching signals are outputted to pin 14 (AN1) and key an identical relay circuit as the CW ID function. T/R status is indicated by two LEDs as shown. Rather than modifying the Apple case, I mounted these LEDs in a small box and attached it to the Apple using a Velcro® strip (Fig. 5).

Operating voltages are available from the Apple power supply and appear on the prototyping board. Plus 12 V dc to operate the relays is found on pin #50 of the prototyping board. Galfo recommends that all lines entering and exiting the computer be bypassed to ground with small (200-μF) capacitors. The prototyping board documentation recommends that all voltages on the board should be decoupled with a 0.1-μF capacitor to ground near the I/O connector board pin. Do NOT use high-value electrolytic decoupling capacitors as they can cause improper operation of the Apple power supply. I highly recommend these bypasses, although I have run a kW on RTTY without them and have experienced no glitches.

A few words of caution at this point are appropriate. First, as you can see from Fig. 6, the interface board is mounted in slot #7 of the Apple and is next to my disk controller board. Since I used wire-wrapping, the component side of the interface board faces the component side of all other peripheral boards. I placed all of the wire-wrap sockets at the end closest to the keyboard. If I were to reproduce the board again, I would move the 16-pin connector going to the ST-6 to the same end as the components to preclude any interference with the disk controller board. Second, be sure that you *always* turn the power off to the computer before inserting or pulling out the interface or any other board! All cables connecting the Apple to the outside world should be shielded. I used microphone cable (two conductors plus a shield) for those lines and tied them together using small tie-wraps to form a neat cable.

Galfo's software is outstanding. It allows you to transmit and receive Baudot and ASCII at all the popular speeds and, in fact, will operate at any baud rate between 32 and 300 baud. Split screen, automatic CW ID, prepared messages, and automatic T/R switching make operating a real pleasure. When I purchased the program it came on cassette tape, but it can easily be transferred to disk and, as careful inspection of the basic program listing shows, the disk commands to BLOAD the machine language routines are already present.

I turned my RTTY diskette into a turnkey system by making the Integer BASIC program the "HELLO" program. So all I have to do is pop the diskette into the disk drive, turn on the Apple, and the system will automatically come up with the five prompts required to initiate RTTY operation. One last caution: When the computer is on but the RTTY software is not in use, the T/R line is held in the transmit condition. Therefore, if you have your transmitter turned on it will be keyed. To fix this I simply installed a switch in the T/R line to disable this function when both the computer and my transmitter are in

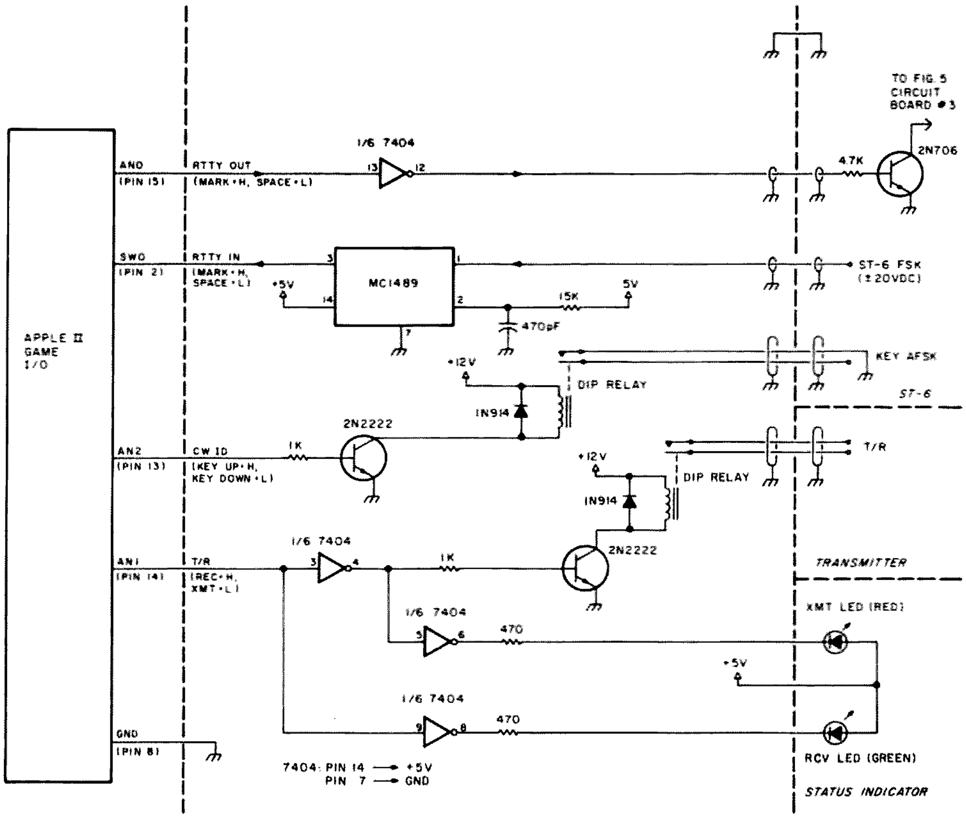

Fig. 3. Interface board schematic.

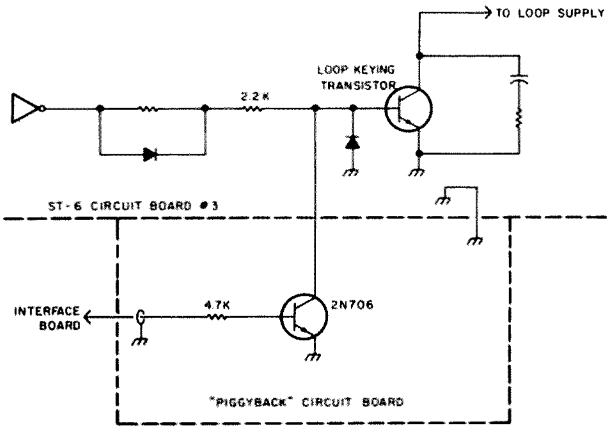

Fig. 4. ST-6 transmit keying point.

WHEN YOU NEED JUST A LITTLE MORE AUDIO

The FASTRAK® model 2003 audio amplifier module produces 250 mW of low THD audio. This transformerless design has a low parts count and does not require a heatsink.

The model 2003 features a dc-operated volume control. Output level is selected by changing a dc voltage with an on-board pot, remote pot or micro-computer D/A interface.

- Low-Z, ac-coupled output drives speaker or headphones.
- Dc-type volume control assures hum-free operation without using shielded cable to the volume control.
- No interstage transformers or heatsinks.
- Compatible with other FASTRAK® modules, such as the model 2002 sound synthesizer.
- One evening assembly using 3.6 by 1.0 inch pc board and instructions supplied.
- Price: $9.45

Price includes: glass-epoxy, etched, plated, drilled pc board; instruction manual; postage in U.S.A. (Ohio residents add 5% sales tax).

Send $1.00 for illustrated FASTRAK® product catalog and refund coupon.

use but not in the RTTY mode.

Computer RFI is a problem that has received a lot of attention lately. I am happy to report that the Apple (at least *my* Apple) does not affect my HF or VHF rigs at all. It does manage to tear up TV reception in the shack though!

Galfo's software package will also transmit and receive CW, but I have yet to build that interface. There also is a new, disk-based version of this package. It provides logging and the ability to send and receive BASIC programs, but I have not purchased it as yet.

The interface can be built for less than $50 (including the $24 for the prototyping board) and most of the parts were bought at Radio Shack. The software is available for $20-$30 depending on which version, cassette or disk, you want.

Considering the price of commercially-available interfaces, this is a powerful yet simple (and cheap!) method to put your Apple to use in your RTTY station. The interface should be adaptable to just about any other TU with minor modifications. I would be happy to answer any questions and will welcome any comments or suggestions. Please enclose an SASE with all correspondence. See you on the green screen. ■

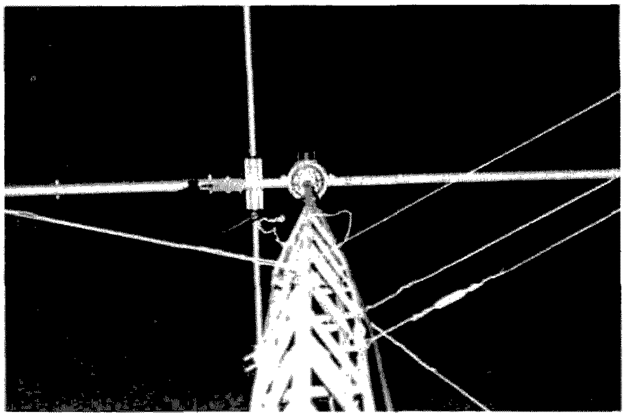
The Pleasures and Perils of Crankup Towers

—don't lose your head!

A tower is well known as one of the most beneficial station accessories an amateur may own. Standing as an outdoor monument to our superb world of long-distance communications and international friendships, the amateur's tower supports that final and most important link in his setup—the antenna. The height of such towers is usually a compromise influenced by cost, self-serviceability, and neighborhood acceptance.



A triband beam on the crank-up tower nestles in its fully-retracted position awaiting the impact of an approaching late-night storm. The photo was taken at midnight with flash and 400 ASA film.

Recently, the somewhat limited in height but highly versatile crank-up tower has gained renewed interest in amateur circles. This article will present some vital information concerning crank-up towers so that the reader may be made aware of their favorable and unfavorable aspects. In some situations, this information may provide new light for cliff-dwelling amateurs. In other situations, this information may help prevent serious personal injury to unsuspecting owners of crank-up towers. This is not to imply that crank-up towers are excessively dangerous, but rather to remind that there are right and wrong ways for using these antenna supports.

The Pleasures

Zoning laws and neighborhood restrictions are affecting an increasing number of radio amateurs each day. Unfortunately, it's becoming more and more difficult for amateurs to erect a simple triband beam on a reasonably-sized tower (40 to 50 feet). Quite often, this problem is solved with the aid of a crank-up tower mounted out of view behind a house. The antenna may thus be raised above roof level only during periods of actual on-the-air use. Additionally, if this activity is confined to night hours, darkness can cloak the raised array.

Many amateurs are not able to climb towering heights (no pun intended!) and must forego antenna tuning or repairs until a

suitable "antenna party" can be organized. Crank-up towers, however, may be erected initially against the side of one's house, and future changes or repairs may be made by the amateur while sitting or standing on his roof. If the tower is secured to the house, it may be used as a ladder to access the roof. Warning: Never climb a crank-up tower that isn't securely lowered to its resting position. An inside section could slip and break an arm, leg, or foot.

Adequate guying is another sensitive area of tower installations. Many times, upper level guys require more real estate than an amateur can provide. Limiting reasons range from guy wires obtrusively crossing established boundaries to unwarranted TVI complaints from neighbors. Two-section crank-up towers which are raised to full height only during use need to be guyed only at roof level (near the top of the lower section).

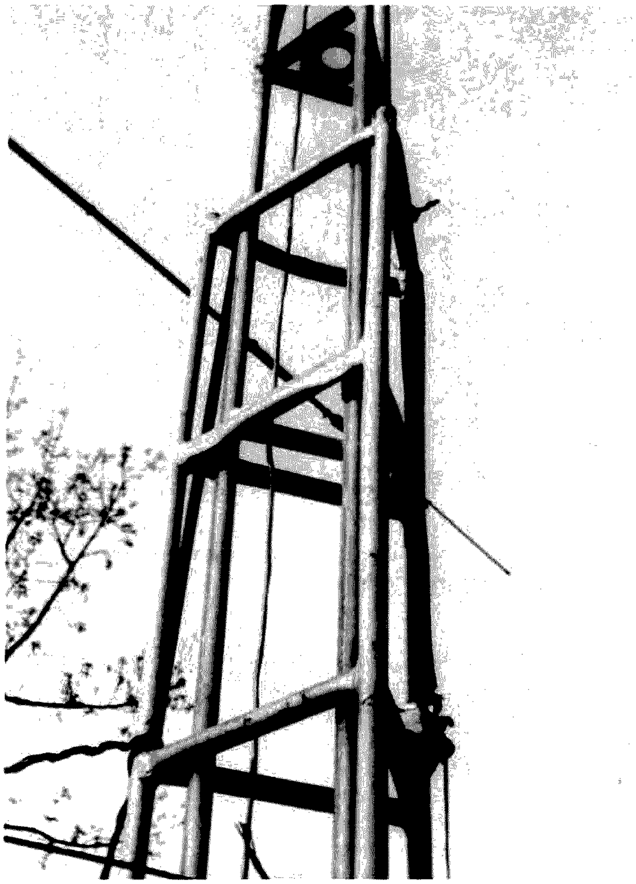
The wind-load rating of a lowered crank-up tower is much greater than a comparable full-height tower. Here in Alabama, for example, our crank-up tower and triband beam have "rode through" many extreme storms and tornado side-effects with no damage while smaller towers and antennas have been totally destroyed. (But I'd better not brag!)

Crank-up towers maintain a relatively high resale value; consequently, many amateurs secure these towers to their house and guy them at one level. The bottom section is then placed in one or two feet of dirt. This method permits the tower to change locations with the amateur, rather than being left behind in a massive pillar of concrete.

The mental (and sometimes physical!) security obtained by lowering your towering giant of an antenna to mere roof level as a violent storm approaches is sheer bliss. I speak from experience. Have you ever run out during a hailstorm and started replacing snapping guy wires as a tornado passes within a few miles of your home? Have you ever wrapped the aforementioned guy wires around yourself and held onto a swaying tree only to see your three-element quad become a rotary loop? Yes, crank-up towers are a blessing for the less-than-stout-hearted amateur!

How Crank-Up Towers Work

A crank-up tower consists of one or more concentric sections which move vertically on track guides within lower sections. An aircraft-type flexible cable is affixed to the smaller inside section's bottom rung, passed through a pulley near the top of the larger outside section, and fed down the tower's outer side to a winch mounted a few feet above the outside section's bottom end. As the pulley cable is reeled onto the winch, the tower's inside section is raised up toward the outer section's top-mounted pulley. A safety latch, or ratchet, is included near the outer section's top to prevent accidental down-plummeting should the operator let go of the winch crank. The latch is secured with a spring, and a control line extends downward so that it can be operated from the cranking position.



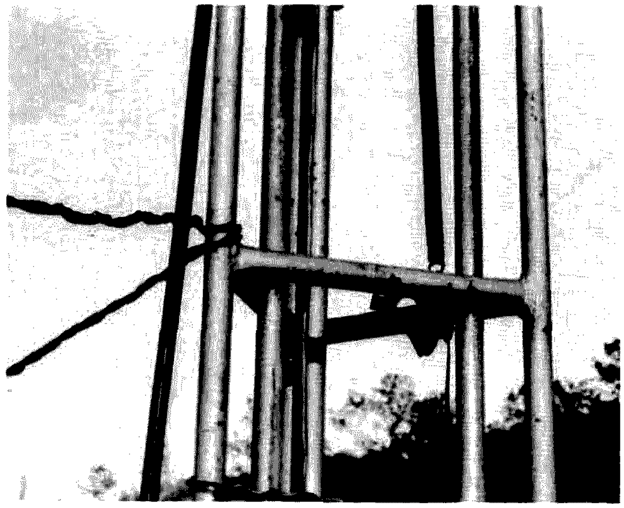
A safety-latch system used with many crank-up towers is shown here. A spring, fastened to the top rung of the lower (outside) tower section (see tie-wire projecting out to the right), extends down to and holds firm the "C" latch, here engaged with the third rung down of the outer section. The latch can be disengaged by the safety line, here extending downward from the latch, and when the inner section is cranked up about two inches, it then can be lowered past the outer rungs. Should the operator let go of crank and safety line, the spring will slam the safety latch back in position to engage the next rung down.

The Perils

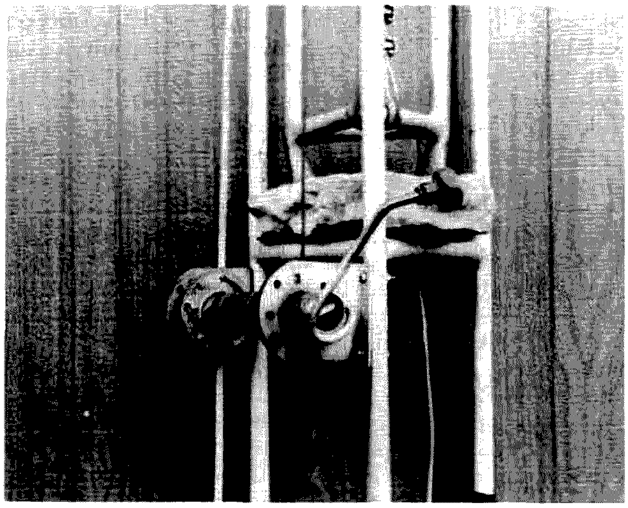
An improperly operated or unmaintained crank-up tower may, in some respects, resemble a modern guillotine. If a small, inside tower section which is weighted at its top with a triband beam uncontrollably falls straight down, it easily can sever a hand, arm, or foot which might be in its path of travel. Never rely solely on safety latches or catches for protection, and never allow any part of your body to get into a raised tower without foolproof safety backups such as concrete chocks between sections.

Assume, for example, a wasp surprise-attacks you as you're cranking a tower. If you inadvertently let go of the winch, it may rapidly unwind and crack your wrist or rib in a split-second's time. If this same tower isn't perfectly plumb, rungs on the inner section can jump the safety latches and the guillotine effect is created. Assuming you manage to get clear of the plummeting tower, the sudden stop at the bottom (fully retracted position) can snap beam elements or boom supports.

These perils can be reduced to a minimum by periodically ensuring that all safety latches operate properly, that their springs maintain ample latching pressure, *and* that additional fall-limiting chocks on raised crank-up towers are used. Ratchet teeth on the



Another view of the safety-latch system. The "C" latch is held in the rung by the spring. The safety line can be seen extending down from the latch.



This is the working position of the crank-up tower. Note the use of the solid chock across the rungs, preventing the inner section from descending further. Visualize this chock being replaced with a hand or arm and a cable breaking. Obviously, safety should be a priority consideration for crank-up tower owners.

cranking winch should also be maintained in sharp, toothy condition to prevent winch-handle cartwheeling. Inspect all latches and springs periodically to ensure that rust and/or corrosion isn't hampering their operation.

As an additional safety measure, an amateur might place a concrete or steel chock above the "working position" (winch location) to prevent personal injury should a cable snap during cranking. Also, an auto's front wheel spring can be placed inside the larger tower section at ground level to cushion any accidental inside section drops.

Occasionally, an amateur may raise his crank-up tower slightly higher than suggested by the manufacturer. If the tower is leaning 3 or 5 degrees from perfect plumb, the upper section can tilt and become stuck at this height. Hmmm—a cocked guillotine!

First, never raise an unplumb crank-up tower to a point where over one-third of the moving section is above its larger lower section. If, however, such misfortune does occur, the amateur must cautiously free the off-center stuck section. Double-chock the tower's upper and lower sections to limit the freed section from falling more than a couple of inches. Then, assuming the tower is resting against the house roof or side, climb atop the house (via a ladder, not via the tower!) and gently straighten up and reinsert the upper section while an assistant keeps pressure on the winch and controls the safety-latch line. This is not a difficult maneuver; it merely requires caution. I've done this single-handed by keeping pressure on the winch while pushing the moving section back straight and then slowly unwinding the cable (and lowering the upper section). I wouldn't care to try this daredevil stunt very often, however.

It's possible that an unexpected killer storm can arise during that once-a-year occasion when an amateur forgets to lower his crank-up tower. Sorry 'bout that (maybe my next article will describe tower straightening techniques). Plan ahead. Either install permanent guys and chocks, seldom lowering your tower, or make tower-lowering part of your amateur activities. A properly maintained tower can be raised or lowered within 2 or 3 minutes, and it's great exercise!

Some of the smaller crank-up towers do not have room inside their top sections for mounting large rotors. Consequently, the rotor must be mounted above the top section. Wind force in this case will be directed against the rotor rather than the tower, since a thrust-bearing arrangement cannot be utilized. Assuming a relatively large rotor and reasonably-sized beam are used, few problems need be expected, particularly if the tower is retracted to minimum height during periods of non-use. In other words, pick your antenna and rotor size according to your use and future plans—and don't overrate their capabilities. A 40-dollar rotor mounted atop a tower can't handle a full-size 20-meter beam!

Crank-Up Tower Maintenance

Crank-up towers, like any mechanical devices, require occasional maintenance for reliable and long-term operation. Basically, this maintenance consists of oiling tower sections at points of friction, oiling the pulley(s), cable, and winch bearings, plus oiling the safety clamp(s) and tightening springs as necessary. Regular 20- or 30-weight auto oil is perfect for this application. A few drops placed at the top of each section's corners will slowly run down the section's length and spread into its runners. This procedure may also be applied to the pulley cable. Finally, guy wires can be rechecked and their turnbuckles adjusted as necessary to maintain exact plumb.

Conclusion

Assuming that safety and maintenance rules are diligently respected, the crank-up tower should prove a cherished accessory for any amateur. Limited height, two-section crank-ups are extremely useful for antenna experimenters or amateurs faced with structure limitations. The beauty of variable-height, accessible support is hard to beat, but don't overlook safety precautions. Antenna accidents are the leading cause of injuries to today's radio amateurs. ■

The Incredible Antenna Mark 2

—a complete HF allbander in a very small space

Seven years ago I wrote an article titled "The Incredible 18-Inch Allband Antenna" (*73 Magazine*, March, 1975). Since that time there have been many variations built. The original antenna had some severe intermodulation problems which made extra signals appear just where you did not want them. My project was satisfactory for locations far from other radio stations, but not good for cities. The Incredible Antenna Mark 2 solves these problems.

The antenna is remarkable because it covers the entire shortwave band from the AM broadcast band up through the 10-meter band and is compact enough to sit on top of any receiver.

This antenna functions very differently from ordinary antennas. Imagine for a moment that any two conductors in the universe form the plates of a capacitor. If they are an inch apart they form a capacitor, and if they are 1,000 miles apart they still form a capacitor. Naturally, the impedance of a capacitor with a 1,000-mile spacing is going to be very, very high. So what we want to do is build a very, very high input-impedance, active-circuit transformer to convert down to normal transmission-line impedances. If a little amplification is done at the same time, so much the better.

Photos by Carroll Haugh

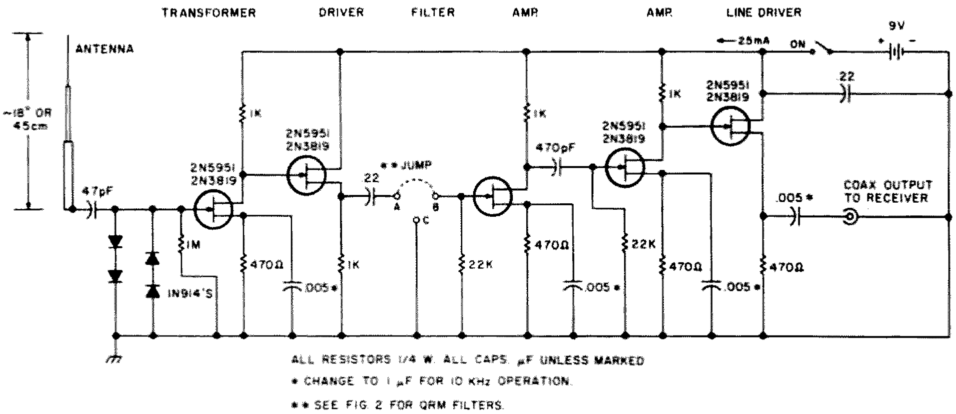

Fig. 1. Schematic for the 18" allband antenna.

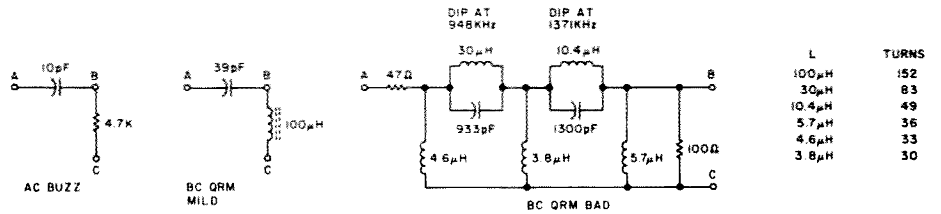

Fig. 2. QRM filters. All coils are ¼" diameter and ¼" long. Use #30 or smaller enamel wire.

The amplification of the improved antenna system shown in Fig. 1 is done by common rf field-effect transistors. Using FETs made a great improvement in the spurious signals. Note the terminals marked A, B, and C. These are for insertion of filters to remove local broadcast stations. Try jumpering A and B together first. If interference shows up, then add the appropriate filter from Fig. 2.

As for building the Mark 2, I used all common disc-ceramic or mylar™ capaci-

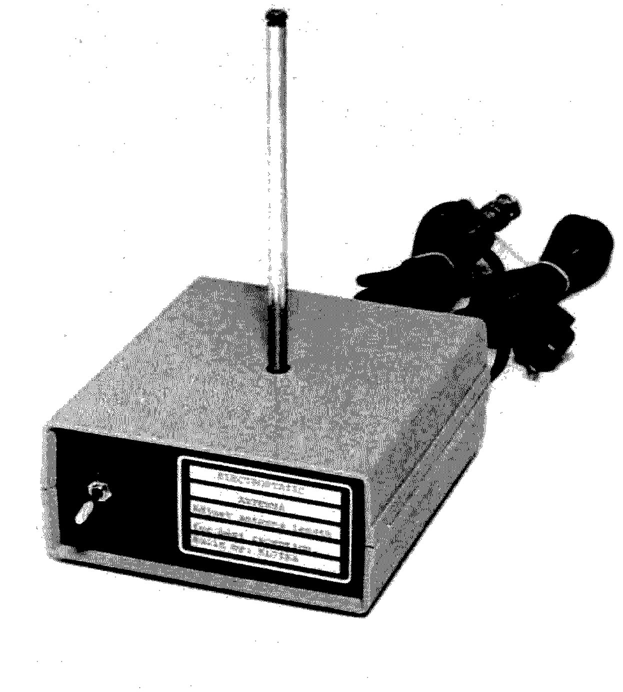

Photo A.

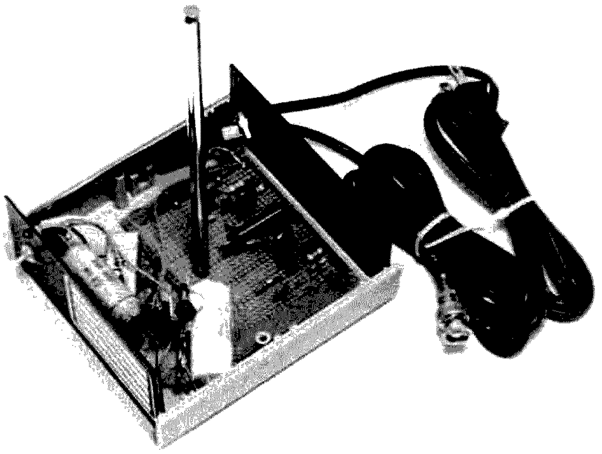

Photo B.

tors, carbon-film resistors, and FETs purchased from the local Radio Shack store. (I recommend 2N5951 FETs if you can get them, but 2N3819s do work.) All of this is mounted on perforated phenolic board. Leads should be kept short as is conventional in rf practice, and I used a number 18 AWG wire to form the ground bus. Make sure that there is as little capacity between the antenna rod and ground as possible. Don't use coax between the board and the rod; use an old-style ceramic feedthrough insulator for the rod or at least a large plastic support to keep the ground capacity low. I found that a replacement-type antenna designed for a transistor radio was ideal because it allowed me to adjust antenna length to reduce local interference.

If you are wondering about adding a power supply, watch out for electrostatically-induced hum. The voltage can be anywhere between 9 and 14 volts, but it is necessary to bypass the ac line to the antenna ground or, even better, use a wall-mount, calculator-style power supply. Internal power supplies will require that you shield the transformer and power line. If this is not done, then you will have CW signals modulated by ac hum. The easiest power supply is a good 9-volt battery.

Last time I wrote about the antenna, some low-frequency SWLs wanted to know if this would work all the way down to 10 kHz. The answer is yes, but only if the .002-uF capacitors are changed to 1 uF. Naturally, it becomes much more prone to power-line noise when you do this, and I don't recommend it unless you need the additional coverage. Using a very narrow-band receiver, I have been able to receive a Ft. Collins, Colorado, audio frequency station, but it was only marginal on an 8-foot rod.

I figure this project will cost $25 and two evenings, one to get the parts and another to build the antenna. It will open the lower frequency ham bands and the international shortwave bands to everyone with a receiver. I'm already working on the next version for use in my car with an integral noise blanker. ■

Parts List

1—1 megohm, ¼ W

1—Perfboard (276-158)
1—Battery snaps (270-325)
1—Box, plastic (270-218)
1—Antenna replacement (15-232)

(Radio Shack numbers given.)

If you really want to figure out how much capacitance there is between two identical rod antennas, then solve the following simplistic equation for a 10-cm spacing, and then for a 100-km spacing. For the academically inclined, the results are worth the effort. With L = length of wires in meters, D = spacing in meters, r = wire radius in meters, and C = capacity in pF, then

$$C = 17.7\pi L \left\{ \mathrm{Cosh}^{-1}\left[\frac{D^2 - 2r^2}{44}\right] \right\} - 1$$

Where: $\mathrm{Cosh}^{-1}x = 1n\,[x + (x^2 - 1)^{1/2}]$

The Amazing Beam Header

—point it with your Pet

Many of us have beam antennas we use for working DX stations. As you probably are aware, the rotatable-beam antenna is of little advantage unless you know where to point it to work a given station or country. There are maps available which can be used for ballpark estimates of the headings, but I find that these usually are centered somewhere else besides where I am.

I have one of these maps, but I find that to use it I first must determine what country the station is in and then locate the country on the map. The problem is that while I usually hear the DX station call, sometimes I never hear what country he is in; by the time I find the prefix in a country list and locate the country on the map, either the band folds or the station moves on. If you operate a fast-paced contest, you do not have the luxury of taking more than a second or two to point the beam.

It was during one of those contest weekends that I looked over at my Commodore Pet microcomputer and asked myself, "What if . . . ?" What if I loaded a cross-reference list of call prefixes and countries into the computer so it could look up any call prefix and tell me what country it is in? What if I also loaded the latitude and longitude of the country into the computer? Then I could just type in the call prefix and have the microcomputer calculate the proper beam heading.

From that point on, the contest was a total loss. I spent the rest of the weekend (actually the next two weeks of my spare time) on the microcomputer, working on a beam-heading program.

The idea of writing a beam-heading program had crossed my mind a time or two before, and already I had definite ideas of what I wanted. Naturally, I wanted to be able to input a call prefix and get back a beam heading to that call area. As an extra, it would be nice for the computer also to tell me what country I am working. Some call areas are rather large, and the beam heading for one city may be significantly different from that for another city in the same area. So it would be nice if the computer also would give me several cities within a given large country or call area (such as Canada or Mexico).

I work mostly SSB, and many of the phone stations in the US and Canada will give their city and state when they call CQ, so it would be nice to have a look-up by city and state or province. Since I have a printer connected to my computer, I wanted to be able to dump a list of all locations with headings to each. If I had an option to change my location (the location the beam headings would be calculated from), I could run lists for friends in other cities.

The program listed with this article is what I ended up with. It begins by reading the data on each city. This data is illustrated beginning on line 5000 and includes the call prefix, city (and state or province for the US and Canada), country, and latitude and longitude. As you add or delete cities in the data, be sure to put the correct number of cities on line 110. The variable N is used throughout the program in loops to save having to change every loop each time you add or delete a city. A 16K Pet will hold data for about 150 cities. You can get latitude and longitude data from an almanac or a good atlas.

Once the cities are all loaded, the program must obtain your latitude and longitude. It does this by asking for your city and state and looking it up in the data. (Input your city followed by the two-letter abbreviation for the state; do not put a comma between the city and state.) If it cannot find your city and state, it will

```
                CHOOSE AN OPTION

0.  FIND BEARINGS TO GIVEN CALL PREFIX
1.  FIND BEARING TO GIVEN CITY
2.  FIND BEARINGS TO GIVEN COUNTRY
3.  PRINT BEARINGS TO MAJOR U. S. CITIES
4.  PRINT BEARINGS TO MAJOR CANADIAN CITIES
5.  PRINT BEARINGS TO MAJOR FOREIGN CITIES
6.  PRINT BEARINGS TO ALL MAJOR CITIES
```

Fig. 1. This is the menu of options available in the beam-heading program. The options which say "find" will print on the video screen. The options that say "print" direct their output to the printer.

ask you if you want to try another city. If you answer no, it will then ask for you to direct-input your latitude and longitude. From here on out, the program is menu-driven. The menu is listed in Fig. 1. There are seven options in the menu, including four print options and three screen options. For each option, the program searches the data based on the given key (prefix, city, country) and prints or displays what it finds. A sample of what you get on the screen from option 2 is shown in Fig. 2.

If you answer yes when the program asks if you want the data sorted by call prefix (a good idea if you are going to use the printing options), be prepared for a little wait if you have very many locations to sort. I do not pretend to be an expert in sorting, and I did not write this sort in machine language—which would have been faster but more difficult to adapt to different computers. At any rate, it will take a few minutes to sort if you have a hundred or more locations in the data.

What the program must do is find the initial heading for a great-circle route between your QTH and each city in the data. The equations in *The ARRL Antenna Book* turned out to be of little use for me in this program. The problem I had with the ARRL equations was that I needed to take the arc cosine of the angle. My microcomputer's BASIC has only the arc tangent. For the solution to this problem, I went to my trusty math handbook and found a set of equations called Napier's Analogies. The algorithm I developed from this is on lines 1000 through 1320 of the program. It was thoroughly tested before I put it into this program and it works for any two points on the globe.

For those of you who may want to put this program on a microcomputer other than a Commodore, let me mention some small details. First, the CHR$(1) in the heading print subroutine (lines 4000-4140) tells the printer to enhance the print on that line. (A sample page

Program listing.

of the output list is included here which shows this enhanced printer.) The second thing is the trick I play with the input for the options. Before each input statement, there is a print statement which prints what appears to be blanks. They are actually shifted blanks. The input statement then backspaces over the shifted blanks. This means that if you just hit the return key in response to any question, the program will not get a null entry and blow up. Instead, it will get the shifted blanks. It then checks for shifted blanks and recovers to another part of the program.

If you are in one of the options, say the lookup-by-call-prefix option and give a null entry (just hit return), the program will branch back to the menu. If you just hit return in the menu, the program will branch back to requesting your city name. This allows you to change your location without having to exit the program and start over in reading and sorting all the data again. If you just hit return when you are asked for your city, you will exit the program.

I find that this program can help me get contacts I might otherwise miss from not having my antenna pointed in the right direction. It does everything except point the beam for me. Now, let's see, if I can wire the computer into the rotator control box ■

Try the GHz Getter

—a marvelous microwave antenna you can build

I have always been interested in antenna design, and the amateur microwave bands permit experimentation with scaled-down antennas. The short wavelengths permit the testing of designs without a hundred-acre antenna farm. However, a lack of activity limits the testing and application of the antennas. Recently, MDS television service was added to this area, providing a reliable, constant-power microwave signal for antenna testing.

The transmitting antenna is located several miles away—hence it approximates a far field source. (My microwave-antenna range is a second-story window.) The frequency, 2.15 GHz, is high enough to keep the antenna size down to a practical level yet not so high as to make construction tolerances beyond amateur capabilities. Gain comparisons are made by placing an attenuator between the microwave converter and the television receiver and noting how much attenuation must be added or removed to maintain a constant signal level.

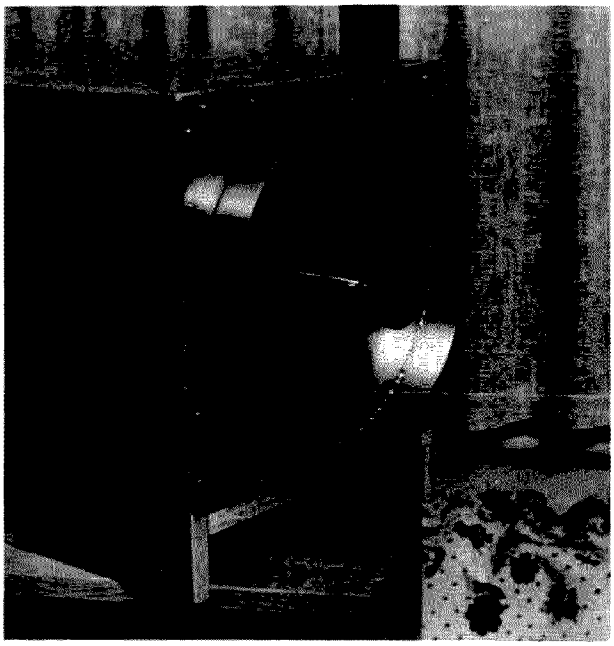

Photo A. Antenna on a test mount.

The first antenna I tried was the popular coffee-can horn. Since then, it has become my standard to which all other antennas are compared. Other horn and helix antennas have been constructed and tested, but have one major drawback: their long length. I decided to try a more compact planor antenna. Collinears and other phased arrays were ruled out because of problems with the phasing lines. Digging through my file on antennas, I ran across the short backfire and constructed the antenna shown in Fig. 1. Several feeds were built and tested. The first used a microstrip disk and offered no better gain than the coffee can. The final feed is the one used on the original design.[1,2] It consists of a slot-fed dipole with a small disk-shaped reflector. The dimensions shown are in terms of wavelength, making frequency-scaling to 1296, 2304, or other frequencies easy.

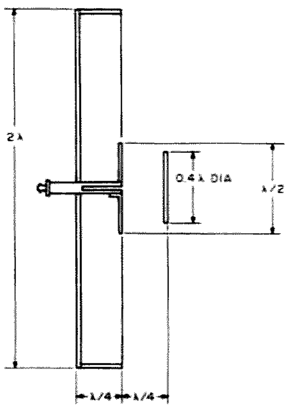

Fig. 1. Short backfire antenna.

The ground plane is made from a 300-mm (1-foot) -square piece of single-sided PC board. Other materials, including screen wire, could have been used. Another piece of single-sided board 35 mm by 864 mm (1⅜" by 34") was formed into a circle and the ends butted together. A small piece of board is epoxied so that it overlaps the joint. After curing, the ring was edge-soldered to the ground plane, forming

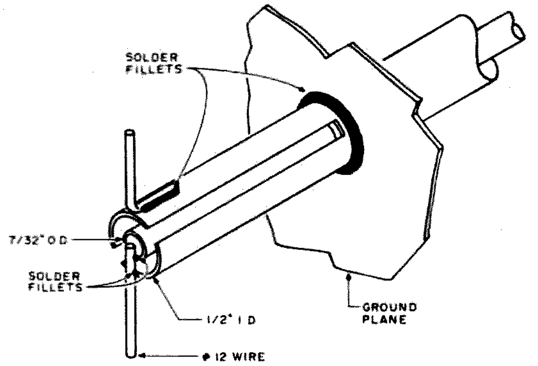

Fig. 2. Dipole-feed details.

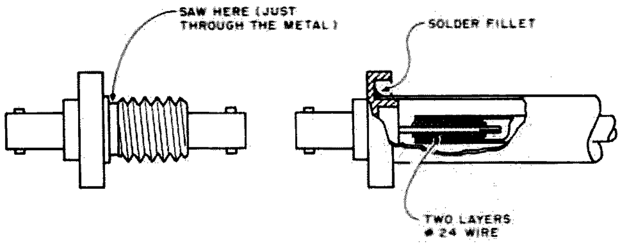

Fig. 3. Connector details.

an open cavity two wavelengths in diameter and one-quarter wavelength deep. I drilled a hole pattern in the cavity center to allow experimentation with different feeds or rotating the feed polarization. The radiation pattern is symmetric with a half-angle response of 30 degrees to the −10-dB level.

The dipole feed is formed from two concentric pieces of thin-wall brass tubing that comes in telescoping sizes at a local hobby shop. The outer conductor has an internal diameter of one-half inch. The inner conductor has an outer diameter of seven thirty-seconds inch. The construction details of the dipole and the connector are shown in Figs. 2 and 3, respectively. Note that one dipole element shorts the inner and outer conductors together. The other stops at the outer conductor.

The dipole feed is assembled by first sawing through the outer sleeve of a BNC bulkhead feedthrough and discarding the threaded portion. The exposed inner conductor is built up with two layers of number 24 bare wire. The brass inner conductor tubing is slotted for about 10 mm, slid over the built-up inner conductor, and the assembly is sweat-soldered together. The inner conductor is intentionally left too long and will be trimmed later.

Next, the outer conductor is cut to length (not critical) and slotted. The two slots are each one-quarter wave long. Slotting is best done by first inserting a one-half-inch diameter dowel rod in the outer conductor to prevent buckling. The slot width is a nominal one-sixteenth inch. The outer conductor is then slid back over the inner conductor assembly and the inner conductor length is marked. After trimming the inner conductor and removing any burrs, the assembly is joined together with a solder bead around the coax fitting. A hole slightly larger than the outer conductor is drilled in the center of the ground plane or support plate if you intend to make interchangeable feeds. The outer conductor is soldered in place with the slot roots flush with the front surface.

The dipole elements are added last. They are made from number 12 bare wire. The element that shorts the inner and outer conductors doubles as a support for the inner conductor. The subreflector disk is epoxied on two half-wavelength-long wooden posts. I used wood instead of polystyrene because it was convenient.

Although adjustments aren't normally required, it should be easy to replace the dipole wires with telescopic tubing to permit fine tuning. My tests show that the short backfire has a gain of 8 to 9 dB over the horn, a level between large, high-gain antennas and simple dipoles. ■

The Multiband Vertical

—an aesthetically pleasing antenna with a punch

Space limitations often dictate the use of a vertical antenna on city lots. After a recent move, I found myself faced with this kind of situation. But not only was there insufficient space for any kind of horizontal antenna, there wasn't even room enough for a ground-radial system for my proposed vertical! Putting the thing on the roof was just out of the question. The landlord wouldn't allow any defacing of the physical plant.

In order to get on the air with any sort of efficient radiator, I would have to build it to meet the following set of requirements:

- It had to be put on the smallest possible amount of real estate, preferably only a few square feet.
- It could not have any ground-radial system (a condition essentially dictated by the above requirement).
- It had to be relatively unobtrusive—no complicated set of spears or prongs or guy wires—lest somebody complain and start imagining all sorts of horrible RFI.
- It had to be efficient, since my intent was to run QRP.
- It had to cover 20, 15, and 10 meters.

This may sound like a mutually exclusive set of parameters, but it's not!

The Vertical Dipole

The antenna described here is a multiband vertical dipole. It was developed as a modification of the familiar ground-plane antenna shown in (a), Fig. 1. A ground-plane antenna, elevated so the feedpoint is at least a quarter wavelength above the ground, requires only a few resonant (quarter-wave) radials in order to have excellent efficiency and low-angle radiation. But suppose that, instead of the radial wires shown at (a), a single length of tubing is used, as shown at (b)? A 20-meter antenna of this va-

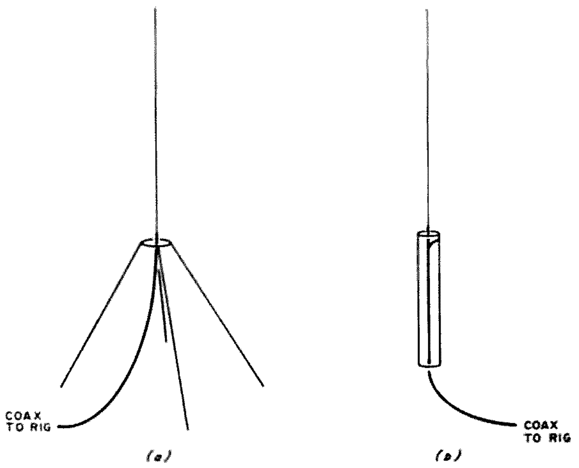

Fig. 1. (a) The conventional ground-plane antenna, with a quarter-wave vertical radiator and three quarter-wave radials. (b) A modification of the ground plane where the radials are replaced by a single quarter-wavelength section of tubing through which the feedline is run. The center conductor of the coaxial feedline should be connected to the top section in both cases.

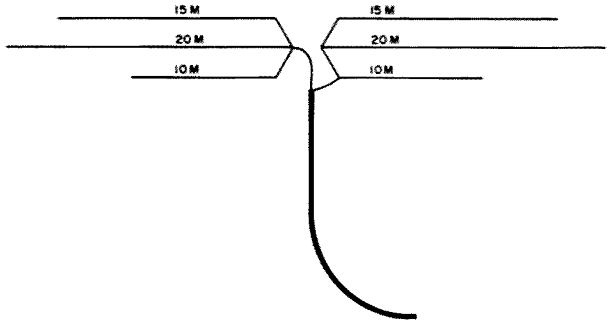

Fig. 2. Connecting three dipole antennas in parallel to get three-band operation. On a band where one of the dipoles is half-wave resonant, the other two are nonresonant and thus do not contribute to the system in any way.

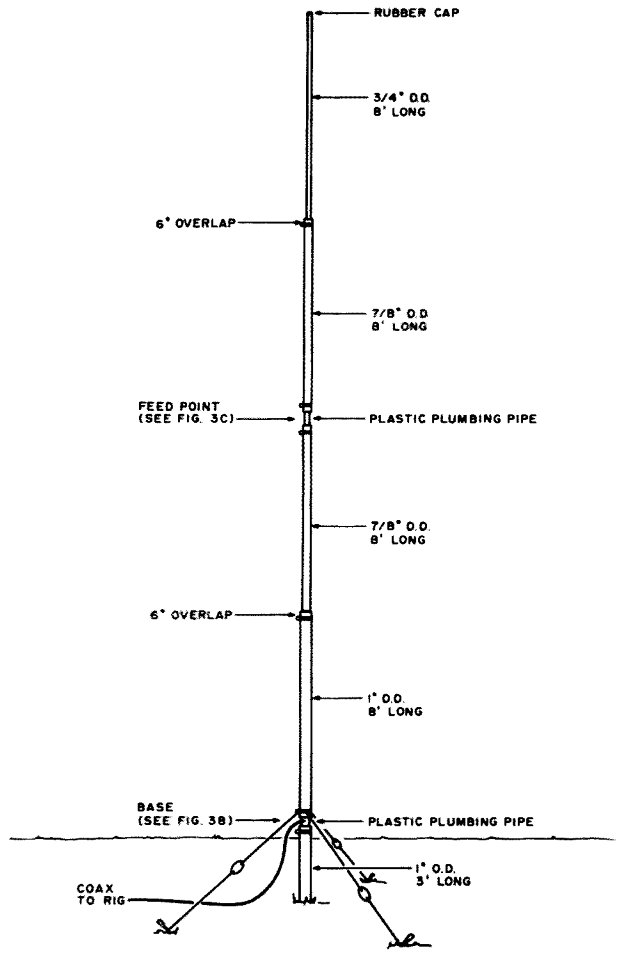

Fig. 3 (a). The overall construction of the 20-meter main support is shown. The tubing is slit and clamped together with hose clamps. Overall height, assuming the base is 2 feet above ground level, is just over 33 feet.

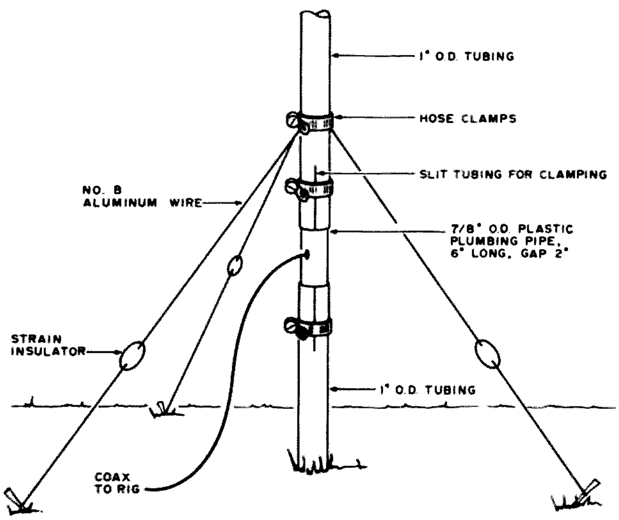

Fig. 3 (b). The base mount, showing the 20-meter pruning wires which act as reinforcement for the plastic pipe.

riety was constructed and tested at W1GV/4 and was found to perform exceptionally well.

How does an antenna such as that shown in (b), Fig. 1, work? Actually, it can be thought of as simply a ground-plane antenna in which the set of radials is brought straight down from the feedpoint. It may also be thought of as a vertical dipole in which the feedline is brought in from the underside, directly through the lower radiating section. However you want to visualize this antenna, though, it works—well!

Multiband Operation

One of my requirements for this antenna was that it have multiband capability. Because of the feed method, adding traps did not appear feasible. (It would not be a good idea to run the coax through the trap inductors.) One technique, commonly used with home-brew multiband dipole arrangements, came to mind: Simply place the dipoles for each band in parallel. Fig. 2 illustrates this scheme.

This kind of antenna will work very well on 20, 15, and 10 meters; on each band, the antenna cut to the proper length would accept and radiate electromagnetic energy, while the other two antennas would not, since they would be poorly matched. The result would be good low-angle radiation and true ½-wavelength resonance on all three bands.

The only possible problem seemed to be how to physically construct the "multiple vertical dipole" antenna. This proved easy, requiring only a modification of the existing 20-meter vertical dipole.

Construction of the Main Support

Fig. 3(a) shows the construction of the 20-meter antenna which forms the main support for the structure. Aluminum tubing is used for the radiating elements, with 1-inch o.d. at the bottom tapering to ¾-inch o.d. at the top. The 8-foot sections overlap 6 inches, so each side of the dipole is 15 feet 6 inches high. To obtain exact resonance, three short lengths of No. 8 soft aluminum ground wire are attached to the base, as shown. They should be trimmed so the swr is minimum at the desired frequency. A good starting length for the wires is 18 inches. Strain insulators should be used so the wires can provide extra support for the antenna base; otherwise, high winds might cause the antenna to blow down. (It's over 30 feet high!)

Fig. 3(b) is a close-up drawing of the base mount. A short piece of ⅞-inch o.d. plastic pipe is used to insulate the antenna base from the ground. The feedline, consisting of RG-58/U coaxial cable, is fed through a 5/16-inch hole in the side of the pipe, upward inside the lower part of the antenna, to the feedpoint.

Fig. 3(c) shows the construction of the center feedpoint. A short section of ¾-inch o.d. plastic pipe is

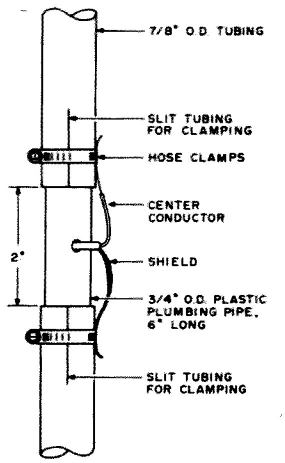

Fig. 3 (c). The feedpoint. To reduce the chances of corrosion, the entire feedpoint connection should be wrapped with electrical tape before the hose clamps are installed.

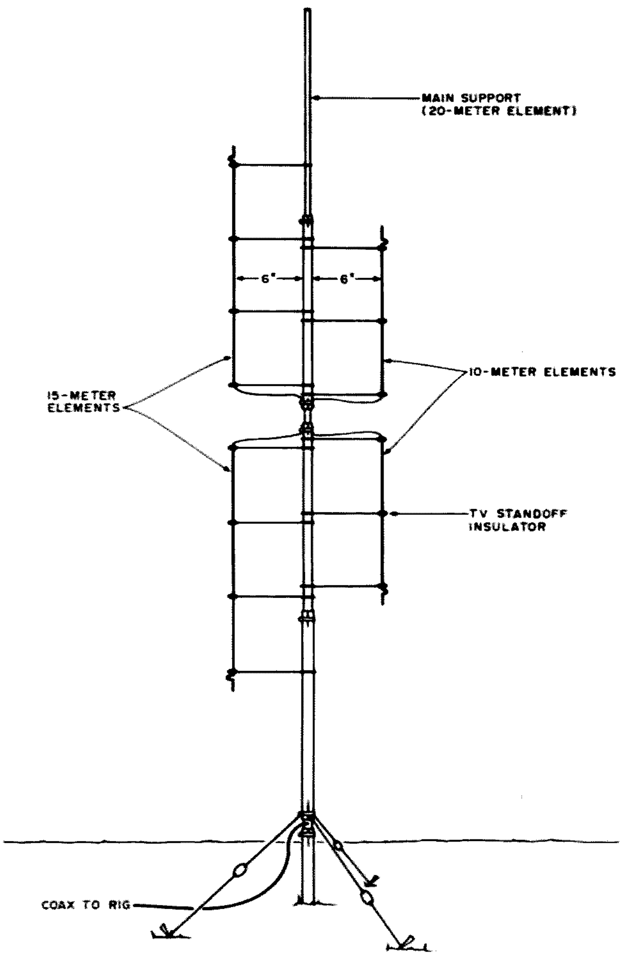

Fig. 4 (a). Overall picture of the completed vertical dipole. The 10- and 15-meter elements are spaced 6 inches from the main support.

used. Drill a 5/16-inch hole in the side of the pipe at the center, as shown, and bring the coax out. The shield is connected to the lower part of the antenna, and the center conductor to the top, via those convenient hose clamps. It's a good idea to tin the exposed leads with solder and wrap the entire connection with electrical tape before clamping. Those hose clamps serve to hold the antenna together mechanically as well as electrically, so be sure to put them on tight. You might even want to put a separate pair of clamps on the tubing independent of the electrical connections to ensure rigidity of the structure.

Since this antenna is quite large, it is important that the base mount be properly assembled. The tubing at the bottom should be driven at least 12 inches into the ground. The set of resonator/guy wires should be tight, have a slant of at least 45 degrees to the vertical (less than 45 degrees to the horizontal), and their anchors should be *very* secure. Also, don't forget the little rubber cap at the top of the thing! Little details like this could be responsible for an early demise if neglected.

Adding 15 and 10 Meters

Fig. 4(a) shows the complete antenna, illustrating the installation of the 15- and 10-meter elements. The 15-meter elements should be precut to 11 feet 2 inches; the 10-meter elements should be precut to 8 feet 6 inches (some shortening will be needed to resonate them). The 15- and 10-meter elements are made of No. 8 soft aluminum ground wire and are spaced from the 20-meter main support on opposite sides, as shown, using 6-inch clamp-on TV standoff insulators. Care must be taken to see that the wires do not come into contact with the 20-meter element, except of course at the feedpoint. Electrical contact at any other point will disturb the resonance on 15 or 10 meters. The wires must be pulled tight, and they must not touch the metal rings on the standoff insulators.

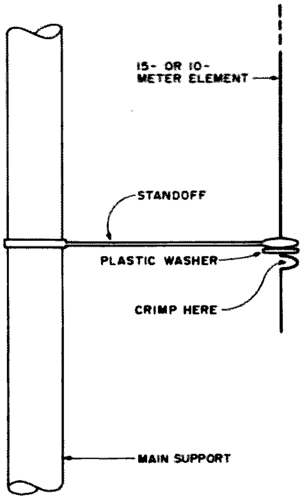

Fig. 4 (b). Method of securing the ends of the wire elements. A few inches should be left free for pruning.

The element ends are secured as shown in Fig. 4(b). Crimp the wire slightly, as shown, after sliding a plastic washer of at least 1½ inches diameter around it to prevent short-circuiting to the standoff ring. Leave about 10 or 12 inches of wire past the standoff for pruning purposes.

When trimming the elements, it will be necessary to raise and lower the antenna, since both the bottom and top elements must be cut to the same length. The final length will depend, to some extent, on how close the antenna is to trees and other obstructions. (The antenna should be located so that it cannot fall on utility lines!)

Theoretical element lengths (for each side of the dipole) are given in Table 1 as a function of frequency on 10 and 15 meters. At W1GV/4, the elements were trimmed for 21.100 and 28.500 MHz, and the lengths turned out to be about an inch shorter than the theoretical values on both bands. This was probably because of the abundant foliage on the property.

If you find that the resonant lengths appear nowhere near the values given in Table 1, first check to be sure that there are no short circuits to the main element. If there are none, you might have antenna currents on the feedline.

Decoupling the Line

Since this is an unbalanced antenna, meaning it is not symmetrical with respect to the feedline, it is possible that there may be rf currents on the shield of the coax. This is especially likely if the feedline happens to be a multiple of an electrical half wavelength on the operating frequency.

To decouple the line, the first thing to do is make certain that the length of the line is as far away from resonance as possible on all three bands simultaneously. Fig. 5 shows some of the best lengths, as well as those lengths that should be avoided. (Note that a feedline length of 66 feet is especially bad since it is resonant on all three bands!)

If this technique does not solve the problem, then you will have to install a choke in the line. To do this, simply wind the coax about 20 times around a piece of 2-inch o.d. plastic pipe, securing the coil in place with electrical tape. The choke should be placed at the

point where the feedline enters the base of the antenna. After the choke has been wound, the remaining length of line to the rig should be nonresonant, as shown by Fig. 5.

A choke coil should be required only if high power is used, since the probability of getting rf in the shack increases with the power output of the transmitter.

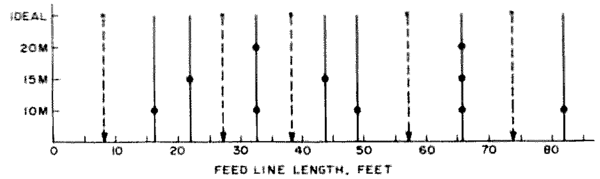

Fig. 5. Feedline resonant lengths are shown by dots and solid lines; these lengths should be avoided. Ideal lengths for a 20-, 15-, and 10-meter feedline are shown by an X with a dotted line. Resonant frequencies chosen for this chart are 14.175, 21.225, and 28.500 MHz, representing an approximate median for each band.

Frequency (MHz)	Element Length
21.000	11'2"
21.100	11'1"
21.200	11'0"
21.300	11'0"
21.400	10'11"
28.000	8'4"
28.250	8'3"
28.500	8'2"
28.750	8'2"
29.000	8'1"
29.250	8'0"
29.500	7'11"

Table 1. Theoretical resonant lengths for each side of a dipole antenna as a function of frequency. These lengths are approximate because of possible capacitive loading effects from nearby objects. Lengths are to the nearest inch. These values are measured from the feedpoint connection along the wire to the end of the element.

Performance

Using only 10 Watts output, many contacts have been made on all three bands. The low-angle radiation of this antenna appears to be exceptional, which is to be expected of a vertical dipole. The current loop is elevated about 17 feet above ground; this helps reduce absorption by nearby obstructions.

Particularly on 10 meters, where very little power is needed to produce DX, several European countries have been worked, often when competing against stations using yagis or quads and much more power.

The swr at resonance is better than 2 on all bands. It gets up to about 4 at the top end of 10 meters, since I adjusted it for 28.500 MHz. No matching network has been necessary to obtain proper transmitter tuning in normal operation.

Adding More Bands

It should not be difficult to add elements for the new bands at 18 and 24 MHz once they are opened for amateur use. These elements could simply be placed in parallel with the other three antennas.

There appears to be some possibility that, by adding enough elements of progressive lengths in parallel, it might be possible to build a broadband antenna capable of continuous coverage between two set frequencies. There are some structural problems involved with this, but I am presently working on the idea. If the results are good, I will present them in a future article. ■

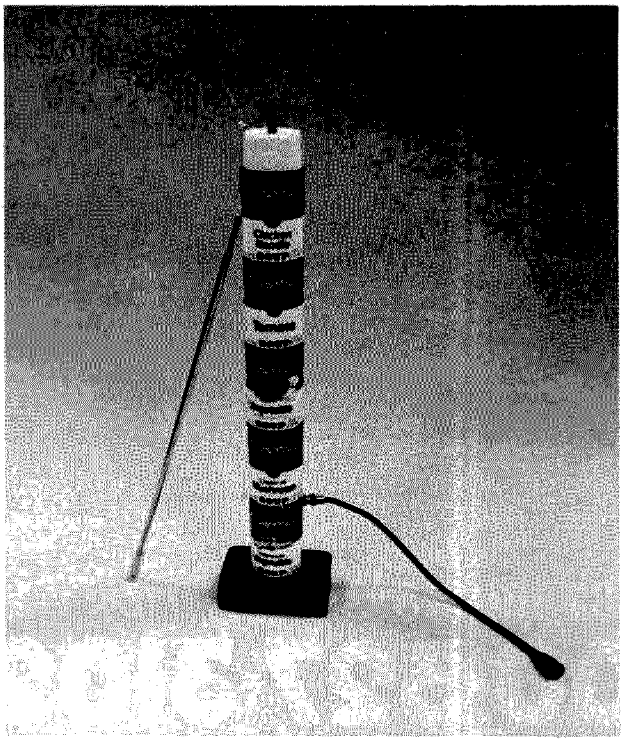
The Campbell J

—a little antenna that "can"

Carlton Moseley W4YVY
1612 Colony Drive
Tarboro NC 27886

The Campbell Soup can antenna is a variation of the familiar J antenna. Four advantages of the soup can antenna are: (1) its unique construction uses many parts from around the house, (2) it can come apart for portable operation and storage, (3) the matching section is unbalanced to match coaxial feedlines, and (4) the matching section has immunity to detuning by nearby objects. Like the J antenna, the soup can antenna gives 3 dB gain over a ¼-wavelength whip because it uses a ½-wavelength radiator.



Two-meter soup can antenna.

Background

In a J antenna the bottom ¼ wavelength is a parallel transmission line used for matching. This matching section is shorted together at the bottom to give a zero impedance. Then, due to the transformation of a ¼-wavelength transmission line, the top of this ¼-wavelength matching section has a very high impedance. This very high impedance matches the impedance of an endfed ½-wavelength antenna. By tapping up on the ¼-wavelength matching section, a point can be found for the proper impedance match for the feedline being used.

The Campbell Soup can antenna, like the J antenna, uses a ¼-wavelength matching section, but in the Campbell Soup can antenna, the matching section is a coaxial line. The bottom of the soup can coaxial matching section is shorted together to give a zero impedance. Then ¼ wavelength above the zero impedance is, once again, the very high impedance needed to match an endfed ½-wavelength antenna.

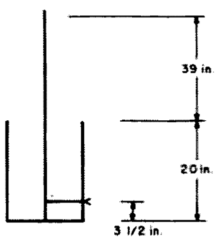


Fig. 1. Two-meter soup can antenna dimensions.

Because of the coaxial design, this matching section can be fed with coaxial line without upsetting a balanced condition. Also, being coaxial, if metal objects are near the matching section, they will not upset the matching section operation.

Construction

Both ends are cut out of 3 of the Campbell Soup cans. These will be used in the middle of the coaxial matching section. For the top can of the coaxial matching section, one end is completely removed and the other end is cut out except for a ¼-inch-wide lip.

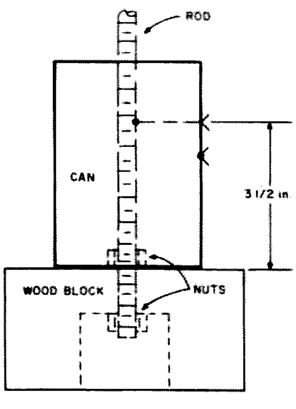

Fig. 2.

Later this lip will be the support for the plastic spray can top. For the bottom can, one end is completely removed and the other end has a hole cut in it to just pass the 5/16-inch threaded rod.

The wooden block should have a hole bored through it that is just big enough to pass the 5/16-inch threaded rod. The bottom of the block should have a larger hole countersunk in it to hold a nut and washer.

The bottom soup can is mounted on the wooden block using the threaded rod. The soup can is turned so that the end with the small hole is next to the wooden block. A nut and washer in the soup can and another nut and washer in the countersunk hole of the block will hold the items together. The rod should not extend below the block so that the block can sit on a surface and not scratch it.

A coax chassis connector is mounted on the side of the bottom soup can about 3½ inches from the bottom. The center conductor of the coax connector is attached to the threaded rod 3½ inches from the bottom of the soup can. It can be soldered, but a convenient method is to wrap a wire around the rod and hold it in place between two nuts and washers.

The remaining 4 soup cans are soldered together with the top soup can on one end with the lip away from the other cans. Next the 4 soup cans are soldered to the bottom soup can so that the lip of the top soup can is on top.

The top of the soup cans and the top of the threaded rod must be held rigid yet be insulated from each other. The plastic spray can top is used for this. A hole is cut in the spray can top so it will just slide over the threaded rod and then rest on the lip of the top soup can. The plastic spray can top can be held in place between two nuts and washers or, better yet, by one nut and washer screwed down tight. A piece of sheet plastic or thin wood will also work as an insulator and support.

Finally, the replacement automobile antenna is mounted on top of the threaded rod. Most replacement auto antennas designed for stud mounting have setscrews that will hold them in place.

MATERIALS REQUIRED

- 5 Campbell Soup cans (or any other can 4 inches tall and about 2-1/2 inches or less in diameter)
- 1 5/16-inch threaded rod, 24 inches long (available at most hardware stores)
- 6 nuts for the 5/16-inch threaded rod
- 6 washers (use with the 6 nuts if desired)
- 1 adjustable replacement automobile antenna that will fit over the 5/16-inch threaded rod (the rod or antenna size may be varied to get a combination that will fit together)
- 1 two by four wood block, 5 inches long (this block size may be varied to suit the builder's needs just as long as the block is large enough to support the soup cans)
- 1 coax chassis connector (BNC type or SO-239)
- 1 plastic spray can top approximately 2-7/16 inches in diameter that will just fit inside an empty soup can (see text)

Adjustments

The only adjustment is to adjust the length of the auto antenna. A length of 39 inches is needed as measured from the top of the top soup can to the top of the auto antenna. ■

Avoid an Electrical Nightmare

—sidestepping ground faults

A. R. Taylor W5OS had a very interesting article in the February, 1981, issue of *73* titled, "Stalking the Elusive Ground Fault." He went through anxiety trying to correct the situation. What was the situation? Simply, he had extra-high voltage on one side of his three-wire 240-volt system and very low voltage under load on the other side.

The high-voltage side burned out his fluorescent light (in flames, actually) and burned out the transformer in an electric clock-radio. The other side of the 120-ground-120-volt system had such a low voltage under load that his freezer and refrigerator would not run. However, with those two devices pulled off the circuit, his lights on that 120-volt side would work.

What happened is not common, but happens occasionally when aluminum wire is used between the power-line pole transformer and the house circuit. It happened to me after I moved into a newly-constructed home with a brand-new service connection. *It is potentially dangerous!*

The symptoms in my case were the sudden brightening of reading lights which when turned off and then on again would work satisfactorily. A similar symptom occurred in another room with sudden tremendous brilliance of the lights and increased intensity of the TV picture. A transformer in the house heating system burned up and was replaced under warranty. At the time, it was thought it was a defective transformer since it was a brand-new installation.

The problem was definitely intermittent and, of course, did not show on a recording voltmeter that the power company put on the house line for 24 hours; those tests never work when you want them to. At times, I could measure *220* volts on one side of a 120-volt circuit and practically zero on the other side, but it would become normal if any load were changed.

Let's stop a minute and see what is happening; it definitely is a ground fault, whatever that means at this point in the story.

Fig. 1(a) shows a 240-volt, three-wire system with a 100-Watt lamp on one side of a 120-volt line and a 1000-Watt toaster on the other side of the line. From Ohm's Law we find that the resistance of the lamp and toaster using 120 volts is: ($R = E^2/P$) $R_{lamp} = 120^2/100 = 144$ Ohms; $R_{toaster} = 120^2/1000 = 14.4$ Ohms.

A ground fault occurs when the ground connection at the supply transformer opens—see Fig. 1(b). We still have our 240 volts, but it is across the light and toaster which are now in series. How much current flows through that series load? $I = E/(R_L + R_T) = 240/(144 + 14.4) = 1.52$ Amperes.

More important, however, is the voltage across the lamp and the toaster, individually. $E_L = I_L \times R_L = 1.52 \times 144 = 218.9$ volts; $E_T = I_T \times R_T = 1.52 \times 14.4 = 21.9$ volts.

Now do you see why the lights get so bright and the toaster appears not to be working? Do you see why the fluorescent light burned up and the freezer would not work?

After I performed the above arithmetic, I knew why a filter capacitor in the high-voltage power supply of my TS-520 shorted and had to be replaced as well as all the other phenomena that occurred. Incidentally, I now have the TS-520 on its 240-volt connection across the 240-volt line instead of using 120 volts.

The situation came to a head one day when the fault continued regardless of switching loads on or off. A call to the utility company brought a quick response—a crew of three men. After all, if a burned-down house can be traced to a fault by the power company, it creates a problem for them. Actually they really do want to keep satisfied customers.

The fault continued long enough for them to test and assure themselves that it was not a house wiring problem; then the fault magically disappeared. They knew what to do, though. They climbed the utility pole upon which the 2700-to-240-volt transformer was mounted and inspected all the connections from it to the three-wire service line.

Sure enough, the ground connection was unsatisfac-

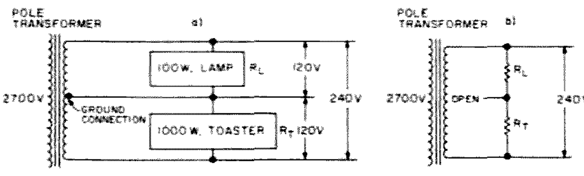

Fig. 1. (a) 120-volt load distribution. (b) Results of open ground connection on 120-volt circuits.

tory. They installed a new connector and assured me no additional problems would occur. Over two years have gone by and none has. Since the three-wire service to the house is aluminum wire which is prone to produce a high-resistance corrosion layer on its outer surface, you can be sure that I will have that connection checked at the slightest indication of a ground fault occurring again.

A number of you with new homes will say, "I have a ground-fault circuit tester on my house switch panel." That will be true but, unfortunately, we are talking about two different things.

House wiring for each 120-volt circuit consists of three wires. A black insulated wire is described as "hot" since it is energized at all times. The white insulated wire conducts no electric current unless the circuit is connected, i.e., a switch is "on." The white wire is called "neutral." The third wire is the grounding wire and connects all the metal parts in the wiring system to earth through the cold-water piping or a pipe driven into the ground. Items grounded include metal outlet and switch boxes, metal conduit, metal cases of stoves, refrigerators, and washers. A three-prong appliance cord continues the grounding all the way to the outer shell of a test instrument or hand power tool. Any fault in such an appliance, as a loose wire or worn insulation touching its grounded metal frame, will cause a house fuse or circuit breaker to trip. Appliances or tools that do not have this protection are dangerous—you could get a shock if something should go wrong with the internal wiring.

Many homes have a Test button on the service panel which when pressed will open the circuit being tested, indicating that no ground fault exists.

Perhaps it would be better to describe the outside service problem as "an open ground return," and not a ground fault, although it is. However, know the difference!

It is worth repeating: An open ground return in a three-wire, 240-volt system will put unusually high voltages on certain loads of the house system which may cause them to overheat, burst into flames, and destroy your home. Be aware of the symptoms and cure. The total destruction at my home before correcting the problem was as follows: 1) power transformer in heating system, 2) smoke detector connected to house line, 3) high-voltage capacitor in TS-520, 4) power supply in garage door opener, 5) vertical linearity in TV set.

Those low voltages may be just as dangerous where refrigerator or washing machine motors are concerned. Insufficient voltage will prevent them from running, thus preventing them from producing a back emf to raise their effective impedance. They will present a low dc resistance to the line voltage, perhaps drawing abnormal current, heating up, bursting into flames, and who knows what then.

It makes me a little apprehensive when I go on a vacation. Have I disconnected *all* appliances? But can I? No, because I like to have programmed lights go on in various rooms at night to indicate occupancy. Probably those lights would burn out fast at 218.9 volts before any damage could be done. But what about the 120-volt smoke detector? Yes, and how about that little door-bell transformer nailed to the cellar ceiling floor beam: That's never turned off! ■

Fine-Tune Your IC-280

—15-kHz step rate got you down?

The versatility, quality, and plain good looks of Icom's 2-meter equipment have made this line very popular. The IC-280 is the epitome of all these traits. One feature is the well-thought-out system used for tuning. By spinning one continuously detented knob, the operator is able to quickly scan from 143.90 through 148.11 MHz. When tuning, an optical chopper causes the microprocessor control chip to update the multiplexed digital readout and tunes the phase-locked loop with a digital coding. The phase-locked loop increments or decrements in 5-kHz steps except in the 146-to-148-MHz range. Here, it hits all the normal and tertiary repeater channels in 15-kHz steps.

In an area where the repeater density is not too high, it's been my experience that any and all frequencies in between the active repeater channels are fair game and are used frequently for simplex operation. It invariably seems that when I'm asked to go to a simplex frequency from a repeater, I'm always 5 kHz off with the IC-280.

To correct this problem, I found that I could modify the digital coding on the MHz lines from the microprocessor, IC7, to the PLL. This fools the microprocessor into thinking it's tuning 144-145 MHz in 5-kHz steps when the PLL actually sees 146-147-MHz frequencies. This is a reversible change and does not add any external switches or accessories that would distract from the clean looks of the IC-280.

The MHz data line logic from the microprocessor to the PLL is shown simplified in Fig. 1. It can be seen that the difference between 144-145-MHz data is the logic on lines B3 and C3.

I decided originally to use the circuit shown simplified in Fig. 2 to modify the data lines. By hard-wiring the transmitter in the 10-Watt mode, the HI-LOW button on the front panel becomes available for controlling the gate operation. In the normal position, B3 and C3 data would not change through the gates. When a high is placed on the switch, the exclusive OR gating will reverse the data levels on the two lines going to the PLL.

After spending several evenings experimenting, I found the parts required to interface a 4070 quad exclusive OR chip into the circuit were more than I wanted to use.

I finally decided that even with all the CMOS IC sophistication, a simple DPDT relay would do the same thing. I settled on a Potter and Brumfield type HPS microminiature DPDT relay. It measures only .41" × .81" × .41". Mine has a 24-volt coil but keys reliably with as little as 10 volts. Twelve-volt relays are available in this line. Using contact cement, I placed mine on the underside of the groundshield that covers IC3 on the PLL board. The relay pins extend out from under the cover by IC6. All connections are soldered directly to the relay pins. Fig. 3 shows the relay wiring. Solder the jumpers before cementing the relay can down.

Remove the gray wire from the main unit board printed circuit pad marked HI-LOW. Pull the wire back through the clear plastic spaghetti and reroute it for connection to the relay coil. This wire is from the HI-LOW switch. Ground the other side of the relay coil.

Jumper the HI-LOW solder pad to ground. This sets 10-Watt operation of the transmitter. With it left open, you would have constant 1-Watt operation.

Find connector J4 on the

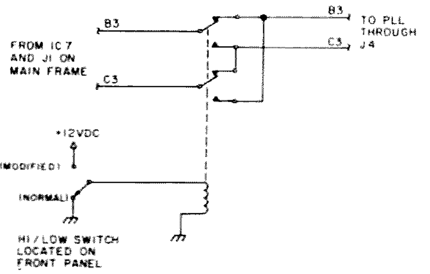

Fig. 3.

PLL board. The red and brown wires on this connector are B3 and C3 coming from J1 and the microprocessor in the remote head. Snip them, leaving enough wire on the J4 side to solder to the relay. They go through J4 to the PLL.

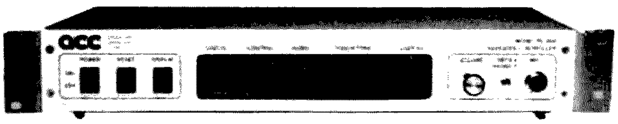
Extend the remaining red and brown wires from J1 a few inches and solder to their respective relay pins.

Remove the remote transceiver head, its cover, and the speaker. Find the open lug on the HI-LOW switch and solder a wire between it and the switched 12 volts on the power switch.

Dress and check all the wiring to the relay and reassemble the transceiver.

By pressing the HI-LOW switch to the LOW position, B3 and C3 lines are reversed. 144 on the display is actually 146. 145 is actually 147. The 100-, 10-, and 5-kHz digits are correct. Notice that 143 and 148 MHz remain unchanged. By releasing the HI-LOW button, normal operation is restored.

I no longer miss all that 146-147 simplex! ■



The New Standard in High Performance Repeater Control...

☐ FRIENDLY, POWERFUL, EASY TO USE - Human engineered to be your "assistant" at the repeater, with capability second to none.

☐ REMOTELY CONFIGURABLE - Change command codes, messages, tone characteristics, timing, and more, remotely! Reliable storage in E²PROM.

☐ Room to grow: BUILT IN! - Features intelligent remote control and meter readback. Interfaces to synthesized remote bases and links. Planned software upgrade path.

☐ SUPPORT -We invented the "Computer Controlled Talking Repeater," so we know how to provide the applications assistance, and long term support so crucial to a computer based product.

☐ BRING YOUR REPEATER SYSTEM INTO THE 80'S - Starting at less than $1200!

The RC-850 Repeater Controller!

A Gem of an RIT

—customizing the receive on the SB-104

Two or three years ago I bought a new Heath SB-104, and after getting it all together found that I needed some sort of RIT feature. RIT (receiver incremental tuning) can be very helpful in a roundtable when one of the stations in the group is slightly off frequency and you need to tune in the station a little better. When this is done, however, the other station or stations will retune to you, and after a few rounds of this you find everyone has migrated several kilohertz away from the original frequency.

Or—and this is my situation—voice characteristics are such that the other station thinks you should sound a little higher or lower in frequency and the operator retunes slightly. The net effect is the same in both cases, and some means of effecting receiver fine-tuning without changing the transmit frequency is desirable if not necessary.

Heath offers a separate vfo (variable frequency oscillator) so one could get in the one unit the capability of changing a receive frequency without changing the transmit frequency, and be able to operate split frequency in the same band. Split operation is common enough in DXing and in some contests, but for general use it is just another control to manipulate. At first, I used a Kenwood separate vfo with my 104, and since it had built-in RIT, it was used almost exclusively. (For those interested in such a scheme, see my article, "The Heath/Kenwood Connection," *73 Magazine*, April, 1979.)

When a friend wanted my Kenwood vfo for his 520, I began to develop a more direct RIT system, one which could be integrated into the 104's vfo circuit and still not drastically alter the rig's appearance. In the experimenting, I found that not only could I get RIT, but that there was some "fallout" extending into a few other areas which are of interest to amateur operators.

Simple Simple RIT

Designed into the Heath 104 vfo is an LSB (lower sideband) shift system to keep the readout of the operating frequency from changing when going from upper to lower sideband. This is only a nicety since the 104 gives a totally corrected readout of frequency, computed from the various oscillators in the transceiver. LSB shift seems nothing but a carry-over from the days when—mechanical readouts of operating frequency making it necessary—the operator did not have to recalibrate when he changed sidebands on moving from one band to another.

After a little experimentation, I found that the LSB shift signal going into the vfo could be used for RIT. A switching diode is used in this circuit to effectively bring some added capacitance into circuit in the vfo, thereby changing the frequency by a small amount. The total change in frequency on the 104 was 1.9 kHz, and this meant about plus or minus 950 Hz, after

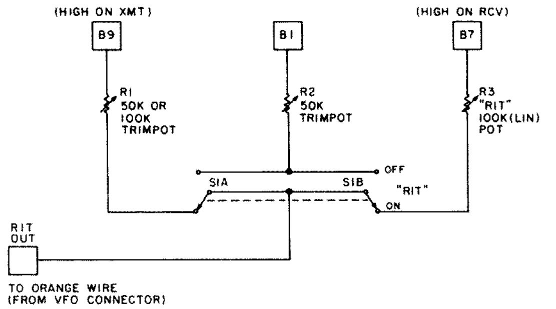

Fig. 1. Simple² RIT.

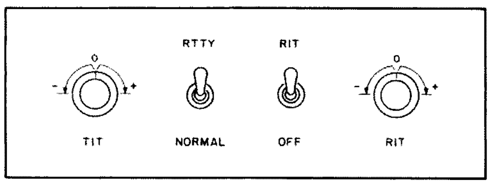

Fig. 2. Deluxe RIT.

the LSB shift cap in the vfo was adjusted so that this much swing could be obtained—quite enough for RIT purposes.

I thought about changing the diode for a varactor diode, etc., and getting more swing, but didn't consider it worthwhile. The vfo is stable, with no drift or warm-up miseries, so I felt it better left alone.

As a general rule, the simpler the circuitry needed to obtain the desired results, the better. So, if you will refer to Fig. 1, you can see the circuit for probably the simplest RIT a person could ever add to a rig. Simple squared! One RIT pot, two trimpots, and a switch!

First, the orange wire coming from the vfo to the LSB mode switch will need to be removed from the mode switch terminal and connected to the operating points of the DPDT switch. (One could even eliminate DPDT switch S1 if desired, since the transceive frequency can be obtained by flipping the mike switch to transmit, noting the readout frequency, then going back to receive and adjusting the RIT control to show the same frequency on the readout. Of course, then, R2, the center frequency adjustment, would not be necessary either. One could drill a hole in the front panel for the RIT pot, the control could be put in place of the VOX gain or delay pots, or it is even possible to replace the VOX delay control with a switch/potentiometer combination. This last option is probably the best method, all things considered, but the VOX delay control would then become a preset control located internally.)

The method selected for mounting the RIT control is up to the installer, of course, and there may be some other way one could mount it that would be even more practical than the one I've suggested.

(It's a shame that the boys at Heath didn't furnish RIT, but if enough people get the message that *all* the oriental dandies have RIT and everyone wants it, then maybe we'll see it come out on the next go-around.)

To adjust the two trimpots in Fig. 1, first swing the RIT pot (R3) from extreme to extreme (CW and CCW) to find the minimum and maximum frequencies. The difference between the two readings is the total swing. Then adjust the pot to mid-position. Turn S1 to OFF so that R2 can also be adjusted to the same reading. Turn to ON and, with mike gain turned completely down, press the PTT (Push-To-Talk) button on the mike and adjust R1 for the same reading on the digital readout. This completes the adjustment. The simple² RIT is now ready to go. Terminal numbers B9, B1, and B7 correspond to board-socket pins of regulator board B.

Deluxe RIT/TIT RTTY Version

At my station, radioteletype also is used. The system is by Microlog, and to be able to use the 104 on RTTY, the receiver must be adjusted to receive 1.6 kHz lower than the transmit frequency. This is because the Microlog receiver is designed to filter and regenerate everything, CW and RTTY, at the CW sidetone frequency.

I could have used the auxiliary input on the Microlog to develop the signal and maintain operation when conditions were optimum, but I would lose the filtering for the whole system. On noisy HF bands you need all the filtering you can get, and the signal conditioning designed into the Microlog is practically unbeatable.

With the new RIT circuit, I could get only 0.9 kHz swing instead of the 1.6 kHz required. So I hit upon the scheme of shifting the

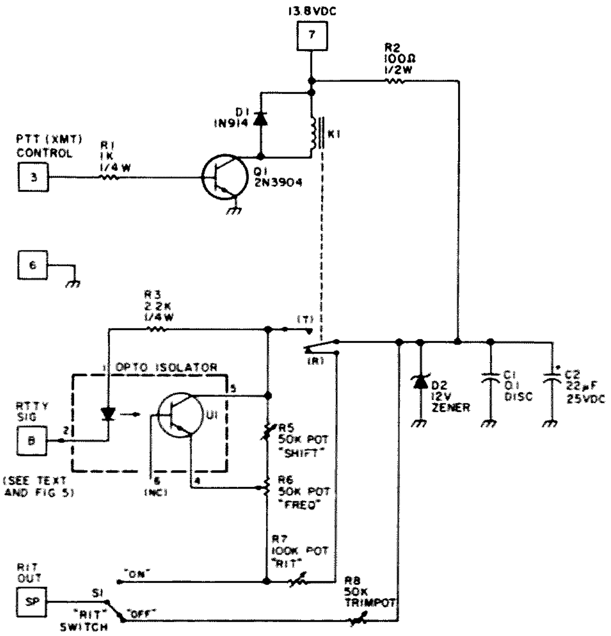

Fig. 3. Deluxe RIT circuit.

transmit frequency by a certain amount and then the receive frequency could be as much as 1.9 kHz away. With 100-Hz accuracy on the frequency readout, I would have total control over the transmit frequency as well as the receive frequency. Now I had RIT and TIT (transmitter incremental tuning).

In Fig. 2, you can see the panel layout for a little box I picked up at the local Radio Shack which is 2" high by 6" wide by 4" deep. A smaller box could have been used, but I'm glad I used this one since I ended up putting several other circuits in it, which I'll describe later.

In Fig. 3, we see the schematic for the deluxe version. It is deluxe because it has the ability to tune the transmitter and receiver incrementally and independently, and the ability to return to basic non-RIT/TIT operation. All parts in this and other circuits in this article are available at Radio Shack, and most of the parts may be substituted for by others if the ones called for aren't immediately available.

For example, the 2N3904 and 2N2222 and other transistors of similar characteristics may be substituted for each other. The 1N914, 1N4148, and 1N4001 diodes may be interchanged since they all will work effectively in the circuits. The same is true for almost all parts used. The 12-volt zener diode is the one part I haven't specified by number since almost any 12-volt zener (½ Watt) will work fine.

The trimpots may be linear or log taper, but the RIT/TIT control pots seem to work best if they are linear. The circuit is not linear across its range, but it is still pretty good except near one end of the pot's rotation. Even then, it's reasonably smooth.

The construction method I used was to mount all parts on a small piece of 100-thousandths-grid perforated board (from Radio Shack, since that's all we have here); then, pigtails from the various controls and switches were attached to the board-mounted components. There was enough strength from the leads so that no mounting problems

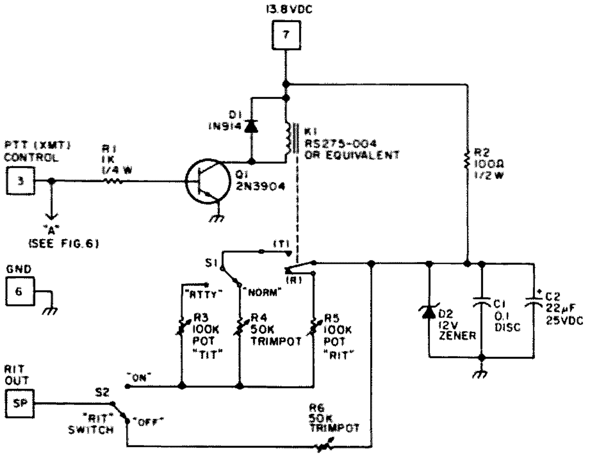

Fig. 4. RTTY circuit.

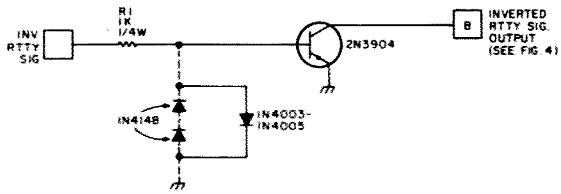

Fig. 5. RTTY flipper.

were encountered. A bit of GE's RTV (or bathroom tile silicone rubber) may be used to secure the board and relay.

The same general procedures may be used for adjusting the various pots (R3 through R6) as was described for the simple RIT circuit. First, adjust R5 (Fig. 3) for center frequency. Then turn RIT switch S2 to OFF and adjust R6 for the same frequency on readout. Turn S2 to ON and then adjust R4 with mike gain turned fully counterclockwise, mike PTT switch on, and S1 in NORMAL. Then check operation of R3 with S1 in the RTTY position. The transmit frequency should vary as indicated by the digital readout. This concludes the calibration and checkout of the circuit.

Resistor R1 in Fig. 3 is in the circuit to limit current in the transistor's base circuit. It also serves to isolate transistor Q1 from the PTT control signal line. Diode D1 keeps the inductive kickback voltage or "flyback" voltage (developed across relay K1's coil by the collapsing field when Q1 turns off) from becoming excessive and possibly "puncturing" Q1's junction, thereby ruining Q1.

Resistor R2 limits current through zener diode D2 to a safe level and allows a voltage difference between D2's 12-volt clamping effect and the 13.8-volt source. Capacitor C1 keeps the zener from generating white noise due to random current paths through the zener's junction. Capacitor C2 is cheap insurance to further guarantee that no possible drive can occur due to any residual instability during transmit.

Numbers inside terminals on the diagram refer to pin numbers of 104's accessory socket. The letters SP indicate a SPARE socket on the back of the 104. Since the deluxe version is basically an external add-on, connections must be made. Therefore, all connections are made to already existing signal and power-supply connections at the accessory socket, and the orange wire (LSB shift on vfo) is then brought out to a spare socket by routing an extension pigtail wire along the cable which runs down the center of the printed circuit board sockets underneath the 104 chassis. Use plastic ties or lacing twine of some kind to secure the wire.

Itty Bitty RTTY

While the information given up to this point is applicable to the vast majority of 104 users, there are enough RTTY freaks around (including myself) who make use of or are interested in possibly using direct RTTY modulation. I've found AFSK (audio frequency shift keying) using the generator kit offered by one of the well-known companies to be the easiest for me to put into service while avoiding any modification to the rig. But since the RIT addition was so available for experimentation, addition of some half-dozen parts to the workhorse circuit of Fig. 3 also gives direct FSK and only costs about $3.00 more.

The circuit of Fig. 4 shows how an optoisolator (Radio Shack #276-1628), a trimpot, and a fixed resistor do this. The tuning procedure is similar to the previous versions except that the shift and frequency pots may interact so that you may have to alternately adjust each pot (R5 and R6) until the desired results are obtained. The digital readout on the 104 makes this fairly easy, but a local "RTTY buddy" should be on hand to let you know how things are going on his set. Of course, it goes without saying that RTTY would be set up and used on lower sideband to be compatible with the normal use of RTTY on HF bands when one is using AFSK. But this system is normally set up and used on the air in the CW mode. Remember: Limit power during tests and operation to about 25 Watts output to save your transistors. More about this later.

The circuit shown in Fig. 4 uses a RTTY signal which normally goes to ground on "make." This is the scheme used with my Microlog keyboard, but in case your system should need the opposite (or an up-going) signal, Fig. 5 shows how another transistor and resistor may be used to get this type of operation going for you. The diodes connected from the base of the transistor to ground, in Fig. 5, may be used if your system has high-voltage switching, in which case the base-current limiting resistor also will need to be changed in value by using Ohm's law and the power law.

With the Microlog system, I was able to use a 2N2222 instead of the optoisolator, but a local friend, Lee KJ5P, told me that he had to use an optoisolator with his Model 15 to keep from getting hum on his transmitted signal. I haven't seen his circuit, but there probably isn't much difference between his circuit and this one. By the way, Lee used his 104 external vfo for the modification, and in doing this was able to avoid opening the 104 itself. The vfo is the same as the internal vfo, circuitwise, so operation still is the same. In my case, I still use AFSK but have the ability of going FSK in a few moments just by switching cables.

Word of mouth has it that the 104 can transmit at 50 Watts output by using a cooling fan on the heat sink's cooling fins (running RTTY). With four transistors good for about 70 Watts dissipation each, this may be very possible, mainly dependent upon the efficiency of the heat-exchange system. However, I've set a limit of 25 Watts output—and this is only when using a cooling fan. With the 104 on low power into a Den-Tron GLA-1000 amplifier, I

get about 65 Watts into the dummy load and this can be done all day without damage to the final transistors or driver transistors. Although protection is built in for the finals, I'd rather play it safe, and 65 Watts is enough for most purposes when you have a good antenna. In high power and very little drive, the GLA-1000 will run 150 Watts output, about the maximum safe level for the amplifier.

A spin-off of the RIT project is that I'm able to use the PTT signal in the RTTY box to key up the amplifier on low power. Heath fixed it so that the 104 may key an amplifier, but the relay keying is done only when in high power. Fig. 6 shows a relay-driver circuit with diodes to protect the transistor from any possible damage from kickback spikes from the relay. With this circuit, I can key the amplifier while on low power.

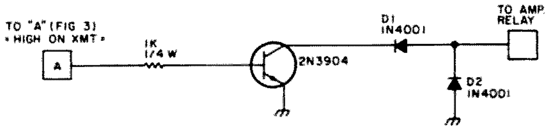

Fig. 6. Amp op.

A call to Benton Harbor gave me some additional information about RIT on the 104. While talking to one of the "supertechs," I found that an engineer there had put RIT in his 104 in some way by using the LSB shift control line to the vfo. (The technician objected, saying that the frequency shifted when changing from USB to LSB; he opined that this was somehow detrimental when changing sidebands. The fact that his boss did it and it worked was for him apparently secondary to design concepts. Perhaps this is a desirable quality in a technician!)

I was also informed that a *QST* article had a circuit for RIT on the 104 requiring one to go into the vfo. I went back into my vfo when converting my 104 to the A model, and it didn't change my opinion that it's better to leave a potential drifter alone! Unless one gets thrills from complexity, simplicity is better, permitting the operator to get it together and going without delays.

Merely taking note of the readout frequency on the 104 and tuning to it when changing sidebands puts you right back on frequency since the 104 computes everything for you. But with the recognized standard of certain sidebands being used for the different bands, when would one need to change sidebands on a particular band (except to prove that it can be done)? In normal usage, this is never done by the operator.

So now you have it. You've seen how it was done and how it can be done and perhaps this has given you some ideas for improving your system. And looking at a schematic of a 104 will show you that only three or four parts are needed in the vfo circuit to shift the frequency. If your rig doesn't have RIT, these few parts, with a little bit of thought and just a little experimentation, could give you RIT and the added versatility—even if your rig isn't a digital marvel like the 104.

Special thanks to Lee KJ5P for his initial experimentation and for proving that it could be done even before I decided to roll my own. I guess you can say we'd both rather be shifters than drifters! ■

Protect Your Pass Transistors

—the crowbar connection

After purchasing a Ten-Tec 544 transceiver and matching 262M power supply, I became concerned about the possibility of the pass transistor in the supply shorting and causing damage to the transceiver. If the transistor fails by shorting, approximately 23 volts will be applied to the transceiver.

Others concerned about shorted pass transistors in this and other brands of solid-state equipment have added crowbar SCR or transistor switches to short the output of the supply to ground if the output voltage rises to approximately 15 volts. This worthwhile scheme protects the transceiver, but it leaves one wondering what can be done to reduce the possibility of having a pass transistor fail.

It seems obvious that if the pass transistor can be made to run cooler, it is less likely to fail. Therefore, a simple method of cooling the pass transistor was sought. The instruction manual for this and other transceivers suggests fan cooling for high duty-cycle operations such as RTTY. Fans can be noisy and hard to mount. A more direct method is to reduce the amount of power that must be dissipated by the pass transistor.

Since the amount of power that must be dissipated by the transistor is the product of the current through and the voltage drop across the transistor, lowering either one of these variables would do the job. Lowering the output voltage or current is not acceptable to most operators since it results in reduced output power. The only acceptable change appears to be to reduce the input voltage to the pass transistor while still maintaining normal output current and voltage.

Measurements made on my 544 at full output power on CW on 40 meters showed that with my 120-volt ac line, the input to the pass transistor was 19 volts at a load current of 13 Amperes. Under these conditions, the transistor is dissipating 68 Watts of power. I then connected the ac input of the 262M power supply to a variable ac source, and tests were run to determine how low the nominal 115-volt input could be made while still maintaining excellent voltage regulation at the required current of 13 Amperes.

I found that for my supply, the input could be lowered to 102 volts with only a 0.09-volt reduction in the output voltage! Under these conditions, the pass transistor was only dissipating 28 Watts, a reduction of 40 Watts or 59% over the operation at the full 120-volt condition! Of course, the transistor runs much cooler under these conditions and is less likely to fail. The results of these tests are shown in Table 1.

To take full advantage of this information, one could connect the input of the supply to a continuously adjustable ac voltage source rated at 3 Amperes (for the 544/262M) and reduce the ac voltage until the nominal 13.8-volt output just starts to drop from its no-load value when the transmitter is keyed at full output power.

The "output" pilot lamp on the 262M supply will flicker when this point is reached. Unfortunately, continuously variable ac voltage sources such as Variac or Powerstat autotransformers are expensive and not always readily available, so a different method is used.

As shown in the schematic diagram in Fig. 2, a low-voltage filament transform-

Input, volts ac	Input to pass transistor, volts dc	Output of power supply, volts dc	Power dissipated by pass transistor (Watts)	Power saved over 120-V input condition
120	19	13.76	68	Original
112	17.9	13.76	54	14 W = 20%
108	16.9	13.76	40	28 W = 41%
102	15.8	13.67	28	40 W = 59%
95	14.03	12.72	17	51 W = 75%

Table 1. Pass-transistor dissipation and output voltage vs. ac input voltage for the Ten-Tec 262M power supply. Notes: 1. Load current was 13 Amperes as indicated on Ten-Tec ammeter. 2. All voltages measured with a Fluke 8022 DVM. 3. 95-volt input arbitrarily deemed not an acceptable operating condition. 4. Ac input current to power supply at 120 Vac was 2.5 Amperes. 5. Ac voltages measured at pins on power-supply line cord plug.

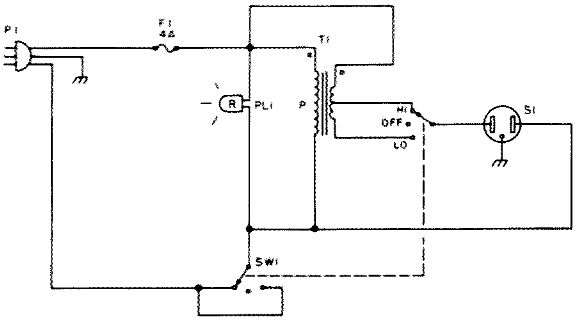

Fig. 1. Schematic of the pass transistor saver. SW1—DPDT toggle switch with center off position; S1—120-volt chassis-mount receptable; T1—Filament transformer, 117/12.6 V c-t at 3 A (Stancor P-8358 or equivalent, see text).

er is connected in a manner that allows approximately 6.3 or 12.6 volts to be subtracted from the normal supply voltage. At low loads, such as 13 Amperes, the switch is placed in the Low position to subtract 12.6 volts from the ac supply line. At greater load currents, such as 16 Amperes, the switch is placed in the High position to subtract 6.3 volts from the ac supply line.

Table 2 shows the results of tests made when operating the 544 using the filament transformer. When operating at full output power on 40-meter CW, my pass transistor is now dissipating only 26 Watts, a savings of 42 Watts or 62% over full 120-volt line voltage operation. My pass transistor heat sink is now cooler than the heat sink on the transmitter's final output transistors after a full evening's operation.

Since more than 13 Amperes may be required for full output power on other bands, a test was conducted at a load current of 16 Amperes using a filament transformer. The results of this test also appear in Table 2, and show that at least a 40% savings in power dissipation can be realized while still maintaining excellent voltage regulation.

Construction and parts layout is not critical. The unit was constructed on a 2" × 4" × 5" chassis. Proper phasing of the transformer windings is accomplished by the cut-and-try method. If your trial connection causes an increase in output voltage, reverse the secondary leads of the transformer. For safety, make these tests with the transceiver disconnected from the unit. Purists may want to install an additional 1/2-Amp fuse directly in series with the primary of the transformer.

If the normal line voltage at your location is significantly less than 120 volts, such as 110 volts, a 10-volt c-t transformer or even a 6.3-volt c-t transformer may be more suitable than the 12.6-volt unit specified. When selecting a transformer, keep in mind that the output voltage of a filament transformer varies as its load current varies. The output voltage of a transformer rated at, say, 12.6 V at 5 Amps will be more than 12.6 V at currents less than 5 Amps assuming rated primary voltage. Two or more transformers with the secondaries connected in series could be used with a multiple-position selector switch to give a greater number of combinations.

Equipment manufacturers must design their supplies to operate over a wide range of input voltages. If the voltage at your location is on the high end of the scale, or even in the middle, this unit will allow your power supply pass transistor to run cooler while still maintaining good voltage regulation and maximum transmitter output power. This, combined with a crowbar, will reduce the chances of damage to your transceiver and may save you the trouble of locating and replacing a defective pass transistor.■

Switch position	Load current (Amps)	Input to pass transistor, volts dc	Output of power supply, volts dc	Power dissipated by pass transistor (Watts)	Power saved over 120-V input condition	Ac input to power supply, volts
Note 3	13	19.1	13.88	68	Original	120
Low	13	15.8	13.82	26	42 W = 62%	103.7
High	13	17.4	13.88	46	22 W = 32%	112.0
Note 3	16	18.0	13.88	66	Original	120
Low	16	14.7	13.20	24	42 W = 63%	Note 4
High	16	16.3	13.82	40	26 W = 40%	Note 4

Table 2. Results when operating the power supply from the transformer voltage-reducing unit. Notes: 1. A slight flicker could be seen on the 262M power-supply Output light in the Low, 16-Amp condition. 2. These tests were run one week after the tests shown in Table 1. Note that normal output voltage is slightly (0.12 V) higher. 3. None-across-the-line operation for reference. 4. Not measured. 5. Normal line voltage was approximately 120 volts.

All Tied Up in Knots?

—the twisted tale of Thomas J. O'Harra

Glenn Jacobs KC7M
Poverty Flat AZ 85925

My grandfather was Nazario Garcia Baca, and he was the very first radio amateur in all New Mexico. He was also a sheep rancher, and that brings up the most famous knot of all, the "sheepshank." But the sheepshank has nothing whatever to do with sheep, and Grandfather Baca never used one and you will never need one either, so skip it.

The Bowline

My other grandfather, Frank Elmer Jacobs, told me a story about another kind of knot, done on a ham—a ham actor, that is. It seems the good old boys in San Angelo (Texas) wanted to form a vigilante committee like the ones in San Francisco to get rid of a certain Thomas J. O'Harra, alias "Pretty Good Actor." (He had been legally acquitted three times in a row of swindling women by promising to marry them.) The committee had posters printed up, inviting Pretty Good Actor to a pretty good "necktie party."

Well, Pretty Good Actor was hard to bluff, and he was doing a couple of lucrative productions at the time, so he stayed. There was nothing to do but go ahead and hang the man for the glory of Texas and the honor of Texas women. The committee caught him coming out of play practice the very next night. They wanted to hang the man, but not kill him. Instead of the traditional "hangman's knot," they used a "bowline knot." It makes a noose that will not tighten up. By including Pretty's chin in an oversized noose and running the hanging rope up

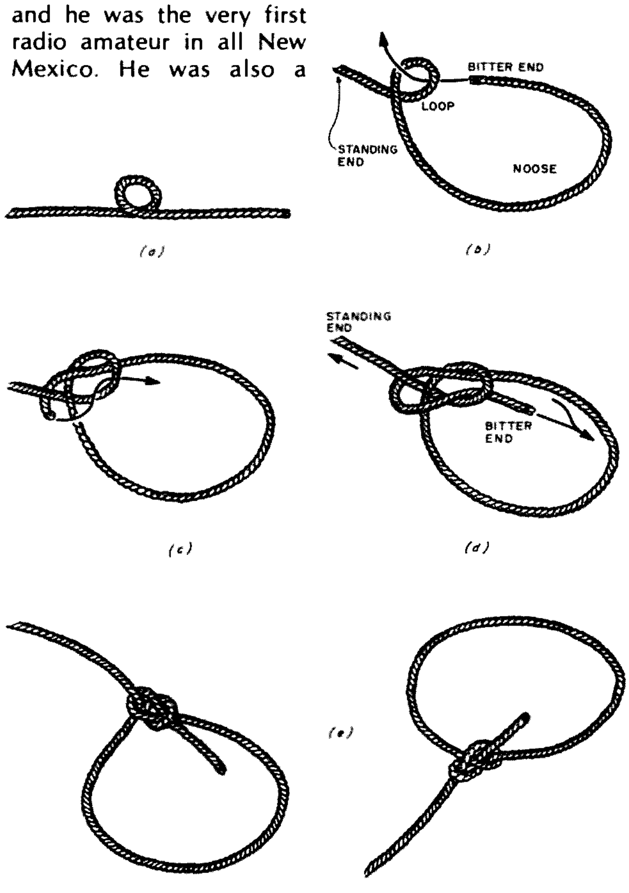

Fig. 1. The bowline. (a) Leave plenty of rope for both the noose and the knot, then form a loop. (b) Pass the bitter end through the loop as if you were tying a simple overhand knot. (c) Now take the bitter end around the standing end and back through the loop. (d) This is a bowline knot. All it needs is tightening in a special way. Notice that the bitter end has merely been folded back on itself. To tighten the bowline, pull the standing end while holding both the bitter end and the other rope that comes out of the same hole. Beware: If you pull it wrong, the knot will "turn inside out" and leave you with a useless slip knot around the bitter end. (e) The front and back of the tightened, finished bowline knot.

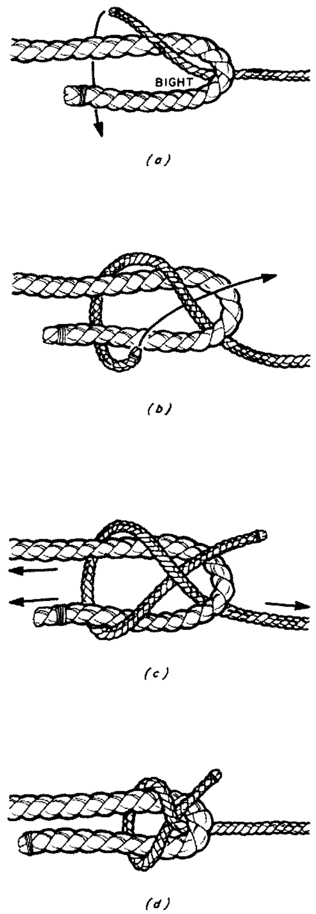

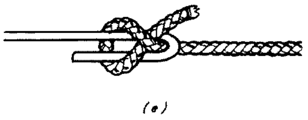

Fig. 2. The sheet-bend. (a) First, bend the stiffer of the two ropes back on itself and stick the floppier rope through the bight. (b) Wrap the light rope around the bight of the heavy one. (c) Weave the light rope over the heavy, under itself, then back over the big one. Tighten the sheet-bend carefully by pulling both parts of the big rope one way and the standing end of the smaller rope the other way. By the way, this knot is also good to join two ropes of the same size. (d) The finished sheet-bend. (Note: This knot is easy to untie.) (e) "Copperweld™-bend" for tying a rope onto stiff antenna wire. The wire is stiffer than the rope, even though it is thinner, so the wire takes the bend and the thicker rope makes the knot.

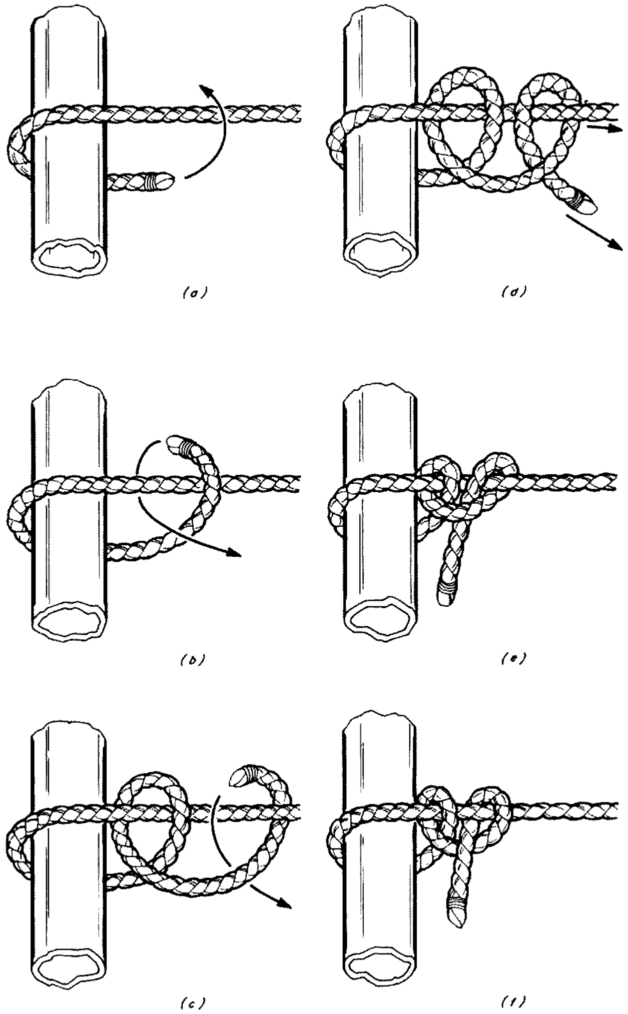

Fig. 3. The double-half-hitch. (a) Wrap the bitter end around the tower leg. (b) Wrap the bitter end around the standing end and poke it through the loop to form the first half-hitch. (c) Now do it again in the other direction to form the other half-hitch. (Note: If you make both half-hitches in the same direction, you get a clove-hitch instead. Either one works just fine.) (d) Just right. Now tighten it by pulling on the bitter end. If the standing cord is not under tension, pull on it, too. (e) The finished double-half-hitch. This can be tied in a rope with a wild horse (or a 160-meter dipole) pulling on the other end. (f) The clove-hitch. It is every bit as good.

beside his nose instead of behind the ear, it did not cut off his air nor the circulation to his head.

The victim swung back and forth and slowly twisted in the night breezes, looking up the rope. The vigilante committee marched away then hid behind a fence and watched, barely able to keep from bursting out laughing. When Pretty Good Actor was convinced they were gone, he fished a knife out of his boot and cut himself down and was never seen again in San Angelo.

Today when I hung up my dipole on the flagpole, I used a bowline for the same reason. I wanted a loop that would not tighten. Also, a bowline is easier to untie than a lot of other knots. See Fig. 1.

The Sheet-Bend

The very useful "sheet-bend" got its present name in the British Navy over three hundred years ago. "Tie onto that big cable," the captain ordered. "Tie it?!" protested the gunner's assistant. "Sir, I can barely bend it." The old name of the sheet-bend was [illegible].

The sheet-bend is really the same knot as the bowline. If you tie two ropes together with a bowline, it is called a sheet-bend. It is particularly useful for tying a little rope to a big one. I used a sheet-bend on each end of my dipole today to attach the nylon ropes to hold it up. You and I might privately call that a "copperweld™-bend," but the sailors and scouts wouldn't recognize it by that name. See Fig. 2.

The Double-Half-Hitch

Why didn't they call this one a "whole-hitch," or just a "hitch"? Anyway, I used it this afternoon to tie the northwest end of my skywire to a tower leg. It is good for that sort of thing, because you can tie it while you are pulling on the rope. See Fig. 3.

The Packer's Hitch

Say you want to pack that triband beam and haul it up the mountain on Field Day. You get it all up on the rack of your cousin-in-law's plumbing truck. Then what? How do you tie it? Just wrap all the rope you own around it? Keep watching in the rear-view mirror for one of those slippery elements to fall out on the road behind you? Fig. 4 shows a little rope-trick that will really hold things together.

Summary

Just any old knot might fail you in a pinch. The bowline will make a noose that will not tighten up. Its cousin, the sheet-band, is good for tying ropes together, even if they are different

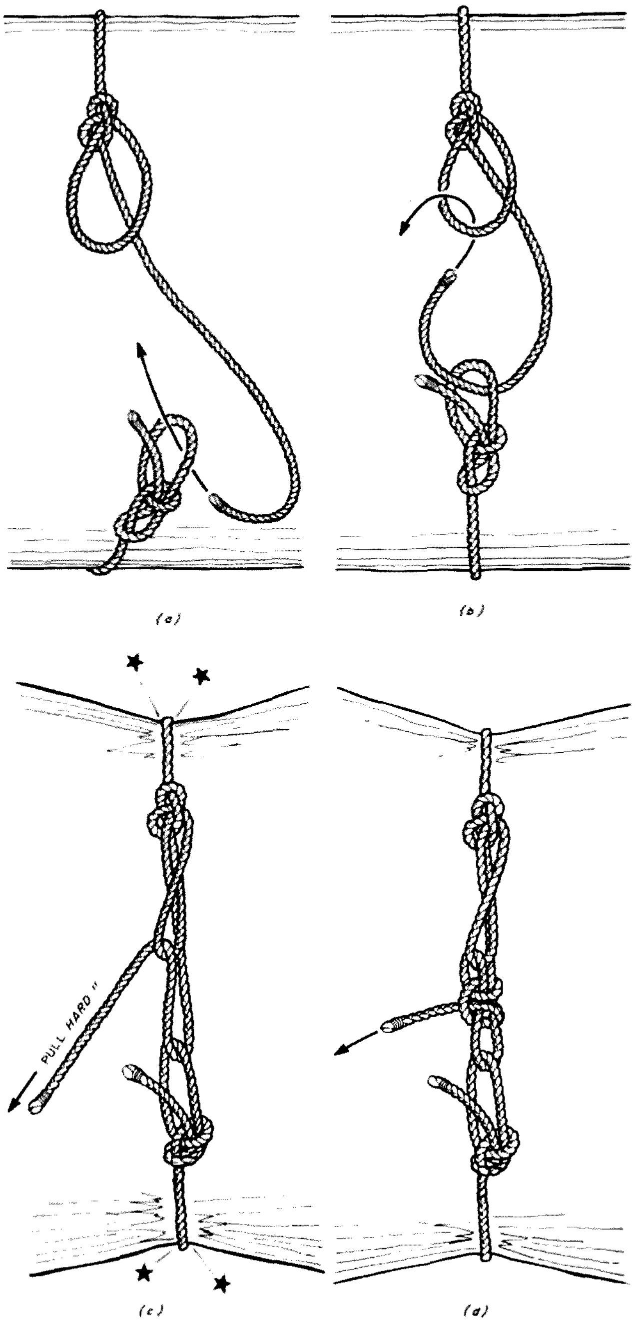

Fig. 4. The packer's hitch. (a) Wrap the rope around your load. Make a bowline at one end of the rope. Make another bowline near the other. Leave plenty of loose rope at the bitter end. (b) Loop the bitter end through both bowlines and pull down hard. (c) Now pull down harder! More! You have a three-to-one mechanical advantage now. Sock it to it! Str-r-e-e-t-ch that rope! (d) Now tie the bitter end around below the bowline with a double-half-hitch.

sizes. The double-half-hitch can be tied on a rope under tension. And the packer's hitch (which is a combination of the bowline and double-half-hitch) will let you put the squeeze on anything you can get a rope around. These special knots are good for passing the Boy Scout Tenderfoot exam and are good for many, many jobs in the Amateur Radio Service.■

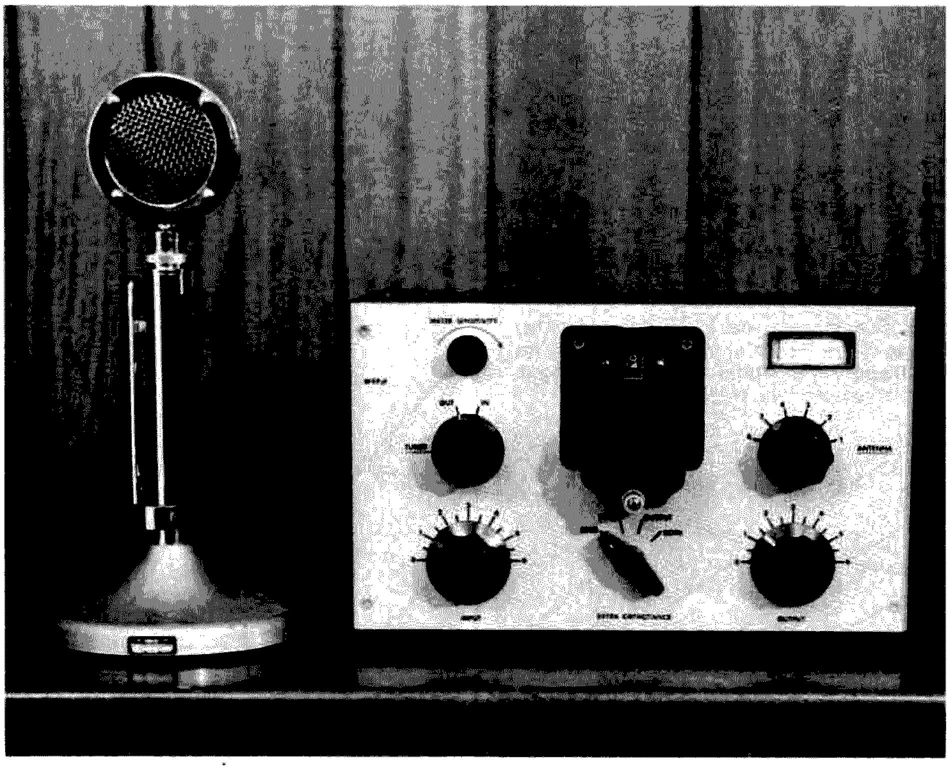
The Coax Matcher

—it may be all the tuner you need

Antenna tuners can be designed to match a wide range of feedline impedances to the low-output impedance of the typical amateur transmitter. Many of the current, commercially-made tuners can be used for coaxial feedlines or for the high-impedance open-wire feedlines. This flexibility of use is not without its price, however, as the high-impedance capability requires the use of wide-spaced, high-voltage capacitors. These capacitors are characterized by their scarcity, large size, and high cost.

If the tuner could be limited to use with low-impedance coaxial feedlines from normal antennas, then a network could be built using tuning capacitors of the closer-spaced variety similar to the loading capacitors in today's linear amplifiers. Fig. 1 is a schematic of such a "coaxial tuner" that I built and use with my HF antennas, which include a tribander for 20, 15, and 10, a quarter-wave vertical for 40, and an inverted vee for 80 meters. My ham gear is the old vacuum-tube type with transmitter input powers of 1200 Watts PEP on sideband and up to 1 kW on CW and RTTY. With the exceptions of the 75-meter phone band and the upper portion of 10 meters, I have no trouble loading the rig with the existing swr's and with no line tuner in use.

I wanted a tuner because I planned to acquire a solid-state transceiver in the near future. Discussions with others about the swr sensitivities of the newer solid-state rigs had made me revise my former negative attitude towards coax tuners or line matchers. A tuner is



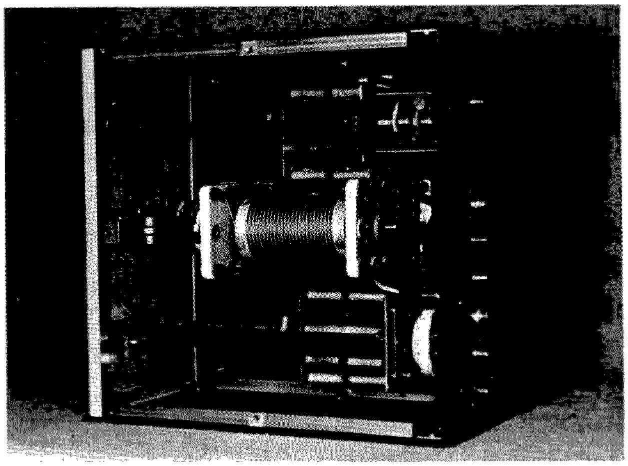
Tuner, with D-104 for size comparison.

certainly a much simpler way of making a solid-state rig happy than trying to find an antenna that presents a constant 52-Ohm load from one end of the band to the other. The coax losses are not decreased, or increased, but the desk may have to be rearranged to accommodate the tuner.

When using the tuner on 75 meters, the 1200-pF variable capacitors did not have enough total capacity, so switch S2 and capacitors C3 and C4 were used to provide an additional 500 pF on the input, on the output, or on both when needed. The in/out switch, S1, is used to remove the tuner from the circuit for those portions of the band where the swr is a reasonable figure. The antenna switch, S3, merely selects the coaxial line of your choice. I use one of the output connectors to feed my dummy load and find this convenient for tune-ups or tests. The rf level meter is to ensure that the tuner is set for maximum output rather than to a false resonance.

The leads connecting the inductor and the variable capacitors should be as short in length and as large in cross-section as you can manage. With my prototype breadboard unit, I could not obtain an swr of 1 to 1 on frequencies above 29.2 MHz and found that, while the inductor had reached its minimum value, I still needed less inductance. Changing from number 14 wire to 3/8" copper strap decreased the lead inductance and cured the problem. Purists may question the open-type switch used to select the various antenna connectors, but the swr meter shows no serious effects. If any undesirable swr effects did occur, they could be corrected by the tuner.

An swr meter should be connected between the transmitter and the tuner so that the tuner can be adjusted properly. This is also the correct place for the power meter since swr's greater than 1 to 1 can give some very odd power readings. Initial tuning adjustments should be made at the lowest power level needed for your particular swr meter. The amount of inductance and capacitance needed will vary from band to band and will depend upon the swr of each antenna, the length of the feedline, and whether you are operating above or below the resonant frequency of the antenna. Initial adjustments may get to be a bit tiresome, so the settings should be logged for future use.



Inside view of tuner.

I recommend that a systematic approach be used in tuning the network as the adjustments are somewhat interactive and a helter-skelter knob-twister could get a bit frustrated. For initial adjustments on any frequency of interest, I first set the inductance so that one turn was in use. Then I varied both the input and output capacitors to find their effect upon the swr. If the swr was still high, I put another turn of the inductor in the circuit and again readjusted the capacitors, looking for a decrease in swr. This process was continued until the desired 1 to 1 swr was obtained.

Fig. 2 is a chart showing the approximate settings I obtained at various frequencies. The feedlines to the beam and to the inverted vee are about 150 feet long. The line to the vertical is about 50 feet long. Swr measurements were taken with a Heathkit HM-102 swr/wattmeter.

The in/out switch and the antenna switch are mounted on aluminum plates which are parallel to and spaced about 2½" from the rear panel. This permitted the wiring of these switches and the antenna connectors prior to final assembly. It did require the use of rather long ¼" shafts to reach the front panel. The small RG-8/M mini-foam coaxial cable from Radio Shack makes the wiring easier than it would be with normal size RG-8/U.

For the wiring between the antenna switch and the coaxial connectors, I used direct, unshielded wire where the switch and connectors were so close that coax would have been awkward or nearly impossible to use. The coaxial con-

Parts List

C1, C2	2-gang broadcast receiver-type capacitors, 600 pF per gang
C3, C4	500-pF ceramic or mica transmitting capacitors (high voltage)
C5, C6	.005-uF, 200-V disc
R1	39k, ½ W
R2	4.7k, ½ W
R3	25k pot
L	15-uH variable inductor
D1	1N34A germanium diode
M1	0-1 milliammeter
S1	DPDT ceramic wafer switch, two section
S2	DP4-position ceramic wafer switch, two section
S3	SP multiple position, to match number of connections required

Cabinet pictured—Moduline 7-12-12

nectors are mounted in a straight line across the rear panel. A much better arrangement would be to mount them in a circle so that very short direct leads could be used between the antenna switch and the respective connectors.

The rf voltmeter voltage-divider/rectifier components are mounted on a terminal strip near the in/out switch since this was a convenient location to sample the rf voltage. The B & W #3852 inductor has a total of 24 turns of wire and its inductance of 15 uH is more than is needed. Ones with maximum inductances of 7-10 uH would probably do as well and would probably be much smaller physically.

Parts procurement is always a problem for the builder, even for simple projects like this tuner. Surplus dealers are likely to have suitable variable capacitors, switches or switch sections, and perhaps variable inductors. Exact duplicates are not necessary. Capacitors with 4 gangs each and totalling about 1800 pF would be great as they would allow the elimination of C3 and C4 along with switch S2. A tapped coil could be used instead of the rotary coil. If so, I recommend a tap each half turn at the low-inductance end of the coil for about 4 taps or so, as the 10-meter inductance values may be quite small and a change of a whole turn at a time may miss the best spot. Better yet would be to make the last tap experimentally after assembly and near any problem frequency encountered. Cabinets are now rather expensive items, so home-brew or surplus ones may be a good choice. Many turns-counting dials are available commercially. The one pictured is an old surplus B & W #11282 of ancient vintage.

I used light grey spray paint on the front panel and identified the controls with press-on lettering. A few light coats of clear plastic spray paint were then applied to protect the finish. Switches S1 and S2 were assembled from ceramic wafers from my junk box and I used two wafers each to provide some isolation between sections. Switch S3 is a husky switch from a surplus BC-375 antenna-tuning unit. The knobs were also resurrected from my junk-box assortment.

A final word of caution: This coaxial tuner is not designed for wide variations in load impedance. If you have a shorted trap in your tribander beam and an swr of 10 to 1, this tuner will not correct your problem. It is not suitable for use with open-wire line. High-load impedances *cannot* be matched without developing high voltages across the capacitors with consequent arcing and damage. The tuner is capable of tuning out the reactance of coaxial cables feeding normal, resonant antennas and can present an apparent swr of 1 to 1 to the rig.■

Ant Resonance MHz (swr)	Test Freq MHz	Swr without tuner	Tuner Values for 1:1 Swr: Input C pF	Inductance (# turns used)	Output C pF
3.66	3.505	3++:1	600	5T	940 + 500 FIXED
(1.3:1)	3.950	3++:1	800 + 500 FIXED	3.8T	1080
7.20	7.005	1.4:1	800	4.3T	740
(1.1:1)	7.295	1.2:1	740	4.3T	720
14.10	14.005	1.8:1	680	2T	620

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

CORNWALL NY
OCT 2

The Orange County ARC will hold its annual auction on Saturday, October 2, 1982, from 10:30 am to 2:30 pm, at Munger Cottage, Cornwall NY. Sellers will be admitted at 9:00 am. Admission is $1.00. Talk-in on 146.52. For further information, call Bill N2CF at (914)-928-6288.

SYRACUSE NY
OCT 2

The Radio Amateurs of Greater Syracuse (RAGS) will hold their annual hamfest on Saturday, October 2, 1982, from 9:00 am to 6:00 pm at the Art and Home Center, New York State Fairgrounds, Syracuse NY. There will be commercial exhibitors and a large indoor flea market. Breakfast and lunch will be served. Door prizes, tech talks, a program on DXpeditions, women's activities, entertainment, and various contests will be featured. Admission is $3.00 and indoor flea-market space will also be available. Talk-in on .90/.30 and .31/.91.

ANNISTON AL
OCT 2-3

The Calhoun County Amateur Radio Association will hold its 3rd annual Anniston Hamfest on Saturday and Sunday, October 2-3, 1982, at the City Auditorium, Anniston AL. On Saturday, doors will be open from 9:00 am to 5:00 pm; on Sunday, from 9:00 am to 2:00 pm. Exhibitors may begin setting up at 7:00 am both days. Admission is free, as well as coffee, bingo, and parking for self-contained RVs. The FCC will administer exams. Talk-in on 147.69/.09 and 146.10/.70. For more information and reservations, contact Dale Boothe KA4LRL, 3430 Greenwood Avenue, Anniston AL 36201.

BOXBORO MA
OCT 2-3

The Federation of Eastern Massachusetts Amateur Radio Associations will hold the New England ARRL Convention on October 2-3, 1982, at the Sheraton Boxboro Hotel, Route 495 at Route 111, Boxboro MA. On Saturday the hours will be 9:00 am to 5:00 pm and on Sunday, 10:00 am to 5:00 pm. Early-bird registration is $4.00. The Saturday evening banquet, dance, and show is $13.50. Features will include a Wouff Hong midnight ceremony Saturday and YL programs on both days. For reservations and advance registration, send an SASE to Arthur Tomkinson W1THT, 9 Oliver Terrace, Revere MA 02151 and make checks payable to FEMARA.

WARRINGTON PA
OCT 2-3

The Pack Rats sixth annual Mid-Atlantic VHF Conference will be held on Saturday, October 2, at the Warrington Motor Lodge, Rte. 611, Warrington, PA. Advance registration $3.00; at the door, $4.00. Price includes admission to the 11th annual Pack Rats Hamarama on Sunday, October 3, at the Bucks County Drive-In Theater, Rte. 611, Warrington, PA. Admission to the flea market $2.00 and tailgating $4.00 per space. Bring your own table. Gates open at 7:30 am. Talk-in via W3CCX on 146.52. Information for both events is available from Hamarama '82, POB 311, Southampton PA 18966 or Lee A. Cohen K3MXM at (215)-635-4942.

ROCK HILL SC
OCT 3

The York County Amateur Radio Society will hold its 31st annual hamfest on Sunday, October 3, 1982, at Joslin Park, Rock Hill SC, starting at 0700. Pre-registration is $3.00; at the gate, $4.00. There will be prizes. Talk-in on 146.43/147.03 and 146.52. For additional information, contact YCARS, Box 4141 CRS, Rock Hill SC 29730.

YONKERS NY
OCT 3

The Yonkers Amateur Radio Club will hold its electronics fair and flea market on Sunday, October 3, 1982, from 9:00 am to 5:00 pm, rain or shine, at Yonkers Municipal Parking Garage, corner of Nepperhan Avenue and New Main Street. Admission is $2.00 each; children under 12 will be admitted free. Sellers' spaces are $6.00 (bring your own table) and include one admittance. Gates will be open to sellers at 8:00 am. There will be live demonstrations, hourly prizes, an auction, free parking, refreshments, and unlimited free coffee all day. Talk-in on 146.265/146.853, .52, or CB channel 4. For further information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

SAN ANGELO TX
OCT 3

The San Angelo Amateur Radio Club will hold its annual swapfest on Sunday, October 3, 1982, starting at 8:00 am, at the clubhouse adjacent to Mathis Field, San Angelo TX. Pre-registration tickets are $4.00 and tickets at the door are $5.00. There will be a bar-b-que served on the grounds and door prizes. Talk-in on .34/.94. For more information, contact Mark Haskell, Rte. 3, Box 92, San Angelo TX 76903.

ROME GA
OCT 3

The 1982 Rome Hamfest will be held on Sunday, October 3, 1982, from 9:00 am to 4:00 pm, at a new location, the Rome Civic Center, Turner McCall Boulevard (US 27 and GA 20), Rome GA. Features will include a barbecue and ladies' prizes. Talk-in on 147.90/.30. For more information, contact Buddy Waller NO4U, 18 London Lane, SE, Rome GA 30161.

GRAND LEDGE MI
OCT 3

The Central Michigan Amateur Radio Club will hold Ham-Fair '82 on October 3, 1982, starting at 8:00 am, at the Grand Ledge High School, Grand Ledge MI (7 miles west of Lansing). Registration for adults is $2.50. Tables are 75¢ per foot. There will be ham gear, accessories, computers, electronic equipment for the home, prizes, demonstrations, a swap shop, a cafeteria, and parking. Talk-in on .34/.94 and .52. For more information, write Ham-Fair '82, PO Box 10073, Lansing MI 48910, or call (517)-626-2237.

MT PROSPECT IL
OCT 3

The Mt. Prospect Amateur Radio Club and Cook County ALERT will hold RA-COM '82 on October 3, 1982, at Prospect High School, 801 W. Kensington, Mt. Prospect IL. Advance tickets are $1.50 and tickets at the door are $2.00. Doors will open at 8:00 am. There will be a large indoor electronics flea-market area, commercial exhibits, seminars, door prizes, and more. Talk-in on 146.52. For more information or reservation forms for flea-market or commercial booths, send an SASE to RA-COM, PO Box 89, Mt. Prospect IL 60056.

SANTA CRUZ CA
OCT 8-10

The Santa Cruz County Amateur Radio Club will host the 1982 Pacific Division Convention on October 8-10, 1982, at the Holiday Inn, 611 Ocean Street, Santa Cruz CA. Full registration is $25.00 and includes the Sunday banquet, the ladies' program with lunch, all Friday evening events, and all forums and technical talks. Registration for forums and talks only is $7.00. Booths are $100. Friday evening events include exhibits, a league session, and a hospitality room. For more information, please write SCCARC Convention, PO Box 238, Santa Cruz CA 95061, or phone (408)-426-6691.

ASHEVILLE NC
OCT 9

The Western North Carolina Amateur Radio Society will hold its seventh annual Autumnfest on October 9, 1982, at the Asheville Civic Center, Asheville NC. Admission is $3.00 in advance and $4.00 at the door. Flea market tables will be $5.00 at the door. Activities (all indoors) will include the McElray Memorial CW Competition, bingo for the ladies, and dealer and flea market tables. Travel, motor home, and camping facilities will be available. Talk-in on .31/.91, .16/.76, and .52. For more information, contact WCARS, PO Box 1488, Asheville NC 28802.

PARK RAPIDS MN
OCT 9

The Headwaters Amateur Radio Club will hold a hamfest on October 9, 1982, from 9:00 am to 5:00 pm, in the Middle School Gym, Park Rapids MN. Admission is $2.00, display tables are $3.00 each, and commercial companies are $5.00 each. Refreshments and prizes will be available. Talk-in on 147.300 and 147.900.

MEMPHIS TN
OCT 9-10

The Memphis Hamfest will be held on October 9-10, 1982, in the Mid South Building at the Memphis Fairgrounds, Memphis TN. Children under 14 will be admitted free. The hours will be from 8:00 am to 4:00 pm on Saturday and 8:00 am to 2:00 pm on Sunday. The deadline for flea-market and dealer setups is 9:00 pm on Friday. Activities will include forums, ladies' programs, and a Saturday night hospitality party. There will be on-site trailer hookups available. Talk-in on .28/.88 and .25/.85.

Subscription Problem?

73 Magazine does not keep subscription records on the premises, therefore calling us only adds time and doesn't solve the problem.

Please send a description of the problem and your most recent address label to:

73 Magazine

Thank you and enjoy your subscription.

PRESERVE 73 MAGAZINE BINDERS & FILE CASES

Keep your issues of 73 Magazine together, handy and protected in handsome and durable library files or binders. Both styles bound in red leatherette with the magazine logo stamped in gold.

Files: Each file holds 12 issues, spines visible for easy reference. $5.95 each, 3 for $17.00, 6 for $30.00

Binders: Each binder holds 12 issues and opens flat for easy reading. $7.50 each, 3 for $21.75, 6 for $42.00

(Postage paid in USA. Foreign orders include $2.50 per item)

Please state years: 1977 to 1983

Send check or money order to:
JESSE JONES BOX CORP.
P.O. Box 5120
Philadelphia, PA 19141
Allow 4 to 6 weeks for delivery

For more information, contact Clayton Elam K4FZJ, 28 N. Cooper, Memphis TN 38104, or phone (901)-274-4418 (days) or (901)-743-6714 (nights).

VIRGINIA BEACH VA
OCT 9-10

The ARRL Virginia State Convention and Tidewater Computer Show-Hamfest-Electronic Flea Market will be held on Saturday and Sunday, October 9-10, 1982, from 9:00 am to 5:00 pm both days, at the pavilion in Virginia Beach VA. Admission is $3.50 for both days. Flea-market tables are $5.00 for one day or $8.00 for both days; commercial flea-market tables are $15.00 for both days, and commercial booths are $30.00 for both days. Featured will be dealers, special displays, forums, computers, satellite equipment, special XYL programs, and a cocktail party Saturday night. There will be an advance ticket drawing for a hand-held transceiver, as well as many valuable door prizes. For more information and/or tickets, contact Jim Harrison N4NV, 1234 Little Bay Avenue, Norfolk VA 23503, or phone (804)-587-1695.

BEDFORD IN
OCT 10

The Hoosier Hills Ham Club will hold its 21st annual Hoosier Hills Hamfest on Sunday, October 10, 1982, at the Lawrence County 4-H Fairgrounds, 4 miles southwest on US Highway 50, Bedford IN. Registration is $3.00 per person and the swap shop is $2.00 (bring your own tables). The gate will open at 10:00 am on Saturday, October 9th, for campers and flea market setups (registration required). There will be a free fish fry, campfire, entertainment, coffee, and overnight camping on Saturday night. Features will include prizes, ladies' free bingo, and food served at the hamfest all day Sunday. Talk-in on 146.13/.73. For further information, contact Dick Reistter KA9JTZ, Secretary, Hoosier Hills Ham Club, Box 891, Bedford IN 47421.

PARAMUS NJ
OCT 10

The Bergen ARA will hold a ham swap 'n sell on October 10, 1982, from 8:00 am to 4:00 pm, at Bergen Community College, 400 Paramus Road, Paramus NJ. Buyers will be admitted free and sellers will be charged $3.00. There will be tailgating only; bring your own table. Thousands of spaces will be available. Talk-in on .79/.19 and .52. For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

LIMA OH
OCT 10

The Northwest Ohio Amateur Radio Club will hold its sixth annual hamfest on Sunday, October 10, 1982, at the Allen County Fairgrounds, Lima OH. Indoor flea market tables will be available for $5.00 for an 8-foot table or $3.00 for half a table. Tickets are $2.50 in advance, $3.00 at the door. Doors will open at 6:00 am and grand prizes will be drawn at 3:00 pm. Overnight camping will be available at the fairgrounds. Talk-in on .07/.67, .63/.03, .34/.94, and .52/.52. For more information, write NOARC, Box 211, Lima OH 45802.

BALTIMORE MD
OCT 10

The Columbia Amateur Radio Association will hold its 6th annual hamfest on Sunday, October 10, 1982, from 8:00 am to 3:30 pm, at the Howard County Fairgrounds (15 miles west of Baltimore, just off I-70 on Rt. 144, 1 mile west of Rt. 32). Admission is $3.00, tables are $6.00, tailgating is $3.00, and indoor tailgating is $5.00. Food will be available and prizes will be awarded. Talk-in on 147.735/.135 and 146.52/.52. For table reservations or information, write Sue Crawford, 6880 Mink Hollow Road, Highland MD 20777, or phone (301)-286-3805.

WAUKESHA WI
OCT 10

The Kettle Moraine Radio Amateur Club will hold its annual Ham, Computer, Video Fest on Sunday, October 10, 1982, at the Waukesha County Expo Center, Highways F and FT, Waukesha WI. Tickets are $2.00 in advance and $3.00 at the door. Tables are $3.00 for each 4-foot length; reservations will be accepted until October 1, 1982. Since all facilities will be indoors, the hamfest will be open rain or shine, beginning at 8:00 am. There will be prizes, food, commercial exhibitors, a "happy hour," and free parking. For table reservations, send a check payable to KMRA Club, PO Box 411, Waukesha WI 53187.

NEW ORLEANS LA
OCT 16-17

The New Orleans hamfest-computerfest, Amacom '82, will be held on October 16-17, 1982, at a new location, Delgado Community College, near City Park, New Orleans LA. Admission is $3.00 per person over 12 years old. There will be exhibitors, a flea market, forums, ladies' activities, prizes, and a discussion on international broadcasting by the owner of the nation's only commercial shortwave radio station. Amateur radio tests will be given Saturday morning by the FCC. Talk-in on 147.285/.885 and 449.0/444.0. For more information, and reservations for FCC tests, write W. D. "Bill" Bushnell WA5MJM, Amacom Chairman, c/o Jefferson Amateur Radio Club, PO Box 73665, Metairie LA 70033, or phone (504)-887-5022.

ANDERSON IN
OCT 17

The Madison County Amateur Radio Club of Anderson IN will have a hidden transmitter hunt on October 17, 1982. The starting point will be the Mounds State Park near Anderson. Prizes will be awarded. For more information, contact Frank Dick WA9JWL, 921 Isabelle Drive, Anderson IN 46013, or phone (317)-642-1237.

CHICAGO IL
OCT 17

The Chicago Citizens Radio League will hold its first annual hamfest on October 17, 1982, at the North Shore American Legion Post, 6040 N. Clark, Chicago IL from 7:00 am to 4:00 pm. Due to limited table space, table reservations must be made in writing to Fred Marlette KA9FUO 1851 W. Chase, Chicago IL 60626.

CHELSEA MA
OCT 17

The 19-79 Repeater Association of Chelsea MA will hold its annual flea market on Sunday, October 17, 1982, from 11:00 am to 4:00 pm (sellers admitted at 10:00 am), at the Beachmont VFW Post, 150 Bennington Street, Revere MA. Admission is $1.00. Sellers' tables are $6.00 in advance and $8.00 at the door, if available. Talk-in on .19/.79 and .52. For table reservations, send a check to 19-79 Repeater Association, PO Box 171, Chelsea MA 02150.

CHATTANOOGA TN
OCT 23-24

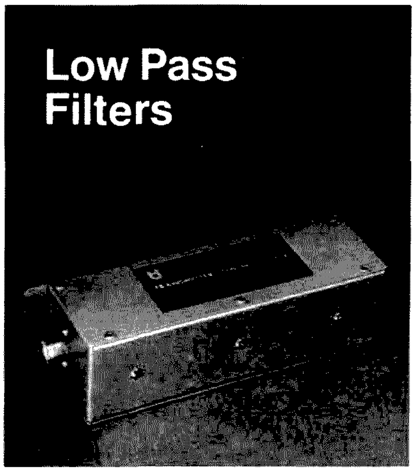
The Tennessee State ARRL Convention will feature Hamfest Chattanooga, to be held on October 23-24, 1982 at Chattanooga State Technical Community College, Amnicola Highway, Chattanooga TN. Admission is free. There will be top prizes, acres of free parking, indoor and outdoor flea markets, and a spacious dealer area inside the physical education building. Other features will include a hospitality party, a Woufl Hong ceremony, ladies' and children's activities, and a cafeteria serving breakfast and lunch. Talk-in on 146.19/.79. For further information, write Hamfest, PO Box 3377, Chattanooga TN 37404.

SAVANNAH GA
OCT 23-24

The Amateur Radio Club of Savannah will hold a hamfest on October 23-24, 1982, at the National Guard Armory, Eisenhower Drive, Savannah GA. Tickets are $2.50 in advance and $3.00 at the gate. Tables are $7.00 for the first table and $5.00 for additional tables. There will be dealers, door prizes, a flea market, and refreshments. Talk-in on .37/.97 and .28/.88. For further information, write Amateur Radio Club of Savannah Hamfest, PO Box 13342, Savannah GA 31406.

FRAMINGHAM MA
OCT 31

The Framingham Amateur Radio Association, Inc., will hold its 7th annual fall flea market on Sunday, October 31, 1982, at a new and larger location (diagonally across from the previous location) at the Framingham Civic League Building, 214 Concord Street (Route 126), downtown Framingham MA. Doors will open at 10:00 am but sellers may begin setting up at 8:30 am. Admission is $2.00; tables are $10.00 and pre-registration



Eliminates or greatly reduces interference to TV receivers by radio amateur stations when installed in antenna lines of those transmitters. Input and output impedance 50 ohms. Insertion loss .3 dB max. VSWR 1.2:1
Attentuation greater than 80 dB from 54 Mhz to 216 MHz (Typically 90-100 dB on Channel 2)
Size: 7 7/8" × 2 7/32" × 2 5/32"

Write for complete specifications.

NORTH HAVEN CT
NOV 7

The Southcentral Connecticut Amateur Radio Association's (SCARA's) third annual electronics flea market will be held on Sunday, November 7, 1982, indoors at the North Haven Recreation Center on Linsley Street in North Haven CT. Regular admission is $1.25; children under 12 with an adult will be admitted free. Sellers' spaces are $6.00. The best spaces will be assigned first. A limited number of free tables will be provided to the first reservations received. When those tables are gone, space will be available for selling from the floor or from your own table. Food will be available. Sellers may set up at 8:00 am, and walk-ins will be admitted from 9:00 until 3:00. For reservations, send check or money order payable to "SCARA" to Ed Goldberg WA1ZZO, 433 Ellsworth Avenue, New Haven CT 06511. Include an SASE for confirmation.

BANGKOK THAILAND
NOV 12-14

The Radio Amateur Society of Thailand (RAST) will hold the 12th annual South East Asia Network Convention (SEANET 82) on Friday, Saturday, and Sunday, November 12-14, 1982, at the Imperial Hotel, Bangkok, Thailand. There will be lectures, discussions, and commercial exhibits. For more details, contact RAST Secretary, PO Box 2008, Bangkok, Thailand.

NEWMARKET ONT CANADA
NOV 13

The York Region ARC will hold its annual flea market on Saturday, November 13, 1982, from 0800 to 1400 EST, at the Newmarket Community Centre, Newmarket, Ontario. Doors will open at 0630 for exhibitors. General admission is $2.00 (children will be admitted free of charge if accompanied by an adult). Refreshments will be available. Exhibitors' tables are $2.00 each. Talk-in on 142.52 (VE3YRA) and 147.225/.825 (VE3YRC).

FORT WAYNE IN
NOV 14

The Allen County Amateur Radio Technical Society, Inc. (AC-ARTS), will hold the 10th annual Fort Wayne Hamfest on November 14, 1982, at the Allen County Memorial Coliseum, Fort Wayne IN. Admission is $2.50 in advance and $3.00 at the door; children under age 11 will be admitted free. Regular tables are $6.00 and premium tables are $20.00. The Coliseum charges a $1.00 parking fee. Doors will open to the general public at 8:00 am and for vendor setups at 5:00 am. For further ticket or table information, write Becky Skinner KA9GWE, 9720 Pinto Lane, Fort Wayne IN 46804.

GREENSBORO NC
NOV 27-28

The Greensboro Amateur Radio Club will hold the second annual Greensboro Hamfest on November 27-28, 1982, at the National Guard Armory, Greensboro NC. The hours will be 9:00 am to 5:00 pm on November 27th and 9:00 am to 3:00 pm on November 28th. Pre-registration before November 12, 1982, is $3.00 and registration at the door is $4.00. There will be tables and tailgating available. Talk-in on 145.25, .19/.79, and .52. For pre-registration (please include an SASE) or more details, contact Russ Brandt KE4KL, 1301 Dayton Street, Greensboro NC 27407.

STONY BROOK LI NY
NOV 28

The Radio Central Amateur Radio Club will hold its fourth annual Ham-Central, 1982 edition, on Sunday, November 28, 1982, in the main social hall of Temple Isaiah, 1404 Stony Brook Road, Stony Brook LI NY (about 50 miles east of New York City). Doors will open at 7:30 am for sellers and dealers and at 8:30 for the general public. Admission is $2.00 and XYLs and children under 12 will be admitted free. Nine-foot tables are $5.00 each and half tables are $3.00. Features will include an updated antenna lecture by Art (W2LH) and Madeline (W2EEO) Greenberg, door prizes, and home-cooked hot food and drinks. Talk-in on 144.550/145.150 (WA2UEC) and 146.52. For additional information, maps, and advance reservations, contact Scotty Policastro KA2EQW, 80 7th Street, Bohemia NY 11716, (516)-589-2557; or Bob Yarmus K2RGZ, 3 Haven Court, Lake Grove NY 11755, (516)-981-2709.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 8

wasn't much I could tell from them. They seemed to indicate that Read, operating under the name of Global Communications (thought that was RCA!), had a contract with Chile to run propagation tests using the ham bands from San Felix. The payment: $25,000. Not bad pay for making 700 ham contacts!

The Chileans are saying that he was never there. Well, having seen people get bum raps before, I kept my mind reasonably open and asked our people to try to reach Read. No luck. The phone numbers on the Global Communications letterhead were disconnected with no forwarding numbers. The phone company had no listing for the firm. The letter was mailed from Greece, with no address or phone number.

Then came a coincidence. I really enjoy it when something happens which would be laughed at in a fiction story because it is too pat. This time I was talking with a chap who runs a ham store and we were discussing some of the times when hams had paid him off with bad checks. He told me a most interesting story about a chap who had bought a hand transceiver and paid for it with a rubber check. It looked strange to him when the chap was unable to produce a driver's license, but he had a company letterhead for Global Communications. "Hold it!" I yelled.

I had him run over the story again after telling him about Bob Read and the CE0X story.

It seems that when the check bounced back from a closed account, they had tried two Global Communications phone numbers...disconnected. Then a couple years later, one of the salesmen in the store recognized Read when he came in. The word was quietly passed. Read wanted to buy a duplexer. This had to be ordered, so they took his order and promised shipment. Global Communications again. Instead of shipping a duplexer, they made up a box the right size and put a piece of wood in the top with the duplexer knobs glued down on it so it looked as if there were a duplexer in the box on casual inspection. They weighted the box so it would feel right, mounted the old bounced check inside, shipped it to Global, and awaited results.

A few weeks went by and then one morning there was a long-distance call from Saudi Arabia and a barely audible voice yelling, "You guys are going to be sorry!"

The next day a chap came in needing a duplexer immediately. Seems his friend was in Saudi Arabia and he had promised to deliver one there; he had to ship it over by air that day. He paid cash, you may be sure.

I looked up the call KF1O in the *Callbook*, but it isn't listed. The store owner involved had the idea that the chap wasn't really a ham but was just pretending to be. That might take some checking. His letter from Greece included a QSL card with the call.

Now, it may well be that there are some explanations for all of this. If so, I'm sure many of you join me in being curious about them. Just on the surface, from what I've heard and read, it sure is curious.

Notes keep coming in about good old Mr. Read. Either he has the worst press agent since Don Miller or else he is a bunch of bad news. I wish we could locate him to clarify reports of skipping bail on bad check charges, of unpaid-for Collins rigs, unpaid-for airline tickets, unpaid-for leased Mercedes, and things like that. Does anyone know where we can reach KF1O so we can get the straight story on all these mounting charges? Read must be one hell of a smooth talker if there is any truth to all these reports.

UNTOLD WEALTH

Well, it looks as if I've struck again. The TVRO material in *73* can, if you find yourself getting interested in it, lay the groundwork for getting into what is going to be a huge industry within a few years. I'm referring to the coming direct television broadcasting from satellites.

Sometimes I get discouraged. On the one hand I get letters from readers who thank me for getting them into new businesses such as home security, computers, and so on, telling me that I provided the impetus to get them going and that they've done well. Indeed, many have become wealthy. But then I still get letters saying that some poor reader can't afford a subscription. Now, with all that money out there just waiting to be grabbed, how can anyone be short of cash?

There are so many businesses that you can start at home, on your own time, with a very small investment, that one has to be awfully lazy to miss out. I suppose it is easier to make do with very little money and enjoy watching television rather than working one's butt off to start a home business. It *is* work, have no doubt about it.

There are still almost unlimited opportunities to sell security systems and service them. The computer field is still in its early stages of growth. I know someone setting up home sales of turnkey computer systems where it's possible to make about $2,000 profit on each sale...and *any* small business in the area is a good prospect for a sale. Now we're beginning to see the proliferation of software stores, something I predicted several years ago. Two outfits are already franchising them...and there will be more.

Once we start seeing direct television broadcasts from satellites, we are going to see billions of dollars in equipment sales and in service contracts. Knowing this, I assume that many readers of *73* will yawn, pick up a beer, and turn to the cable 24-hour-a-day sports channel. Well, the gold goes to those who go get it. The articles in *73* can, if you start paying attention to them, help to give you some of the experience you will need to cope with direct broadcasting.

SOMEONE NEEDS HELP!

Almost every part of our country is covered by at least one repeater, so when you think about it, we already have the backbone for a wonderful emergency alerting system. The communications medium is there, ready for use 24 hours a day, in good propagation or bad. We're just not using it with much efficiency.

Any of you who have spent many hours monitoring a repeater channel know why most of us do not do it. Talk about boring! With all due lack of respect, a conversation about where some mobiling ham is located at the moment may be fascinating to him, but not to anyone else. Long discussions about signal strengths fall kind of flat, too, particularly when the second station in the contact is only making the repeater a tenth of the time.

Then there are those never-ending tries at autopatching from a station just a bit out of range. Well, you know why *you* don't listen to the local repeater very often.

Before you get mad at me for putting two-meter ops down, let me explain that one of the reasons I'm not heard all that often on repeaters is that I've found that I fall into the same bad habits when I call in. I drive rather vigorously and thus have to put most of my concentration on my driving. The shreds of my brain left to handle my two-meter contacts are not enough to dredge up much in the way of interesting talk. I can talk or I can drive, but I can't do both with brilliance and neither can many other people, judging from what I've heard.

Okay, if we are going to monitor a repeater all the time so that we will hear the alerting call when it comes through, we are going to have to put in some sort of automatic alarm system. And if we are going to interest many hams in participating, it is going to have to be relatively inexpensive.

First, let me say that I'm wide open for any ideas for such a system. I'd love to have someone invent it and write it up for *73*. If you do, I'll try to find a manufacturer for it...with a royalty for you. Lacking that, perhaps one of the firms in the ham field will come up with a simple alerting system, in which case I'll still be interested in publishing articles on it and helping them sell the gear.

Thinking about what kind of system might fit the bill, I note

that many of us seem to spend the few bucks extra to put a touchtone pad on our HTs. TT decoder chips are not terribly expensive, so perhaps a little IC decoder can be made which will do the job. It could even be powered by the audio output of a rig and be flipped on with a certain set of tone signals.

If I were sitting in my lab building the project, I would design it to ignore any tone signals other than the wanted ones. Let's say that we decide on using the #2 and #3 keys, the "C" and "D" keys, if you will, since CD is not difficult to remember. Our decoder would ignore any tones not starting with a #2, thus keeping down the falsing. A system which gives false alerts is not going to be of much value.

That's just one idea...with the concept of keeping the whole system as simple as possible and yet relatively false-proof. If you have what you think is a better idea, why not put a unit together, test it out, and write an article on it?

I hope there is no argument about the need for a universal alerting system. Not only is this needed for local emergencies, but for national drills. There *should* be some way of getting in touch with *every* member of a repeater group, night or day, at home or at work.

S-9 GONE, TOO

Cowan Publishing, which for years published *CQ Magazine* and *S-9*, recently turned *S-9* over to another magazine to fulfill the circulation responsibilities. That's about the end of Cowan, I think.

CQ, which was in its heyday in the late 50s, was owned by a non-ham and run as a family business. It was losing money in January, 1955, when I came on as editor. Within a few months, by changing the magazine from a column-oriented publication to an aggressive magazine for builders, I got it into the black. Indeed, by 1959 I had it going so well that it made over $100,000 in profits, which was a good deal of money for those days. Publishing *can* be very profitable.

After several battles over trying to get them to pay my authors for articles, I was finally fired in January, 1960. I had checked the books and found them to be as much as a year and a half behind on paying authors, with few paid within a year of publication. I ended up having to pay for material out of my own pocket (for which I was never reimbursed, despite promises...a loss of about $10,000 ...which also was a lot of money back then) in order to keep the magazine going.

That's when I started *73* and aimed it at doing what I had wanted to do with *CQ*...get hams interested in building. *CQ* went back to monthly columns, with little in the way of articles and circulation gradually dwindled down. Insiders told me that their circulation had dropped well below 10,000. Every now and then Cowan would write an editorial saying that he had neglected *CQ*, but that all that was changed and it would be made better. Nothing happened. Eventually he got tired of the losses and "sold" it to his editors.

S-9 went the same route, essentially. It just gradually faded away of neglect. Funny thing, for when CB was riding high, I was under a great deal of pressure from my advertising sales manager to start a CB magazine. I didn't believe that CB would continue its popularity, so I held back. Good move.

S-9 was absorbed by *CB Magazine*. Oh, it has a recent new name, but I forget what it is. It's improved of late due to the entry of Gordon West. It's now a sort of combination CB, SWL, pre-Novice magazine.

I think we learn more from the screwings we get than from our successes. I know that I sure learned how *not* to run a magazine from Cowan...and perhaps that was worth the year's pay he still owes me.

REVIEW

THE ICOM IC-730 HF TRANSCEIVER

The Icom IC-730 HF transceiver is the product of an engineering philosophy dedicated to offering as much radio in as small a package at as low a price as is feasible. Icom currently offers two HF transceivers (the other is the IC-720A), but the design concepts behind the IC-730 more closely resemble the no-longer-available IC-701 than they do the IC-720A. Because of this, we'll be comparing the IC-730 primarily to the IC-701.

Sitting flat on a table, the IC-730 measures just over 4 inches tall, 9½ inches wide, and 10¾ inches deep, making it considerably smaller than either the IC-701 or the IC-720A. In addition to its unique features, it offers the usual amenities we have come to take for granted in an HF transceiver: RIT, rf gain control, digital readout, speech processor, VOX, fast/slow agc, noise blanker (with two widths), i-f shift, and a full 100 Watts output (minimum) from the same finals that were used in the IC-701. No tune-up peaking or tweaking is necessary in either transmit or receive mode. On the bandswitch, AM is present along with SSB, CW, and a narrow CW position. The front panel is well laid out, a factor of great importance to both the dedicated DX-hound and the mobile operator.

Special Features

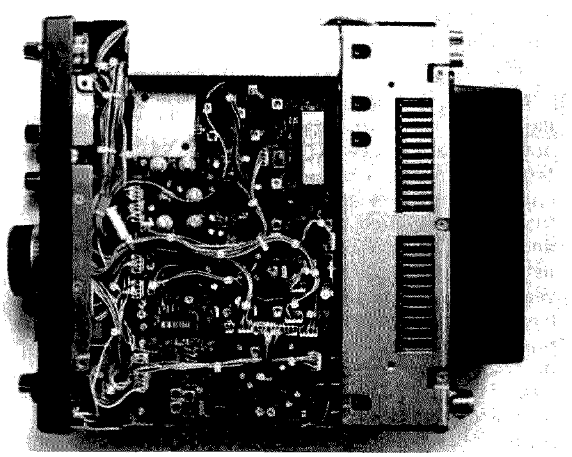
Like the IC-701, the 730 sports fully synthesized tuning. Three interlocking push-button switches to the right of the main tuning knob select the tuning rate, which can be In 1-kHz, 100-Hz, or even 10-Hz steps. While some prefer continuous tuning, we feel that the many advantages of step tuning far outweigh any of the supposed disadvantages. The 10-Hz-per-step tuning makes for a positively luxurious bandspread—one complete revolution of the tuning knob changes frequency by only 1 kHz! When speed is of the essence, selecting the 1-kHz-per-step rate will allow you to get from the low end of the CW band to the high end of phone in two seconds flat.

Just beneath the tuning rate switches is the LOCK switch which electronically locks the 730 on the displayed frequency. Engage it and the main tuning knob is disabled. If you've ever bumped the vfo knob just as a rare DX station returns your call, you'll appreciate this feature! The RIT control operates even when the LOCK is on.

Icom transceivers are famous for their dual vfo's, so there are no surprises here. The IC-730 has two vfo's controlled by a four-bit microprocessor. They can be used separately as memories, keeping track of activity on two different frequencies, or they can be used together for split RX/TX operation. When you consider how much you normally pay for an external vfo, you begin to realize how much of a bargain the IC-730 really is!

There is also a separate memory for each band which can be programmed independently of either vfo. We've used virtually every HF rig which incorporates memory functions, and the IC-730 is the first unit we've seen

Front view of the IC-730.



Top view of the IC-730. Note liberal use of wiring harnesses and plug-in connectors.

which forced us to get out the manual to help figure out memory function. Fortunately, once you read through the examples, all becomes clear. Perhaps rewording the front-panel labels would speed comprehension! If you often operate on specific frequencies, you'll appreciate the memory backup feature. As long as there is 12 V at the memory backup connection, the memories are not lost when power is shut off.

As is becoming common these days, metering is sparse. The IC-701 allowed you to view S-units, ALC, compression, collector current, voltage, and rf output. With the IC-730, you'll have to make do with ALC and rf output.

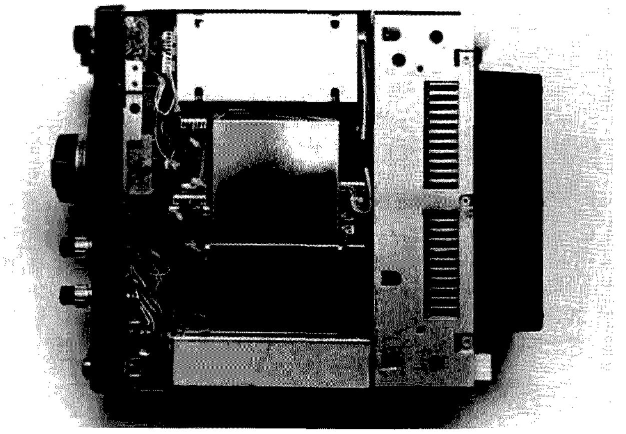
An extremely welcome innovation is the built-in preamp. While this may appear to be a gimmick, anyone who has used a good preamp can attest to its usefulness. The preamp is located between the low-pass filters and bandpass filters, and, when switched in, exhibits about 12 dB of gain.

The IC-730 covers all ham bands between 80 and 10 meters, with generous amounts of coverage above and below each band. Our sample tuned everything between 3.4 and 4.01 MHz, 6.9 and 7.6 MHz, 9.9 and 10.6 MHz, 13.9 and 14.6 MHz, 17.9 and 18.6 MHz, 20.9 and 21.6 MHz, 24.4 and 25.1 MHz, and 27.9 and 30.1 MHz. The 10-meter band has four separate sections on the bandswitch.

The microphone connector is an eight-pin affair with pins to allow up and down scanning with a push-button microphone. Much to our surprise, the wiring diagram in the manual includes only the pinouts for PTT and audio. Icom apparently feels that hams cannot be trusted to wire their own scanning microphones! The scanning capabilities are convenient for hams who wish to remote-control the rig for some reason, and it's a shame that Icom didn't come right out and tell us which pin does what. If you intend to use these pins, make sure you know exactly what's what. Short the wrong pins and you'll watch blue smoke curling into the air!

Several controls are hidden away beneath a small port on top of the rig. Theoretically, these are controls which seldom need adjustment. There are pots for sidetone audio level, anti-VOX, VOX gain, VOX delay, frequency calibration, and swr set. There are miniature slide switches for noise blanker wide/narrow, speech processor on/off, and swr forward/reflected. Icom's judgment was sound on all but the speech processor. We'd really prefer to have that switch located on the front panel, particularly since the access port will be completely inaccessible in most mobile installations. On the bright side, Icom's speech processor is exceptionally clean and distortion-free. If properly adjusted, there is no reason why it can't be left on all the time.

On the left side of the rear panel are the power socket, *ground connection, and* antenna connector. The middle area is occupied by the heat sink and fan for the final amplifier. On the right side is a jack that can be wired for either memory backup or amplifier relay switching. There are also jacks for ALC input, speaker output, CW key, and a multi-pin accessory socket with all the necessary signals available for transverters, phone patches, and bandswitching for the IC-2KL linear amplifier. There is no direct access to the microprocessor as there was with the IC-701.



Bottom view of the IC-730. Note the extensive internal shielding.

Inside the IC-730

The layout inside is light-years ahead of its predecessor. There is liberal use of small boards interconnected with plugs and jacks, making servicing easier on everybody. A great deal of internal shielding is employed, which probably accounts in part for its immunity to RFI from microcomputers.

The instruction manual is reasonably good, although it is obviously targetted at the appliance operator. Some Japanese manufacturers (like Yaesu) are including more and better service information with each new rig they introduce. Icom seems to have taken a step backward, for the manual supplied with the IC-730 is not as complete as the one we received with our IC-701! The IC-701 was supplied with charts of voltage readings at critical locations and more or less complete sections on theory of operation and alignment. No alignment instructions are furnished with the IC-730, and the circuit description is not particularly informative since no mention is made of specific components. Fortunately, there is a large fold-out schematic, and an even larger board layout diagram. Emergency repairs could probably be made from this information, but hams planning to take on their own maintenance and repairs by choice or necessity would do well to pester Icom America for more complete service data.

The Power Supply

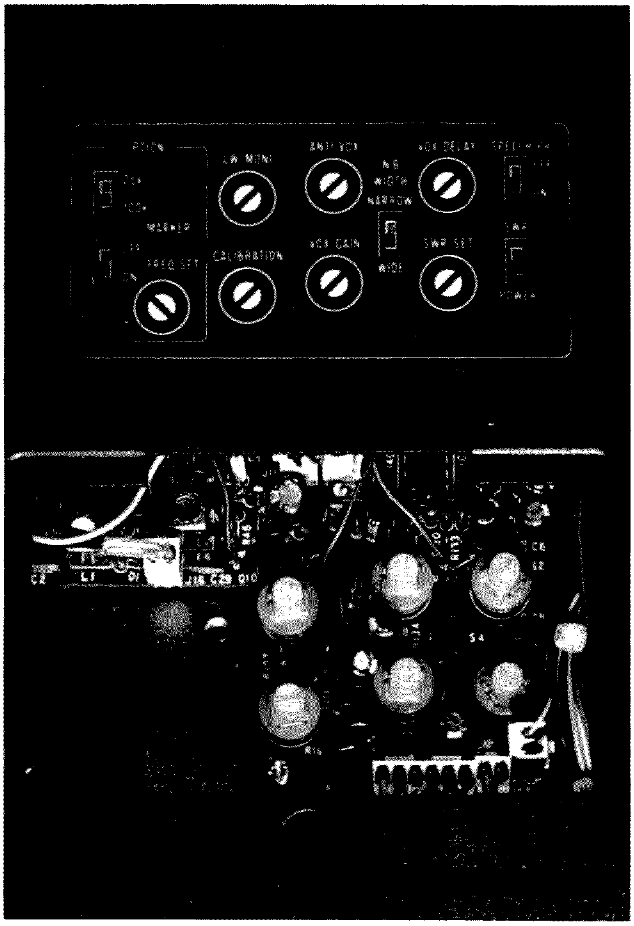
Our review sample was supplied with the IC-PS15 power supply, rated at 12 V dc and 20 A, with a 10-minutes-on, 10-minutes-off 50% duty cycle. It is well regulated and probably adequate for casual operators, but contesters and serious CW operators might do well to look into a heftier supply. As is the case with many 12-volt power supplies from transceiver manufacturers, the PS15 is designed to work only with the rig it matches, so it can't be used with other station equipment. Moreover, it only superficially matches the rig in appearance and lacks the traditional front-firing speaker. Considering the price tag, a hefty well-regulated 20- or 30-Amp supply from a reputable power supply manufacturer might be a better choice.

Accessories

The IC-730 is supplied with a preamplified hand microphone, a bag of plugs, and a hefty dc power-supply cable. Accessories available at extra cost are a marker unit with output every 25 or 100 kHz, a 500-Hz CW filter, a CW audio filter, full passband tuning, base station microphone, scanning hand-held microphone, mobile mounting bracket, external speaker, phone patch, and power supply.

On the Air

From the moment you turn it on, it's obvious that the IC-730 is a top-notch rig. We were a little



Access port on top of unit. Blank space in bottom left corner is for optional marker unit.

concerned about the quad-conversion design and birdies, but the 730 uses up-conversion with i-f's at 39.7315 MHz, 9.0115 MHz, and 455 kHz, reducing these problems to a minimum. Careful listening without an antenna turned up a couple of weak birdies inside the ham bands, but they didn't even move the S-meter. Outside the ham bands, we found only a few louder signals, ranging from S-3 to S-5. Not bad!

RTTY operators should note that the IC-730 is very well protected against RFI from microcomputers. With an antenna located some distance away, we placed the 730 three inches away from a disk-equipped TRS-80 Model III and heard no RFI at all. Most other rigs we've tested suffer varying levels of interference under these conditions.

Received audio quality is excellent, and there's lots of it. We used the IC-730 in a noisy car for several weeks without any external speaker, and it was fine. There seems to be more high-frequency audio available than there was in the IC-701, which makes speech easier to understand. As with every other rig we've tested, lots of internally-generated hiss and noise can be heard, even when no antenna is connected. Transmit audio was excellent, with most other hams reporting that audio quality was best with the speech processor in the "on" position. On the negative side of the ledger, the cooling fan runs continuously in the transmit mode, and also in the receive mode if the rig is overheated. We found noise from the fan slightly annoying in a quiet room, although it is much quieter than the fans in high-power amplifiers.

As for general receiver performance, the IC-730 seems to be more sensitive than the IC-701, and audio quality is substantially improved. Dynamic range was quite good, too. Serious CW operators will probably not be happy until they install a CW filter, however.

We really don't enjoy torturing equipment, but we felt obligated to run a few tests in the interest of science. With the rig in the transmit mode at full output, we flicked off the power switch and turned it back on again a few seconds later. Another solid-state transceiver we were considering for review blew an internal soldered-in fuse when subjected to this treatment. It took an hour to find and replace! The IC-730 (and the PS15) showed better manners and never missed a beat. While some might consider this test unreasonable, it is vital that a rig be able to pass it if it is expected to operate under emergency conditions.

To test the swr protection circuitry, we transmitted into a variety of less-than-perfect loads. We also tried a couple minutes of transmission with no load at all. No problems developed. We performed similar tests on our IC-701 when we first received it, and after three years of hard use, often under less than optimal conditions, the original finals are just fine, thank you! While there is undoubtedly a particular combination of load, rig, and idiot that will blow the finals, all indications are that the IC-730's final amplifier will be highly reliable.

Hams who find an attenuator indispensable should be aware that there is none on the IC-730. In all fairness, we must say that while we have encountered many operators who have professed great regard for these devices, we have never seen them actually use one on a modern rig!

Conclusions

Several months of use have left us with nothing but respect for Icom's compact HF transceiver. Indeed, returning it leaves us with a feeling of great loss! The only thing we'd like to see added is a good notch filter and perhaps a RTTY input for direct FSK. Practically speaking, though, neither of these are available on other compact transceivers.

For our style of operation, the IC-730 is one of the best transceivers we have yet encountered, regardless of size or price. Most intriguing of all, it appears as though the little IC-730 might stand up well to the rigors of DXpeditioning. If you are looking for a small transceiver but are unwilling to compromise on performance or give up features, the IC-730 deserves serious consideration. LICENSE PLATE HOLDER

If you happen to live in one of those states where only a single license plate is required and you're a radio amateur to boot, Vani-Plate has something that you'll be interested in: a vanity plate holder *and* the plate to go with it!

You can dress up that bare front bumper with a personalized vanity plate showing your raised callsign in white or black on a variety of colored backgrounds, framed in a chrome bracket which sets it off attractively on your vehicle.

The mounting plate is made of Plexiglas® and is available in background colors of blue, white, black, red, or brown. Alternatively, you may choose the "fleck" background with a

The Vani-Plate.

Spider antenna from Multiband.

"pearl" appearance in red, green, gold, blue, or silver.

The standard plate costs $9.95; the fleck background is an additional $3.00. A heavy chrome frame is $2.99, while a deluxe chrome frame is $7.99. UPS charge is $1.95.

For additional information (catalog: 25¢), contact *Vani-Plate Company, PO Box 136, West Yarmouth MA 02673.* Reader Service number 481.

MULTIBAND ANTENNAS

The first time I saw the Spider antenna, I was intrigued with the unusual design and wondered why anyone would put something like that on a car. The location was San Diego, and the event was the ARRL Southwestern Division Convention and "Hamputer" fest.

Fred Schmitka of Multiband Antennas had a booth there, and he had several of these mobile antennas conveniently mounted at the booth which caused a lot of gawking and a lot of stopping to question Fred all about the whys and wherefores. I was one of the stoppers and gawkers, too, and learned that Fred and his brother Len have spent several years perfecting—and patenting—the Spider.

Basically, the Spider is a mobile antenna that permits operation on 10, 15, 20, and 40 meters from your car. The antenna consists of an aluminum (or stainless steel, if you prefer) mast section about four feet high, with four "fingers" protruding from the top at various angles. The 40-meter finger sticks straight up, more or less as a continuation of the mast, while the 10-, 15-, and 20-meter fingers are arranged radially around the mast at about 120-degree spacing, like the spokes of a wheel. Each finger also tilts about 45 degrees from the vertical. These fingers are the resonating elements for the four bands and consist of fiberglass rods or tubes helically wound with wire and covered with a tough, transparent plastic. An index scale is molded into each element so that adjustment to exact frequency can be made. This adjustment is provided by sliding a short tubular section along the resonator element until minimum reflected power is measured at the feedpoint of the antenna.

The big advantage of the four separate resonating elements is the fact that the antenna is fully and automatically bandswitchable without the driver ever leaving his seat. You merely pre-adjust each resonator to your favorite frequency within the band, and that's it. . . or so Fred assured me. He also suggested that the mobileer not use a base spring to mount the antenna on the car, but instead use a solid mount to keep the antenna vertical, even at highway speeds.

Well, I was fascinated by the idea, and Fred kept assuring me that the antenna worked as billed and that the helical resonating elements placed at the top of the antenna provided the highest possible position for maximum current (i.e., top loading, exactly where you want the current maximum in a mobile installation). To make a long story short, I had one shipped to *73* HQ for a test. I also asked Fred to include a bumper mount for my 1980 Olds Omega and a quick-disconnect fitting to prevent unwanted and undesirable removal by my garage door or other low overheads. Of course, Fred didn't have anything that would remind me to remove the antenna before driving in, so that part is up to me. At least I'd be all set to quickly remove the Spider should I remember in time.

The afternoon of the Fourth of July was spent installing the antenna on the car. I made a secure bumper mount, assembled the antenna according to the instructions, and with great trepidation fired up the rig. What's this? Signals coming in at S-9 on 40 meters in mid-afternoon? Hmmm. . . let's try 20. Yep, signals there, too; and on 15, and 10, too.

I connected my swr bridge into the line at the base of the antenna and put a very small amount of rf into the antenna starting with the 20-meter band and my favorite frequency there. A couple of slides of the slider tube and the meter showed zero reflected power. Wondering about possible interaction, I tuned up to 40 in the same way, and then 15, and then finally 10. Fully expecting to have to go back and readjust each one because of interaction, I was amazed to find that the original settings still held and that no retuning was needed.

Now for the proof test. . . the so-called moment of truth. I heard W2JAU in New York calling CQ on 40, so I gave him a quick reply. He came back and said that I was 5-8 in Brooklyn! "Pretty good signal for a mobile," Ben said. "What are you using?" Well, have you ever tried to describe something like a Spider over the air? No? Well, you've got a treat coming. After a nice long, solid QSO with Ben, I decided to try 15. I answered EC4AQS in Spain and OE8LKK in Austria. The Spanish station was very QSB, but we did have a good QSO. The Austrian station was loud, and that QSO was much better. . . but still the band was not in very good shape. Nevertheless, we managed to work out quite well, considering that my driveway is not the best DX QTH in the world. Back to 40 meters, I contacted Bill VE3BDO in Ottawa who was using his recently acquired GFT-ONE. We gave each other 5-8 to 5-9 reports and talked a bit about our new toys.

The rig I used was a venerable TS-520S which didn't even know it was in the car. . . since it loaded just as well as it ever does on the fixed-station antennas. Now to try the bandwidth and how far I could go without exceeding a 2:1 swr.

On 40, I could move close to 50 kHz without exceeding 2:1 vswr. On 15, it was better than 100 kHz, as it was on 10. What about 20, you ask? Well, to be honest, I hadn't tried 20 by the end of the first afternoon; that had to wait for July 5th—another holiday—and results were equivalent to those on the other bands. My first answer brought W8TA in Detroit (short skip QSO) and a 5-7 report. Bill's signal was also about 5-7 to 5-8, and we had a good chat. Bandwidth without retuning the resonators was about 75 kHz. Here it should be mentioned that each resonator is wound long purposely so that resonance can be obtained below the bottom band edge. (This is a feature which appeals to MARS operators. If it is desired to achieve resonance at the top edge of the band, it may

be necessary to remove some turns of the coil.[1])

I should mention that I also chatted with Chuck W2WGL in Utica, New York, on SSB. He gave me a good 5-7 report on 40-meter phone and remarked at the steady signal. Well, it ought to have been... I was parked!

Unfortunately, 10 was not open, so I haven't been able to make any QSOs... but I'll keep trying! With a good band opening, there ought to be plenty of stations willing and able to work W1XU mobile.

One more thing I ought to mention about the Spider antennas... or maybe a couple more things: First, the fact that if you already have a base rod from a Hustler, for example, you can get an adapter from Fred to adapt your base rod to his Spider. It's the economical thing to do and works just great. You can use either antenna whenever you wish... just by changing from one top, or resonating, section to the other. The second thing I want to mention is that the Spider antennas might very well be excellent for use in mobile homes, RVs, apartments, or what have you, where a limited-space antenna is mandatory. One precaution, though: Be sure to use an adequate ground plane... like the chassis of your car. When you don't have such a ground plane, use radials, a railing, a counterpoise, or whatever you can find that will serve the same purpose. One trick passed on to me long ago by a ham whose name I've long since forgotten is to use a piece of four-conductor rotor cable as your ground plane or counterpoise. Just cut each of the conductors, one per band, to the quarter-wavelength-plus-2½% formula. They really work and provide the much-needed "phantom" antenna. This can be a big help in apartments and condos.

Maybe if the super asks what that funny thing is that is attached to your balcony railing, you can say that it is a clothes-tree. Most of us, however, will find the Spider in use on our vehicles, whatever they may be. Travel trailers are excellent for the Spider, too.

Perhaps the best thing about the antenna is that it can be tuned to your favorite part of the band and forgotten unless you want to really change to another part of the band entirely, in which case you merely adjust the slider. An afternoon of doing a frequency plot vs. index markings on the resonators will arm you with the data you need for almost instant band changing. The reason that Fred and Len don't provide frequency vs. index marking information is because each installation will be different, and what's sauce for the goose ain't necessarily so for the gander. Thus, you'll have to go through the tuning and pruning operation once when you first install the antenna. After that, it's all downhill. Besides, you want to do *something*, don't you?

Finally, I have to say that the workmanship is solid, functional, and efficient. As for beautiful, all I can say is what my grandmother used to say: "Pretty is as pretty does." The Spider is therefore beautiful by definition, because it does pretty well indeed. Don't take my word for it, try one yourself... you'll be glad you did.

For more information, contact *Multiband Antennas, 7131 Owensmouth Ave., Canoga Park CA 91303*. Reader Service number 476.

Jim Gray W1XU
***73 Magazine* Staff**

[1] In my tests I noticed that on 40 meters with the tuning ring slipped all the way to the bottom of the resonator, I could just achieve unity swr at about 7150 kHz. Yet, with the ring only halfway up the resonator, I was able to achieve unity swr at 7.005 kHz. This means to me that there is a lot of room for pruning the resonators so that adjustment of the sliding ring will achieve unity swr at both band edges. To prune, just slip off the plastic cap and carefully peel turns loose. After removing turns, carefully cut the wire and throw the excess away. Tuck the remaining end back into the resonator and recap it.

CUSHCRAFT R-3 HALF-WAVE VERTICAL

We all remember the old cliches about vertical antennas, but the problem is that most of them weren't true. I've used vertical antennas with good success over the years and have owned most of the brands on the market at one time or another.

Oh sure, if you insisted on ground mounting your vertical, refused to place it in the clear, and just drove any old kind of ground rod into the soil instead of furnishing decent radials, you were disappointed... and have only yourself to blame. On the other hand, if you placed that vertical at a decent height, provided a set of radials at the base, and took pains to tune and prune it properly, you had a fine antenna that worked its share of DX.

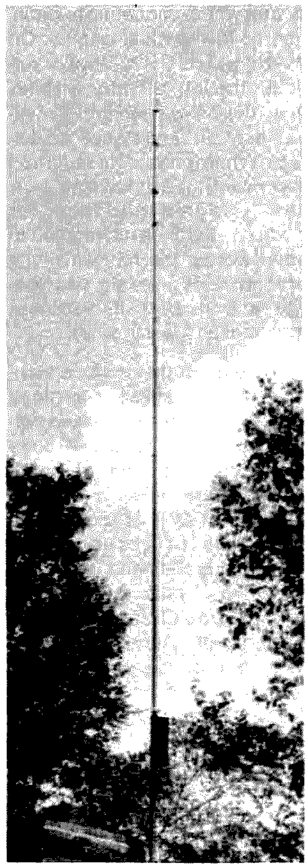
Cushcraft has long been known for its fine line of HF and VHF beam antennas, and there are few of us, indeed, who have not seen or heard them play on the various ham bands. Perhaps fewer of us have seen or used their multiband trapped quarter-wave vertical antennas, and I'm sure that fewer still have really paid sufficient attention to what Cushcraft has accomplished with their new R-3. Believe me, it's a breakthrough!

Let's go back for a minute or two and review what we know about vertical antenna patterns... particularly the best-known and most popular vertical, the quarter-wave ground-plane vertical... to establish a basis for discussion of the R-3.

Most hams turn to verticals as space-saving antennas when they don't have room to erect larger arrays such as horizontal dipoles, beams, extended wire antennas of all kinds, and others that require reasonable (sometimes unreasonable) amounts of real estate to own and operate.

Those who have used verticals with success, including those forced to use them because of space limitations, have discovered that quarter-wave verticals seem to work very well at close distances and very well at long distances. However, at mid-range distances, verticals often don't seem to work as well as conventional horizontal antennas. The reason for this seeming anomaly is the angle of radiation, specifically the vertical angle of radiation.

In order for the normal dipoles and other horizontal antennas to exhibit their best vertical radiation angles, they must be placed at least one half wavelength above the ground surface. The vertical antenna, in contrast, exhibits a very low vertical radiation angle even though its bottom end is resting on the ground. Each amateur band has a different optimum vertical angle of radiation for maximum distance transmission. For example, an optimum vertical angle of radiation for a horizontal antenna on the 20-meter band would be about 10-15 degrees for the best DX. By the time the vertical angle of radiation is as high as 20 or 30



The R-3 half-wave vertical from Cushcraft.

degrees above the horizontal, it has become a mid-range antenna and rather poor for DX. As the frequency becomes higher, the required vertical angle of radiation for best DX performance becomes lower, while the converse is also true.

Thus, for best performance as a DX antenna, a horizontal antenna must not only be physically large and take up considerable space, it must also be high... as most DXers know, the higher the better. On the other hand, vertical antennas with their naturally lower vertical angles of radiation tend to be natural DX antennas. (Be patient, readers, we're almost there.)

VHF mobile operators have found that quarter-wave ground-plane verticals, while adequate for working close-in stations on VHF, suffer when trying to really reach out, because a large portion of the radiated rf is still radiated at angles too high for line-of-sight work. The solution to this problem is the use of gain antennas, antennas which are longer than a quarter wavelength at the operating frequen-

cy and which concentrate radiation at low vertical angles. On the HF bands the half-wave vertical, though slightly shorter than the 5/8-wavelength antenna, has an additional advantage: While most of its radiation is concentrated at low angles, it has a high-angle lobe for medium distance coverage. In other words, the half-wave vertical provides good signal coverage at virtually all distances from close in to far away.

There is another major advantage of the half-wave vertical. Unlike its relatives, the quarter- and 5/8-wave verticals, it does not need a ground plane or ground-plane radials to function at its best! One of the biggest bugaboos of ground-plane antennas is the need to provide a system of radials or a nearly perfect ground for the return current path. Although the vertical part of the quarter-wave antenna is, in fact, a space saver, the radials required tend to offset much of this advantage. Those of you who have wives, mothers, or neighbors who take pride in their homes and in the appearance of the property (as do most hams, of course...ahem) know that radials in the form of wires strung around to the roof edges, adjacent trees, stakes in the ground, etc., are unsightly and inclined to arouse the worst in human nature.

Enter the R-3. Here is a vertical antenna *without radials of any kind* that covers the three most-used DX bands: 10, 15, and 20 meters. The R-3 is a true electrical half-wave vertical radiator on each of these bands. It has two traps which effectively shorten the antenna physically yet permit resonance on each of the bands. Best of all, the R-3 can be tuned to exact resonance at your desired frequency within each of the bands... remotely, right from the shack!

Inasmuch as Peterborough is only a forty-five-minute drive from Manchester, site of the ultra modern Cushcraft manufacturing facility, Bob Cushman and Glenn Whitehouse graciously invited me to pick up the R-3 myself and take a plant tour. After a pleasant and very informative walk around the plant, which included a peek at the antenna test range, the laboratory, and the production lines, I picked up the packaged R-3 in its box, tucked it into my car, and took it home.

Several major groups of components make up the R-3, each in its own container, well protected from damage and almost immune to everything but an intentional effort to destroy. You will find the CTA capacitor/motor unit in its own box, the indicator/control unit in another box, the traps and aluminum parts in the main box, and all of the hardware in a plastic bag... and I mean *tough* plastic. A complete set of illustrated instructions, with exploded assembly views and parts list with picture identifiers, completes the package.

All you need to assemble the antenna is a screwdriver, a small adjustable wrench and/or a pair of pliers, and a tape measure. The base section is assembled first by making up the matching and feed ring and attaching it to the base. Next comes the capacitor box with its internal motor, and finally the traps and aluminum tubing which, when assembled properly, becomes the R-3... all 22 feet of it. I was impressed with the quality of the aluminum, the stainless-steel hardware, the *correct* number and sizes of nuts, bolts, and washers, and the general attention to detail that characterizes this antenna. The instructions are clear and straightforward.

Having learned my lesson long ago to read the intructions first, I spent some time looking at the drawings, reading the assembly steps, and comparing hardware to the lists of same.

Wherever a dimension was given, I followed it meticulously, measuring everything carefully to see that it was correct. With the assembly drawings and exploded views, I am convinced that anyone could assemble the R-3. The entire process of making up the antenna took me exactly one hour and thirty minutes... ready for installation.

I had a chimney mount that used to support my small beam, so I decided to use that... together with a five-foot piece of TV mast tubing to which the R-3 base is bolted. If you prefer to mount your R-3 on some other kind of support, it will fit over any kind of pipe or mast up to a 2-inch diameter. I also had a suitable length of four-conductor rotor control cable salvaged from the former beam installation, so I decided to use that for the control box and remote motor hookup. Please note that when you buy your R-3 antenna at your dealer or when you order it by mail, also be sure to order enough four-conductor cable to reach from the point of installation to your operating desk where the control box is likely to be located.

At this point, I was ready to attach the coax to the antenna, so I chose the right length of RG-58/U (since I run only 200 Watts and don't anticipate using an amplifier) with a PL-259 connector on the end. Cushcraft provides a neat little neoprene sleeve that fits over the coax fitting and also gives you a tube of silicone grease to waterproof the coax connection at the CTA box. I would also recommend that you tape and waterproof the control cable connection at the connector block... just to be safe.

A quick once-over and I was ready to apply power. The control box did move the indicator needle back and forth across the dial... from below the 20-meter band markings to above the 10-meter band markings, so apparently the capacitor was moving correctly in its box. I returned it to the 20-meter position and decided to try that band first.

My swr meter was connected in the circuit, so I applied rf power to the antenna at the low end of 20 meters while I moved the switch to resonate the antenna, i.e., tune it to frequency. Suddenly, the swr began dropping, and dropping... and dropping. It fell *below* 1.1:1! Then, just as quickly, it began rising again, so I knew that I had passed the point of resonance. Unable to resist temptation, I switched back to the point of lowest reflected power, made a quick call, and raised K4OAH. "Five, nine, nine here in Atlanta, OM," came the report. After a brief chat, I moved on, working several US and foreign stations in quick succession, receiving *very* gratifying reports.

The 15-meter band didn't seem to be so hot, but I tried anyway, figuring that even if I didn't raise anyone, I could at least check out the tuning range of my R-3. Again, with actuation of the switch on the control box, I watched the swr drop further and further... and, again, it stopped below 1.1:1! What the hay, as long as I was tuned up on 15, why not call into a dead band? It couldn't hurt. Believe It or not, K4CG answered me and gave a 589 report in Alexandria, Virginia.

The R-3 was beginning to make a believer out of me.

On 10 meters, which *was* closed, I did manage to tune up as before, with the same results... and an swr below 1.5:1 at resonance. You ought to know that the instructions are very explicit about tuning, and they mention that if the antenna can't be resonated to less than 1.5:1 at the upper and lower ends of each band by merely tuning the capacitor through the control box, then you will have to change the length of the antenna slightly... all of which is carefully explained.

I figure that mine worked at the specified dimensions with no changes from the nominal ones given in the instructions because it was mounted high and in the clear, without the length-changing influences of nearby trees, wires, and ground.

To date, I have had an opportunity to use the R-3 antenna on both phone and CW in various parts of the bands and have found it unquestionably superior to my regular quarter-wave trapped vertical in terms of the signal reports that it delivers and especially in hearing signals. Being tunable to exact resonance, it tends to filter out unwanted portions of the band by exhibiting a high Q factor. I have particularly noticed its ability to hear mid-distance stations as well as DX at the same time and to work equally well on short skip and long-haul communication.

Not having a beam, but having various horizontal and vertical antennas for comparison, I can truthfully say that my R-3 outperforms them all in both received and sent signal reports. As the old saw goes, "You can't work 'em if you can't hear 'em," so the rest is up to me. No more excuses for not getting the rare ones. By the way, that brings up an interesting point: I worked VE1SPI on St. Paul with the R-3 antenna, on 15 and 20. Better still, I got them on the *first* call... in itself a relatively rare experience for me.

Is there anything that I didn't like? To be honest, no, there is not. You have to be careful in hooking up the remote control

cable, and be sure you correctly identify which pin Is which, because it will not work if you don't. Also, you have to be careful in putting up an all-metal antenna of *any* kind to prevent contact with power lines and the like. I would also highly recommend that you connect a surge protector in your coax line to bleed off accumulated static charge and minimize the possibility of a lightning strike.

To sum it up, then, I have to say that the Cushcraft R-3 packs a powerful punch in its slim and trim length, and I recommend it highly to anyone who needs a good antenna that can be erected almost anywhere *without* radials and turn in unsurpassed performance for a vertical.

For more information, contact *Cushcraft Corporation, 48 Perimeter Road, Manchester NH 03108.* Reader Service number 480.

KTI-20 POWER SUPPLY

A power supply isn't a glamor item. If it does what it should do, supply a regulated voltage at its rated current, you should be able to ignore it and concentrate on the device that is being powered. The Kem-Tron Industries KTI-20 power supply isn't glamorous and it can be ignored once safely installed in the shack.

The KTI-20 is a 13.8-volt, 20-Amp regulated supply. Its 20-Amp rating means that it isn't quite big enough to power a 200-Watt solid-state HF rig, but it will do very nicely as a supply for just about any less-current-hungry rig in your shack. The supply uses an LM723 regulator driving four pass transistors and contains a crowbar protection circuit that will shut down the supply if a regulator failure should cause the output voltage to rise above a safe level. The output voltage is variable plus or minus about ten percent around the nominal 13.8 volts.

I've used the KTI-20 in my shack for some time to power my 2m rig and, occasionally, a 160-Watt 2m amplifier. It has been left running continuously for days on end with no ill effects.The KTI-20 will drive my Mirage B3016 amplifier, but won't drive both the amp and exciter at once. That's not the supply's fault, since the two together draw almost 27 Amps.

It's a shame that this supply wasn't designed 5 or 10 Amps heavier. The 20-Amp rating is too large and too expensive to drive a low-power 2m rig and too small to drive a solid-state HF rig. But if your total power requirements at 13.8 volts can be met by a 20-Amp supply, the KTI-20 is a good choice at a price that's also a compromise between large and small supplies—$129.99.

CR2A ANTENNA FROM COM-RAD INDUSTRIES

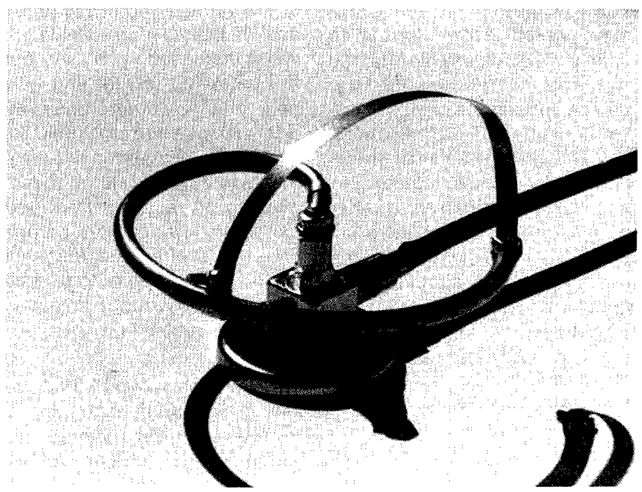
Your first impression will be "What is it?" The second may be "How does it work?" or "Hey, that's sure different—I wonder what it's for?" My neighbors thought I had left a fancy dish on the top of the car, and my wife remarked that it looked like a flying saucer (whatever *they* look like).

To me, it looks like a directional discontinuity ring radiator, or DDRR... which is exactly what it is. Okay, I guess I do owe you an explanation about the mystery, so let's take first things first.

A few months ago Jim Waldron of Com-Rad Industries (which means Compact Radiating) called me on the telephone and asked me a few questions about advertising. It seems that Jim has been playing around with antennas for years and has been particularly interested in space-saving antennas, aerials that will permit hams to operate from apartments, condominiums, mobile homes, offices, and the like.

This is all well and good when we are talking two meters and higher frequencies, but what about the HF bands? Aye, that's the rub... what *about* them? How can you operate from an apartment or condo when the landlord or the management (or your neighbors for that matter) objects to any outside antennas. What do you do if you're a DXer and an avid rag-chewer, let's say on 20 and 80 meters, respectively.

Well, Jim had thought a lot about these problems and, being a man who has done extensive travelling and his share of operating from the car, from motel rooms, and from other sites, knew about the problems. The one thing he didn't do was give up; he researched various shapes and arrangements of radiators in a variety of combinations and finally developed a combination of radiator, inductor, and capacitance that would allow him to operate on any band from ten through 80 meters with good results. Checking into the several nets he uses, he asked for reports on his signal. He asked DX stations how they copied him, and he rag-chewed with many hams all over the country... all on the space-saving designs he developed. They were successful, and he knew that others would like them or more likely *need* them.



Com-Rad's DDRR antenna.

The question he asked me was "How do I get the message across?" and my answer was advertise first in a New Products release, and second in a display ad. So we introduced the first and smallest of the Com-Rad antennas in our May, 1982, New Products section... the DDRR model CR2A.

In his travels, Jim had discovered that two meters is almost indispensable for mobile communications. However, there are problems associated with whip antennas in general, and we have all faced these from time to time in varying degrees of severity. Example: I nearly had the entire whip, mount, and coax removed from my car when I drove into the parking garage at Logan International Airport in Boston... a high-profile antenna in a low-profile environment. Another case: Using a 5/8-wave mag-mount antenna for two-meter FM, I lost the whole shebang when it blew off the car at speed (yes, it *was* a bit over 55). Once again, I had become used to the flutter, the QSB, the pruning to length, the removal of the whip before driving into my own garage... all nuisances for those of us who operate mobile.

The answer to all this came to Jim in a flash—use a rugged, low-profile antenna of solid construction. Enter the DDRR.

The CR2A antenna has a considerable height reduction over that of full-sized verticals. This lowers wind resistance and completely eliminates mobile flutter (picket fencing). The extremely low angle of radiation enables the directional discontinuity ring radiator to compare, most favorably, with most full-size units. The feed system connects the antenna directly to ground, which provides an automatic static drain from charges induced by fog, dust, and precipitation, affording an improved signal-to-noise ratio.

The DDRR has been around a long time. It was developed for use in hostile environments and in instances where lots of abuse could be expected but had to be withstood. One of the first articles about the DDRR, or "Hula Hoop" antenna as it has been called, was by J. M. Boyer in *Electronics*, January 11, 1963. He suggested that an antenna only two feet high could perform nearly as well as a 60-foot-high vertical antenna.

The problem had always been that when the vertical antenna height is reduced physically and resonance is achieved by loading with lumped reactance elements, efficiency drops drasti-

cally. In the new system, however, which Boyer termed a "leaky waveguide radiator," the circumferential aperture replaces the vertical height. The small height (only 2.5 electrical degrees) and the small diameter (about 28 electrical degrees; i.e., slightly more than a quarter wavelength) together with its ability to be tuned over a frequency range of about 2:1 and matched to transmission lines of between 36 and 500 Ohms make the DDRR an ideal antenna. Its only drawback is the need for it to be placed over the best possible continuous ground plane with very low losses. At two meters, of course, the steel automobile body serves admirably, but copper or aluminum would be even better.

Early models of the DDRR performed within a few dB of their full-size quarter-wave vertical counterparts at frequencies of between 2 and 4 MHz. However, as the frequency increased, so did the apparent efficiency (possibly because of the increased conductor diameter as a ratio to wavelength), and at 30 MHz, the DDRR was shown to be *superior* to a quarter-wave vertical antenna mounted to the same *ground plane!*

Two hams who have done extensive work with these antennas are W4MIP and W6UYH... and now Jim Waldron W1HGZ.

The Com-Rad antenna is formed of 3/8″-diameter stainless-steel tubing and is bolted to a chrome-plated roof-top magnetic mount. Stainless-steel hardware connects the single insulated wire from the mount to the ring, and a wide copper strap (actually phosphor-bronze strap about 3/8″ wide and .010″ thick) is connected between one end of the ring and a point on the circumference. The wire and the strap are adjusted to provide the lowest possible reflected power. A coaxial UHF-type chassis connector on the chromed magnetic mount is used to attach your 50-Ohm coax to the antenna, permitting it to lie flat against the car roof.

The tuning ring enables the band-center to be placed anywhere within the two-meter band and beyond, making the device useful outside of the amateur band. The tuning ring replaces the variable capacitor used with conventional DDRR designs and broadbands the system by making a large loop at the voltage end of the antenna. The high-Q of the device provides increased selectivity during reception, minimizing adjacent channel interference, image response and crosstalk. The low profile eliminates entanglements with trees, and it doesn't need to be removed from your car when you park in a garage. The low profile and magnetic mount make it easy to operate the antenna virtually anywhere a square foot of ground plane exists.

How does it work? Well, let me give you an example. As soon as I received the antenna, I mounted it on the car roof and connected it to my NDIHC-1400 two-meter synthesized transceiver by means of a piece of RG-8/U. First, I should explain that the terrain here in New Hampshire is extremely hilly. Repeaters are on hilltops here, as everywhere, but there is an awful lot of rugged terrain in between, and many shadow areas. Consequently, many of us use beams to hit the repeaters from our homes, and (at the very least) 5/8-wave whips on our cars. With a good 5/8-wave whip, and the car parked in the driveway, I can usually bring up about four or five New England repeaters, including the Derry machine, the Mt. Greylock machine, and several others. With my quarter-wave whip, things are a bit tougher. I usually have to go to the top of the mountain to bring up the machines...all except for our local repeater in town.

Thus it was with considerable interest that I put the silly-looking (but tough and rugged and low-profile) Com-Rad DDRR on the car. What the heck, I couldn't do *worse* than the whip...or *could* I? So, I scanned the band...and wait a minute! I'm hearing many repeaters. One after another, I listened, called, and "made the machine." I got good reports (full quieting) and scratchy reports, but I got out—eight times... Eight different repeaters!

The crowning achievement was making the Topsfield, Massachusetts, repeater—about 70 miles distant and on the *other* side of the mountain behind which my QTH lies. Okay, I'm not going to tell you that the Com-Rad DDRR antenna has to be for *you*. All I can say is that it's going to be *my* antenna for two-meter FM mobile from now on. It's strong, it's easy to tune (covers a range from 143-150 MHz and matches 50-Ohm coax at near unity swr), it has a low profile, it's small (not much larger than a saucer), it works like a bandit, it can be removed or replaced in seconds, and it has *no* mobile flutter. Besides all that, it's, well...er, ah...*gotta* say it...kinda cute, and a sure conversation starter wherever you go.

The price of the CR2A is $39.95 (plus $2 postage) delivered to your door, mag mount included, pretuned to about 146 MHz and matched to 52-Ohm coax. For more information about this and other space-saving antennas, write Jim Waldon at *Com-Rad Industries, 1635 West River Parkway, Grand Island NY 14072.* Reader Service number 477.

ROGO CW SOFTWARE

Over a year ago I read an advertisement in *73* for a Rogo Computer Products program that could run CW on a TRS-80. I was a little skeptical, but at the price offered ($19.95), I wouldn't lose too much if it turned out to be a lemon. I had previously tried several other products that didn't work too well on the Model I.

Response time was very fast; I had the product back in less than a week. I received a tape with the program on one side and a message in Morse code at 30 wpm on side B. The documentation was a ten-page leaflet.

The program has two parts, a machine-language loader and the Basic program. Once the tape is loaded, you type RUN and the machine-language driver is POKED into memory. The program then deletes those lines of the program and returns with a second prompt. You type RUN again and you are now in transmit mode. The program will ask you for CALL, RST, & WPM. You can now access the receive mode by pressing the "*" key and answering the prompt with the estimated receive speed. You can now run your demonstration tape.

Interfacing is really simple and adequate instructions are given. Rogo recommends that you key the transmitter with a keying transistor actuated by the audio out of the cassette port. I key my FT-902DM transceiver this way. You can also key your rig with the TRS-80 internal relay or with an external relay. Again, adequate schematics and information on program changes are given.

The program works almost flawlessly on receive. I have compared it with several other products and I have to say Rogo's works best. I have copied CW at over 100 wpm without any problems. Audio is fed into the audio-in cassette port. They recommend that you adjust your receiver so that the note is about 2200 Hz. The received CW also is stored in memory if you protect memory on initialization. On the upper right corner of the screen, if a character is being stored, it will display the character as it is being put to memory. There is a command that can later recall the stored CW and print it in the screen, output it to a line printer, or resend it as CW. You can clear your buffer at any time. The receive program also prints out on the line printer simultaneously as it is receiving. The program outputs to my Microline-80 printer one line at a time during receive. The program does not look for a busy signal from the printer, so there are no program hang-ups and you do not have to worry if the printer is on or not. I have used the program to copy W1AW bulletins and later print them out. It seems to be very tolerant as to sloppy fists and to speed tolerances. If your speed selected is incorrect, simply hit the ENTER key, the program will tell you the actual speed of the received signal, and you can then enter a new speed.

The transmit program can be sent from either the keyboard or from a selection of messages you can permanently put into your program. All customizing instructions are very complete. You can insert the other station's call and RST on initialization of the beginning of each time you go to the transmit mode and then send it out with one key command. There is a CQ command that sends out CQs, pauses for about 10 seconds, and then calls CQ again until the keyboard is interrupted. The only problem with the transmit program is that you can only type ahead one character. I have used a FIFO utility to create a buffer with limited success.

The program comes in 16K or 32K and can operate on a Model

I or III. The Instructions tell how to convert the 32K program to disk. All In all, it is well worth the money.

For more information, contact *Rogo Computer Products, 4752 DeBeers Dr., El Paso TX 79924.* Reader Service number 478.

PALOMAR SWR AND POWER METER

No matter how you look at it, Palomar Engineering's model M-827 swr and power meter is a unique product and the result of a unique idea...so much so, in fact, that a patent has been applied for.

What can be so different about an swr and power meter, you say? Well, the display, for one thing...LEDs that show both swr and output power simultaneously. These are arranged in two side-by-side vertical columns on the front panel of the meter and light up when rf power (and ac power, too, I must say) is applied. The swr value appears in the left-hand vertical column. The swr scale is logarithmic and is graduated in increments that read from a value of 1:1 up to a value of 10:1, while the output power scale depends upon which range switch can accommodate powers from 0-20 Watts, 0-200 Watts, or 0-2000 Watts, at any frequency between 1 and 30 MHz.

The M-827 is fully automatic, which means that you don't have to set either a *set* or *sensitivity* control when measuring either swr or output power. All you have to do is plug the unit into the house mains (115 volts ac), attach your antenna and transmitter coax, and set the range switch to the peak output power anticipated: 20, 200, or 2000 Watts. A built-in computer automatically sets the full-scale range so that your reading will always be correct. The light-bar, or segmented LED display, is instantaneous, following voice peaks on SSB or keyed characters on CW...meaning that there is no meter lag and permitting continuous monitoring of the essential facts of your transmissions: Are you putting out power, how much, and is your antenna operating normally?

The logarithmic display of swr is useful because at the very low range of swr, the adjustment or tuning of an antenna tuner can be critical, and it is difficult to get those tiny and exact adjustments to ensure a perfect match every time.

For example, I can adjust one of my antennas to read down to as low as 1.02:1 swr. The analog computer and digital comparator in the circuit show exact relationships between output power and swr, meaning that you know at all times just where you are in the antenna and transmitter department. Besides all that, it is plain fun to watch the little red columns fill up or empty as conditions change, and what's more, you can do it in the dark! Maybe I'm one of the few hams who like to operate in the dark, or at least with reduced ambient lighting in the station, but under these conditions conventional metered swr meters and power meters are almost impossible to read. Not so the M-827, which can be seen under virtually all conditions of ambient light from brilliant sunlight to darkness.

The M-827 makes a very nice station accessory, in addition to being useful, because it is also small and attractive. The dimensions of the metel case are 4″ x 4″ x 5″. The top and sides are finished in black vinyl, while the front panel is a neat and conservative brushed aluminum. A power cord for 115-volt, 50/60-Hz ac is furnished (supply built in) and two SO-239 chassis connectors are provided on the back panel, one for input from the transmitter and the other for output to the antenna or to the tuner.

Having owned and used many different types of reflected power meters, I was most anxious to try this new one and to see if it would be compatible with my station and my operating needs. It turned out to be both. I used it to tune and calibrate my new R-3 antenna (report elsewhere this issue) and to measure output power and swr on my other antennas...all of which turned out (thankfully) to have less than 1.5:1 swr. I was also surprised to learn that the output of a popular-brand transceiver that I use is considerably less than what I have been telling hams on the air.

Since the little Palomar swr and power meter works so well, I am looking forward to Palomar's new 300-Watt-range antenna tuner so that I can connect the two and run some experiments on a bunch of different wire antennas that I've had in mind for some time.

Need I mention that due to its small size the M-827 would be an ideal portable companion to take along with your rig to that vacation QTH? That's where mine is going, if I can ever get the time to take a few days off to do some laid-back hamming.

Finally, you don't have to believe everything I say about this little gem from Palomar Engineering. Get one yourself and find out that I wasn't kidding...it's *great*, and I recommend it highly.

For more information, contact *Palomar Engineering, 1924-F W. Mission Rd., Escondido CA 92025.*

LETTERS

ION CHOICE

As a government employee, and therefore one who is often concerned with maintaining a proper office enviroment, I was intrigued by the July, 1982 constuction article on the negative-ion generator. I promptly built one, installing it in a decorative plastic vase (complete with decorative plastic flowers) in my decorative plastic office. It seemed to work, improving the atmosphere around the "salt mine." But all this improved atmosphere seemed to be at odds with the usual need for office dissention, so I modified the design by adding a second generator, wired to generate *positive* ions, with a concealed switch to select between the two. Now, I can have my choice of office environment to match my mood; sweetness and light or hate and discontent, all at the throw of a switch. Technology marches on!

T. Bills KG6JFX/5
NSTL Station MS

"ADMIRAL RICKOVER"

At age 56, I must admit that I sided with the old ham fraternity that the code requirement be kept intact. However, as time goes on I am beginning to see your point of view. Please keep up your aggressive stand to reduce the code requirement as a barrier, and to subsitute a more comprehensive and tougher theory exam. We do need younger folks entering the ham radio field...keen minds that enjoy experimenting and developing. I am afraid this energy is being drained off by interest in computers and video fun and games.

In talking with a ham dealer the other day, I sensed that our lackluster sales of ham equipment is not just the economy, but a need for a spark in the radio field. Two meters gave us that newness some years back and now this interest is fully developed and has hit its plateau. Relaxing the code requirement could bring about this second wave and burst of interest we all need. The ARRL should sense this, looking at the long-range picture, and join forces with you. Only the ARRL can bring about a change of mind in the ranks.

I recall my own interest in electronics, radio, and radar in World War II in the Air Force. All my instructors were hams and my personal interest and knowledge of the subject was the result of a next door ham operator who taught me the fundamentals.

I saw USA military helping to train British radio operators and technicians in World War II because our young folks were more knowledgeable. We need this trained back-up civilian group for the future.

You may well be our "prophet" or our "Admiral Rickover" with a better long-range view than most of us. Unfortunately, many see you as a so-called competitor of *QST* (ARRL) and

your views get clouded because of that situation.

Keep up your stand. You have at least convinced me that your ideas are sound.

Ervin Jackson, Jr. N4BIG
Charlotte NC

73 AUTHORS

In this day and time when everyone is writing to you, chewing you out for one thing or another, and complaining about this and that, I thought I would write you a "happy letter."

I have been a continuous subscriber to *73 Magazine* since 1968 and a charter subscriber to *80 Microcomputing* since the beginning. Your viewpoints, due to your first-hand experience and your age, I have totally agreed with, ever since your days at *CQ*.

Wayne, I don't know what it takes to gather a staff and to put out a magazine, but I'm going to tell you about one person's experience—a person with very limited knowledge and many questions to ask about everything. I have built many, many projects out of the pages of *73*. I have built and tried to understand many things out of *80*. In both cases I must admit that I couldn't have accomplished anything without the kind help of the authors of the articles. I don't know where you get these people, Wayne, but there is not a more dedicated group of people anywhere on this Earth. I don't give a tinker's damn whether I make a mistake on a program or there is a misprint in an article—I always know I can write the author and get help, and so far, over the years, with 100 percent response. Now how do you like them apples?

In years gone by, I have started several expensive projects from the pages of some of the other magazines and when I ran into a problem, I wrote the author. After all, his address is printed along with his name. I got absolutely no response, and this was after letters, telegrams, and phone calls. I even had one *QST* (well-known) author tell me to "go to hell you stupid bastard" when I was paying for the phone call and only wanted a simple question answered. Not so with *73* and *80*. I get only very quick responses, and over the years, have gained new and valuable friends who, after months have gone by, take the time out of their own busy schedules just to drop me a line and find out how I'm doing with their particular program or circuit. Hell, Wayne, what more can a person ask?

The world is in one hell of a mess, and everyone knows it. But there are a lot of dedicated human beings out there, like yourself, who feel a little sorry for the other guy and can take the time to give a helping hand to someone who might not be as well educated as they are or not have the experience that they have. Can you believe all this for the simple outlay of twenty cents and an envelope? Well, I can.

I don't want to take up your time, Wayne, because I know you are busy. I simply wanted to let you know that there are a lot of people out here who appreciate all that you are fighting for, as well as what you stand for, but who may not have the time to write and let you know. If you want to publish this, I would appreciate your not using my name. I don't wish to cause any embarrassment to anyone. Keep up the good work, pal.

Name and
Address Submitted

First nice letter in months and he wants his name withheld for fear of repercussions. Boy, what a fan club I've got!—Wayne.

SURVIVING

After reading the letters "No Nukes I" and "No Nukes II" (*73*, July, 1982), I felt that I ought to add my two cents worth.

The letter writers object to "Surviving the Unthinkable," an article which appeared in the May, 1982, issue of *73*, which suggests EMP-hardening of amateur installations. The writers seem to feel that it is possible to avert a calamity by remaining unprepared. By that reasoning, to prevent fires we should get rid of fire extinguishers and fire departments; to prevent burglaries we should avoid using locks.

The assumption that there would be no survivors after a nuclear detonation must never be used as a starting point for deciding what to do. If you are on a sinking ship, the only constructive strategy is to assume that you *will* survive and to act accordingly. If you go down after all, well that's the way it is. But if you *assume* there is no hope, and you don't do anything to help yourself, then you will go down for sure (and you deserve it).

To be unprepared is to invite trouble. As an example, review the events leading to World War II, especially those of 1939 and 1941. If you are unable to stop them, someone will take advantage of you; examples are the "woodpecker," also broadcasts (sporadically) on 10.000 MHz (jammimg WWV time and frequency-standard transmissions), the Falklands episode, Afghanistan, and others. Someone once said, "Those who don't learn from history are doomed to repeat it."

So, let's pray that a nuclear conflict will never happen. But for heaven's sake, let's not announce to the world that we intend to be unprepared, and that we will give in to anyone who threatens us. If we do, you can bet your bottom dollar someone will.

Hans Schroeder AE9G
Milwaukee WI

10 WPM

I think you fail to recognize the one major advantage of CW. It is the only mode which can be sent and/or received by any combination of equipment, from the most primitive (keyed oscillator/superregen receiver) to the most sophisticated (computer-controlled keyboard and printer). Try copying even the slowest Murray from a pair of cans, or sending ASCII with a straight key, and you will begin to appreciate the universality of CW. What I believe is really needed is a reduction in the code-speed requirement for General and Advanced to 10 wpm. This, besides complying with the International Agreements, eliminates that plateau which discourages so many would-be hams. Anyone who further pursues CW will automatically increase his/her speed, and the others lose their edge anyway so there really is no loss.

As for the Bash books, any good teacher can tell you that there are many ways to reword the same question so that a memorized answer will not suffice. The FCC could easily have a hundred versions of the same exam if they desired. Then these "guides" would be nothing more, just guides. By the way, in case you've been out of college too long, study guides are very useful in that they reduce the nervousness before an exam by proving to you that you *do* know your subject.

George Gray WB2CHP
Spring Valley NY

By George! You're right. All we have to do is get after Reagan and get him to increase the money to the FCC so they can write more tests and frustrate Bash bookers. The recent cuts in FCC funds brought about a severe cut in the amateur radio division... and more cuts are in prospect. Let's get Reagan busy on getting some of the missile money into the ham division of the FCC so we can have better tests. On the code, since polls show that most hams want the code test to stay, let's make the code so it really is the filter everyone wants and will keep out the fruits and nuts. Let's make the Novice code test 35 wpm and the General 45 wpm. Advanced could be moved to 55 wpm and Extra to 75 wpm. Or we could simplify the whole thing by splitting it in the middle and having one speed for all further licenses: 50 wpm. We can cut down on Bash's income by having just one class of license... Extra. That would cut the cost to the FCC, with only one license test to give, and they could spend more time making it difficult.—Wayne.

COMPROMISE

As to the no-code license, there seem to be two schools of thought on the idea, with neither side willing to give an inch. I feel that the "Let's-keep-the-code group" is broken down into two subgroups. One subgroup feels it would ruin amateur radio and the other has the attitude... "I got mine the hard way, let everyone else do the same." I disagree with both subgroups. But, that's not to say either group is entirely wrong.

Why not a compromise? Why not a six- or seven-wpm code test? Who says that thirteen wpm is the magic speed that makes you a licensed amateur and a good ham radio operator? How many operators pass their General test only to put the key away for good? How many Generals could pass a thirteen-wpm test right this moment? Isn't

theory, good operating procedures, and knowledge of all the rules and regulations more important than being able to copy thirteen wpm?

Of course there are a lot of darned good CW operators on the bands and the thought must come to mind that if CW was not a requirement, what would happen to the CW portions of the bands? That is one of the reasons why we should compromise and keep some CW requirements.

I would like to ask the "I-got-mine-the-hard-way subgroup" if they still add and subtract by hand as they were taught in rammar school.

To the subgroup that feels hat it would ruin amateur radio, et me say I see no reason why nowledge of more than six-pm CW would be of any value o operating in the RTTY, SSTV, M, SSB, ATV, or FM modes. If ou feel that the same people ho ruined CB would then move p to ham radio and ruin it, I ould not disagree more. First of ll, most of these people don't ven hold CB licenses, so why would they bother to get an mateur license? Why don't they just move to our bands and perate in the same illegal maner as they are accustomed to in their own bands? What is to top them? A thirteen-wpm code test? I can't buy that.

As to the no-coders (to which belong), let's face reality, it ust isn't going to happen on he HF bands. So why not compromise?

Wayne, as I indicated to you earlier by a copy of my letter to he FCC, I feel that the Technician class should be able to operate in a voice portion of the 10-meter band. I would like to hear comments on that idea as well.

Joseph D. Kelly N2CCV
Wildwood NJ

Joe, we're sure beating this code thing to death with blather. But never mind, I'm still able to imp to my typewriter and write about it. Firstly, six words per minute? Horsefeathers! Apparently you are unaware that the 13-wpm speed was picked with fiendish delight by our long lead torturers. That speed was not picked at random. You see, though we are just in recent years learning how the brain works, the empirical tests showed us that there was a plateau at around ten words per minute. The old-timers didn't know why this was, but they did know that, using the code-learning techniques of 1910, this was a formidable obstacle to learning the code at any reasonable speed. So naturally they set the speed required for a ham ticket just above this plateau. Before they pulled this beaut the code speed for a ham ticket was 10 wpm and few people had much trouble with that. The 13 wpm weeded out 90% of those trying for the license... a much more satisfactory situation for the old-timers interested in keeping the bands from getting too crowded.

We now know that the old-fashioned code-learning system called for one side of the brain to set up a look-up table (to use computer terms). The other side of the brain received the signal, sent it over to the other hemisphere where it was checked against the table, and the resulting letter found, this message was sent back so it could be written down. The problem came when the speed of transmission of the brain was reached... at around ten words per minute. Beyond that the brain could not look up the characters fast enough and frustrations set in which usually resulted in the candidate giving up.

The brain had to respond by giving up that whole method of translation of the sound patterns and throwing away both the look-up table and the oscillation of the information back and forth between the two halves of the brain.

Now we know that what happened was that the brain set up a whole new system whereby the sound patterns were equated to the writing of the letter or the typing of the letter, without the problem ever having to be referred to the other part of the brain. This is done on a subconscious level and is quite automatic. This is why good code ops are able to sit and talk with you while copying code. They don't have to listen on a conscious basis at all.

Now, in order to get code learned using this system of brain work, it is necessary to develop the automatic process. Modern code-teaching systems start out with code at 13 wpm, which keeps the look-up table syndrome out of the picture. They space the sounds to give the brain time to set up the translation patterns... not to tell you what the characters are one by one, but to cause your fingers to write them. The brain adapts to the sound patterns quickly with this approach.

Obviously, if you are going to go up to 20 wpm for the Extra-class license, you don't want to gradually speed up the code, you want to change immediately to 20 wpm and retrain the subconscious to recognize the new sound patterns... and write the letters. This is why people using this system of learning are able, in many cases, to start right in at 20 wpm and, within a couple of days, be copying away.

You know, I've tried to get the League to stop using the 1910 code-teaching system for almost 20 years. I eventually gave up and put out my own code tapes. Suddenly, thousands of people who had virtually given up on ever passing the code test found out that it was duck soup. I'll bet I've had over ten thousand hams tell me that my code tapes got 'em through... often after repeated failures with other systems.

Okay, so much for that. My apologies to readers who have been through that story before, but for some reason it always seems to be news to some.

The enthusiasm of many hams for CW and their insistence on all newcomers having to pass a code test as a way to ensure that they will enjoy code is, at best, faulty psychology. People don't work that way. Hells bells, I enjoy RTTY, but I know that if I try to force people to learn about it they are going to react the way any rational person does: they are going to resent being forced. No, if we made CW use a matter of pride rather than something our government forces us to do, I know that we would have a lot of CW enthusiasts.

The people of Russia and China may have gotten used to slavery, but we here in America haven't. Look at the resistance to the draft... which qualifies, I think, as slavery. It looks to me as if the CW fans have been doing the one thing which has most resulted in what they don't want: forcing people to learn the code resulting in antipathy to it.

Techs on ten meters? Sure, as soon as you get rid of the code as an element required for the General license.—Wayne.

SILVER PLATTERS

For the past six months I have been reading a lot of letters from readers concerning the no-code licensing. Our country is already burdened with give-away programs such as welfare. Now we have advocates of give-away amateur radio licenses.

I don't work a lot of CW, but I am one of the few people in this country who believes you don't get something for nothing. Do you get a medical or law degree, or even a high school diploma without having to learn some things that you may never use? No you don't, but as with the no-code licensing advocates there are probably those who would like give-away high school and college degrees. The problem is that too many people want to do away with requirements that keep them from taking the short cut.

The requirement for learning the electronic theory has already been done away with by Bash Publications, and now there are those who want to do away with the code test. As it now stands the only thing that keeps many from getting their amateur licenses is that they are too lazy to learn the code. Why don't we do away with the Dick Bash cheat sheets and keep the code test?

If the rules are not followed prior to getting on the air then what will happen after these people get their tickets? I suspect that these same individuals will break the rules and cut the corners after they have gotten on the air as they did prior to getting on the air. This is already occurring on the 2m bands in some of our larger cities.

In conclusion, I would like to say that if you don't want to work for what you want, then get your checkbook out and go to your local department store and buy a CB. All you need to do is fill out the form that is enclosed with the CB, send it to the FCC, and you are on the air. You will be right at home with the rest of your kind. I am not saying that all CBers feel that way, but I started out on the CB band and I knew what I wanted so I worked for my license. You can't get through life expecting everything to be given to you on a silver platter just because you don't want to pay the price. Let's all hope that amateur radio li-

censes are not handed to the same individuals on silver platters.

Jerry Leckness KD4XR
Tuscaloosa AL

Jerry, you either don't read carefully or else you have poor retention. You also have one hell of a negative attitude, for you had not one single positive suggestion about solving the problem of getting good hams. And I can't take your beef about the Bash books seriously until I see a copy of a letter from you asking CQ not to run his ads...or a letter to a ham dealer saying you're not going to buy from him as long as he sells those books. I have yet to hear of one single case where any ham has gone into a dealer and torn up the Bash books on display...not one. No, 100% of the hams have accepted this flagrant poisoning of our hobby. Not one single ham club in the country has taken a stand against Bash, so I must assume that 100% of the hams don't give a damn whether or not any newcomers have any technical knowledge...and that includes you, Jerry. Ham licenses are being handed out on silver platters and I don't see you doing anything but griping. The code doesn't prove anything. Some people can learn 20 wpm in a weekend, others can struggle for months and not get 5 wpm...that's a matter of chance and genes.—Wayne.

DIGITAL CODE

The FCC is doing ham radio amateurs a great injustice by not replacing the Morse code with a more viable alternative and by being reluctant to introduce computer technology into ham radio.

The Morse code, being a good base for communications, is at present outdated and not in step with our current technology. It remains for many a nostalgic foothold with the past—a good feeling of taking part in something that originated in past history. However, Morse code does not a true amateur make! There are many good hams around that had (and still have) the darnedest time learning the code to get their licenses. And then there are many code experts who are not good hams at all. There are also good hams who are good at code. A true ham radio amateur is one who has the proper spirit, attitude, and dedication to radio communications, no matter what the method used to communicate or the kind of ham gear used. There are many would-be amateurs who have the proper attitude but have a hard time getting their ticket because they cannot feel the rhythm of Morse code. This is akin to the person who either likes or dislikes classical, jazz, pop, or folk music. In many cases it means you either have it or you don't. This is very unfair to a true radio amateur.

As an alternative to Morse code, I would propose the FCC adopt a digital code. An exam would be given in two parts. In part A, the applicant would have to prove mechanical and proper operation of a basic keyboard encoder-decoder. In part B, the applicant would be given a test on digital-code theory to show understanding of what makes it work. This is not difficult and has its roots in Morse code basics—an on-off switch. As for buying the equipment, there are many economical systems now available, and by the time the FCC adopts such a resolution, prices would drop further.

As for computers and ham radio, it is the only way to go. It is not true that the human touch would be gone with computers, as many feel. Once again this is a vestige from the past. In contrast, the computer can allow the ham more room for human expression. An alphanumeric keyboard has limitless possibilities for personal touch communications. Those who criticize the computer don't understand its operation, don't own one, or don't know anyone who owns one and knows what it's all about. After all, a computer is nothing more than an off-on switch, the number of switches related to its capacity or memory, and the switching done electronically. In fact, a Morse-code keyer is a basic computer. So hams have been using computers for years, but they don't know it.

Roger E. Berube
Nashua NH

TERMINALL

apple* + TRS-80*

TERMINALL is a hardware and software system that converts your personal computer into a state of the art communications terminal. Terminall features simple connections to your computer and radio plus sophisticated and reliable software.

Simplicity

TERMINALL was designed from the outset to be easy to connect to your radio and easy to use. Plug into your receiver headphone jack and copy Morse Code or radioteletype (RTTY). Plug into your CW key jack and send Morse Code. Attach a microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.

The software is loaded into your computer from disk or cassette. Enter your callsign and the time and you will start receiving immediately. No settings or adjustments are necessary to receive Morse Code, it's fully automatic, and it works! You may type your message while receiving or transmitting.

You will be on the air, receiving and transmitting in any mode, in minutes. As we said, TERMINALL is simple.

More for your money.

■ TERMINALL has the RTTY terminal unit (demod and AFSK) built in. This results in a lower total cost.

■ **Fantastic Morse reception.** Six stage active filter demodulator copies the weak ones. Auto adaptive Morse algorithm copies the sloppy ones. Received code speed displayed on status line.

■ **Outstanding documentation.** Professionally written, 90 page user manual contains step-by-step instructions.

■ **Built in, separate, multi-stage, active filter RTTY and CW demodulators.** No phase lock loops. RTTY demodulator has 170 and either 425 or 850 Hz shift (keyboard selectable) and uses either the panel meter or scope outputs for easy tuning. Copy the weak ones. Copy the noisy ones. Copy the fading ones.

■ **Built in crystal controlled AFSK.** Rock stable for even the most demanding VHF or HF applications. A must on many VHF RTTY repeaters.

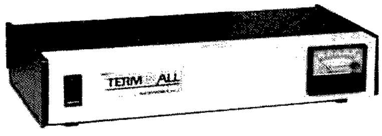
■ **Built in 110 or 220** volt AC power supply.

■ **Built in parallel printer driver software.** Simply attach a parallel ASCII printer (e.g. the EPSON MX 80) to your printer port to obtain hardcopy in all modes.

■ **Multi level displays** allows examining and editing of historical text.

■ **Word wrapping,** word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, multiple user defined WRU, transmit delay (fixed, none or auto adaptive), break mode and more!

■ **The all-in-one TERMINALL design** makes it great for use on HF or VHF, Ham, Commercial, SWL or MARS! SWL's TERMINALL may be jumpered for either 425 or 850 Hz reception to copy news and weather services.



System Requirements

TERMINALL T1 Communications terminal for the TRS-80 Model I. Requires a Model I TRS-80, 16K RAM and Level II BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T3 Communications terminal for the TRS-80 Model III. Requires a Model III TRS-80, 16K RAM and Model III BASIC. Includes software on cassette and disk, assembled and tested hardware and an extensive instruction manual. **$499.**

TERMINALL T2 Communications terminal for the APPLE II. Requires an APPLE II or APPLE II PLus with 48K RAM and disk. Software is provided on disk in DOS 3.2 format. Use MUFFIN utility to convert to DOS 3.3 format. Includes software on disk, assembled and tested hardware and an extensive instruction manual. **$499.**

NEW PRODUCTS

OSCILLOSCOPE MULTIPLEXER

Global Specialties Corporation has introduced an oscilloscope multiplexer that extends the capability of any oscilloscope from one to two input channels to eight, permitting a direct comparison of simultaneous events.

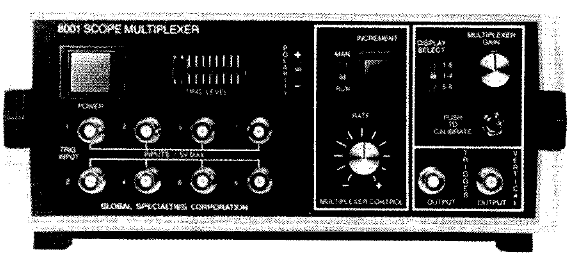
The model 8001 multiplexer accepts signals of ±8 volts (10 volts peak-to-peak) through eight BNC connectors and provides a flat frequency response to 12 MHz and only −3 dB at 20 MHz. Input impedance is 1 megohm.

The user can view all eight channels at once, or either of two four-channel combinations: 1-4 or 5-8. Once the overall relationship of input signals is observed, the operator may zero in on a particular signal by using the manual mode of operation and then using the increment switch to select the desired input signal (channel).

In use, the trigger signal is connected to channel 1, where its polarity may be switched and its level varied over the ±5-volt range. A "push-to-calibrate" button zeros all channels for scope calibration, leaving only the vertical display gain to be adjusted.

The model 8001 oscilloscope multiplexer can be used for field service of electronic equipment, for monitoring several signals at once, for looking at families of data originating from different sources, and for many other purposes. Suggested retail price of the model 8001 is $349.50.

For additional information, write *Global Specialties Corporation, 70 Fulton Terrace, New Haven CT 06509-1942.*



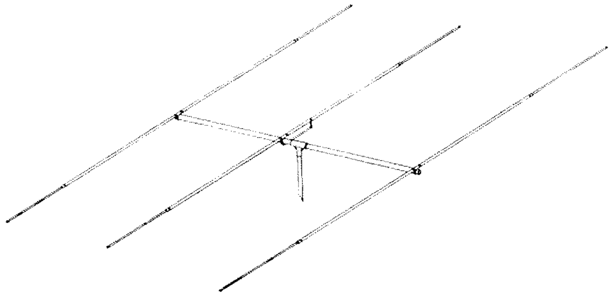
Global Specialties Corporation's oscilloscope multiplexer.

HUSTLER ANTENNAS

If six-meter operation is your dish, you will be interested in three new antennas recently introduced by Hustler, Inc. The 6-MB3 three-element yagi features a 6-dB forward gain while maintaining a front-to-back ratio of 28 dB. Bandwidth for a vswr of less than 2:1 is 2 MHz, and at resonance centered on 50.1 MHz, the vswr is under 1.2:1. The suggested retail price is $69.95.

Model G-3754 is a vertical, endfed collinear, omnidirectional antenna for fixed station use, and is ideal for repeater applications. Bandwidth for a vswr of under 2:1 is 1 MHz and, at resonance, is 1.2:1.

Hustler's endfed collinear.



Hustler's 3-element yagi.

Gain is 3.4 dB, developed from a .65 wavelength radiator. The SRP is $89.95.

The G-3754 and 6-MB3 are constructed of high-grade seamless aluminum tubing and stainless steel hardware for durability and long life.

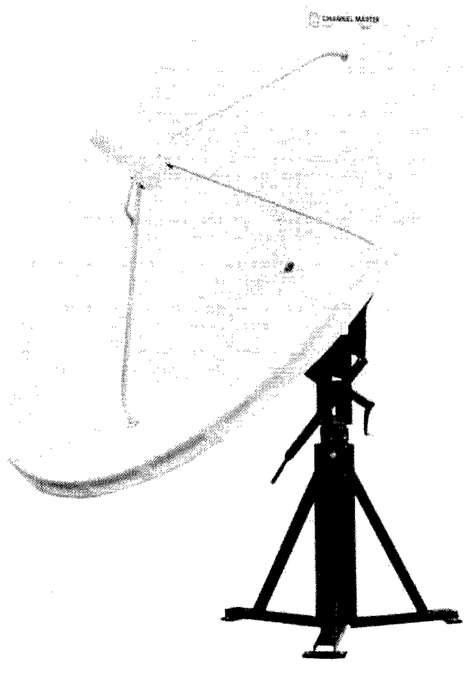
For mobile use, the new BBL-4554 base-loaded antenna is 48 inches in overall height and is shunt-fed, providing optimum performance on FM, AM, or SSB. The antenna is supplied complete with stainless steel impact spring, ¾-inch hole mount, and 17 feet of RG-58/U coaxial cable with PL-259 connector installed. SRP is $39.95.

For further information, contact *Hustler, Inc., 3275 North B Avenue, Kissimmee FL 32741.*

CHANNEL MASTER EARTH STATIONS

A new feed assembly used in Channel Master's new generation Earth stations features a 120° or 100° LNA (low noise amplifier), scaler feed, and automatic polarizer. The LNA offers weather protection and reliability with a one-piece cast aluminum housing that is coated with a weather-resistant urethane finish. In addition, the lid is sealed with an elastomeric "O" ring for weather-tightness in an unprotected environment.

The scaler feed features re-



Channel Master TVRO Earth station.

duced spillover for minimum interference and noise pickup and gives .5-dB-gain improvement over conventional rectangular feeds. For optimum dish performance and ease of installation, the unit is factory pre-calibrated to the exact focal length from the reflector.

Waveguide-coupled to the LNA, the integral feed polarizer makes possible convenient dual-polarity reception and eliminates the need for complicated feed rotation or expensive double LNAs. The probe automatically assumes the correct position for any channel selected by the receiver, without additional polarity adjustments.

The turnkey system complete with 12-foot dish is $5295; with a 10-foot dish, $4995.

For further information, contact *Channel Master, Division of Avnet, Inc., Ellenville NY 12428; (914)-647-5000.* Reader Service number 483.

KALGLO'S SURGE SUPPRESSORS

Kalglo Electronics Company, Inc., has added a new Quad series to its line of surge suppressors designed to protect sensitive electronic equipment from damaging power-line transients, high-voltage surges, and electrical noise interference conducted along ac lines.

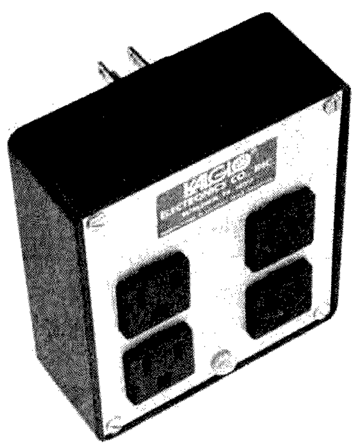
Quad surge suppressors have four filtered outlets, which take care of computers which need more than two filtered outlets (such as the Apple, for example). The Quad-I has transient absorption only, while the Quad-II has transient absorption plus dual 3-stage low-pass filters for RFI "hash" filtering.

All units are prewired and ready to use. For more information, contact *Kalglo Electronics Company, Inc., Department Quad, 6584 Ruch Road, East Allen Township, Bethlehem PA 18017.* Reader Service number 486.

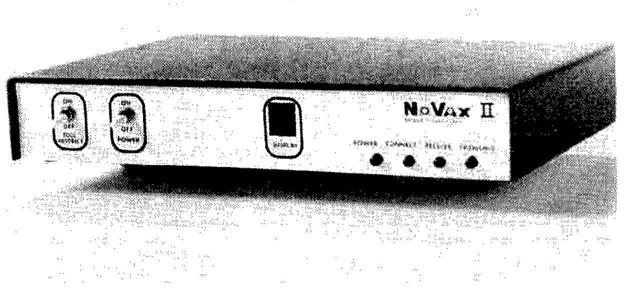
THE CES 635 MICRODIALER

Communications Electronics Specialties announces their new CES 635 Microdialer, designed to make life easier for the mobile radio operator. The 635 incorporates the microphone element and the keypad buttons on the *same side* of the microphone, enabling the mobile operator to put through an autopatch call without ever taking his eyes off the road.

The CES 635 Microdialer.



Kalglo's plug-in surge suppressor.



Current Development Corporation's Novax II mobile connection.

The Microdialer features a programmable pause that allows the operator to bring up the patch, pause, and dial the telephone number by pushing two buttons. It also keys the PTT line prior to sending the first tone so that nothing is lost in the transmission.

The first five memories hold up to eleven digits, and memories six through zero hold up to seven digits. Dialing speeds from one to eight digits per second can be programmed as desired.

The suggested retail price is $99.95. For additional information, contact *Communications Electronics Specialities, Inc., PO Box 507, Winter Park FL 32790.* Reader Service number 485.

NOVAX II MOBILE CONNECTION

Current Development Corporation (formerly R.W.D., Inc.) announces its new Novax II Mobile Connection for interfacing with DTMF (TouchTone®) and rotary-dial telephones. In addition to the standard features provided by Novax I, Novax II offers: 4-digit access code, LED display, toll restrict, repeater use, and rotary-dial-interface capability. Both units employ high-speed switching techniques, eliminating voice-activated switching problems.

Suggested retail prices are: the base unit, $279.95; the rotary module, $49.95, and the ringback module, $39.95.

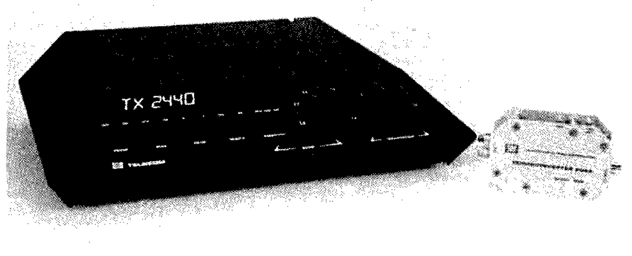
For more information, contact *Current Development Corporation, Box 162, Tudman Road, Westmoreland NY 13490.* Reader Service number 484.

SATELLITE EARTH-STATION RECEIVER SYSTEM

Telecom Industries Corporation has just announced their new TX-2440 satellite Earth-station receiver system. The receiver incorporates several unique features, including a three-position audio-subcarrier bandwidth selector, and an LNA-mounted, dual-conversion downconverter (patent pending) that enables any LNA to be converted to an LNC in seconds. The TX-2440 lists for $895. For additional information, contact *Telecom Industries Corporation, 27 Bonaventure Drive, San Jose CA 95134.* Reader Service number 491.

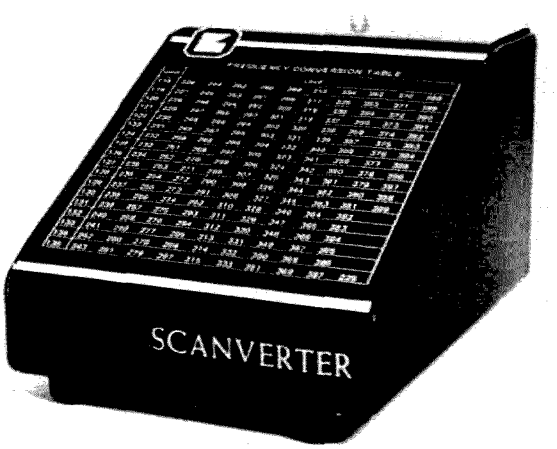
RIDGE SYSTEMS RTTY INTERFACE

Ridge Systems Co., Inc., has



Telecom Industries' new TX-2440 satellite Earth-station receiver system.

RTTY interface for the TRS-80 color computer, by Ridge Systems.



The Grove Enterprises 225-400-MHz scanner converter.

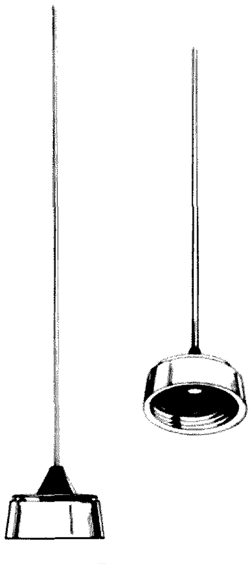
announced the model 4511 RTTY interface for the TRS-80™ color computer. The interface plugs into the Program Pak™ slot and contains all the software and hardware in a ROM cartridge. The five-pin DIN plug on the back of the cartridge provides the EIA signal connections to your terminal unit. Operating features include keyboard control of the message and operating buffers, transmitter on-off, station identification, and 110-baud-ASCII or 60-wpm-baudot mode selection. The split screen simultaneously displays text being entered, messages being received, and system status. Further, the interface firmware supports a printer and selective calling that automatically stores the incoming message on cassette tape.

The interface is designed to be reliable and easy to use. An internal buffer makes operation easier by allowing simultaneous text reception and text entry from the keyboard or permitting one to save incoming text for later re-transmission. The cassette tape permits you to save important or frequently-used messages and reload them as needed. The instruction manual describes installation and use of the interface and contains a schematic diagram, parts locator, maintenance data, and information on selected subroutines. $169.95 includes interface, manual, and 90-day warranty.

For more information, contact *Ridge Systems Co., Inc., PO Box 772, Acton MA 01720; (617)-264-4251.* Reader Service number 489.

MULTIBAND QUARTER-WAVE ANTENNA

Larsen Antennas has introduced the NMOQ special quarter-wave antenna which makes it unnecessary to stock a different antenna for each band.



The Larsen Electronics NMOQ quarter-wave antenna.

The NMOQ adapts one antenna for a full range of frequencies from 136 to 512 MHz. Just cut the rod to the desired frequency.

With a suggested retail price of $7.97, the Larsen NMOQ uses a chrome mounting nut and a silver-plated contact attached to the rod with a set screw. The silver-plated contact has less resistance than the stainless-steel rod and ensures a low resistance rf connection.

Two models are available. Order the complete antenna to fit the NMO mounting hardware, or the NMOQ Special W for the antenna without the chrome mounting nut. For more information, contact *Larsen Antennas, PO Box 1799, 11611 NE 50th Avenue, Vancouver WA 98668.* Reader Service number 488.

THE GROVE ENTERPRISES SCANNER CONVERTER

Grove Enterprises has just announced a new 225-400-MHz scanner converter, the Scanverter CVR-1, which will allow complete coverage of the 225-400-MHz military/federal government aircraft band when used with a standard aircraft band scanner.

Scanverter CRV-1 makes it possible to listen to NASA space-shuttle radio links to Earth, military air tactical war games, Coast Guard search and rescue missions, FLEETSAT-COM military satellites, federal government agencies in flight, and more.

A new development called "bandstacking" allows the entire 175-MHz-wide UHF aircraft band to be compressed into the 118-136-MHz range that is tunable on any scanner capable of standard VHF aircraft-band reception. No tuning or adjustments are necessary with the fully-automatic CVR-1.

Standard features of the Scanverter include: a high-sensitivity, low-noise microstripline circuit, an all-metal cabinet for superior shielding, a frequency-conversion chart printed on the cabinet, a double-balanced mixer for reduced images, an eleven-pole filter for suppression of out-of-band interference, a crystal oscillator for high stability, and a zener-diode voltage regulator for limiting drift. A power cord for connection to a 12-volt dc supply (not furnished) and an interconnect cable for connecting the CVR-1 to your aircraft-band scanner are also furnished. Suggested retail price is $99.95.

For more information, write *Grove Enterprises, Brasstown NC 28902.* Reader Service number 487.

TWIN OAKS ASSOCIATES' CW TEACHING SYSTEMS

Twin Oaks Associates is a partnership of mental health professionals who are hams interested in helping others to learn CW. Twin Oaks has developed three Morse code teaching systems on tape which represent the careful application of

psychological principles to learning. They help students learn to recognize and copy Morse characters at a very high speed.

The first set of tapes is called System 12©. It is designed for the ham who may have a Novice or Technician class license but can't "get over the hump" to pass the General class code test. System 12 takes students past 15 words per minute on five carefully-structured, successive-demand, 60-minute cassettes.

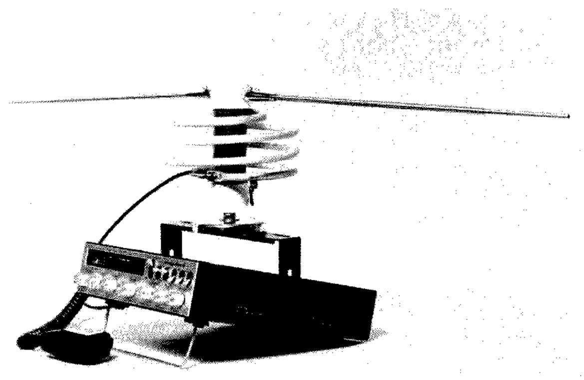
The second training program is called System 24©. It assumes that the student is able to copy comfortably at 9 or 10 words per minute but would like to go after the amateur Extra class license. This program is on five 60-minute cassettes and carries the student past 30 words per minute.

The third teaching system, the System 12 Alphabet Book©, is designed for persons who know absolutely nothing about Morse code. It may be used, however, by persons who are not thoroughly comfortable at 5 words per minute, and it is useful for either classroom or self-instruction.

Each program, or system, comes with its own carefully-written study guide. Systems 12 and 24 cost $30 each, and the System 12 Alphabet Book costs $15.

For more information, write *Twin Oaks Associates, Route 5, Box 37, Knoxville IA 50138.* Reader Service number 482.

COM-RAD INDUSTRIES ANTENNAS



A Com-Rad Industries' space-saving antenna.

Com-Rad Industries has just announced the availability of two new antennas in its line of space-saving antennas for fixed and mobile amateur radio operators.

The CR-1011A and CR-6A cover the amateur 10- and 6-meter bands, respectively. Each antenna is a full-sized quarter-wave vertical groundplane that has been rearranged mechanically to be only 5% of its normal height. It consists of a basic helic element with an adjustable telescoping capacity hat/tuning ring for resonating the antenna to the desired frequency.

Each antenna is constructed of stainless-steel hardware, aluminum helix elements, stainless-steel telescoping capacity hat, and corrosion-proof support structure.

The CR-1011A provides a low-vswr match to 50-Ohm coaxial cable over any preselected 400-kHz segment of the 10-meter band, and the CR-6A provides a low-vswr match to 50-ohm coaxial cable over any preselected 700-kHz segment of the 6-meter band.

For price information and further details about these and other antennas, contact *Com-Rad Industries, 1635 West River Parkway, Grand Island NY 14072.* Reader Service number 490.

FUN!

John Edwards KI2U
78-56 86th Street
Glendale NY 11385

LOGIC TIME

You know, time really does fly when you're having FUN! I can hardly believe it, but this month marks the second anniversary of the FUN! column. That's a lot of riddles and puzzles under the bridge, but it's been a gas. If you've had fun solving the quizzlers presented here, just remember that I've had even more fun creating them. So much fun, in fact, that it feels almost dishonest to take the money Wayne offers—but I really don't have much of a conscience.

I hope you'll enjoy this month's offering: some logic puzzles.

ELEMENT 1—MARC'S CONTEST

During a 24-hour contest, Marc can average two contacts per minute from noon to midnight and six contacts per minute from midnight to noon.

How many contacts will Marc average for the entire contest?

ELEMENT 2—THE DX QSO

A QSO on 20 meters the other night found four hams enjoying an international roundtable. All four operators were of different nationalities and although each could speak two of the four languages—English, French, German, and Spanish—there was no common tongue by which they could all communicate. Complicating matters even further, only one of the languages was spoken by more than two of the amateurs.

None of the hams spoke both German and French.

While Vic couldn't speak English, he acted as a translator for Carl and Dave.

Vic, Carl, and Larry didn't all speak the same language.

Dave could speak German, and rag-chewed with Larry, but Larry could not speak German.

Name the pairs of languages each ham spoke.

ELEMENT 3—COFFEE AND DONUTS AND MURDER

Four hams were standing together after a meeting of the Skunkville ARC enjoying the club's complimentary "coffee and donuts." Suddenly, one of the hams collapsed, moaned "I've been poisoned," and died. His fellow amateurs were arrested and made the following statements under intense questioning (one of the statements is false):

Hertz: I didn't poison him.
I was standing next to Farad.
We had the regular man buy the coffee and donuts.

Ohm: We had a new guy buy the coffee and donuts.
I was standing across from Watt.
The guy who bought the coffee and donuts didn't do it.

Farad: Hertz is a liar. We had a new guy buy the coffee and donuts tonight.
This new guy poisoned Watt.
Ohm is innocent.

Name the murderer.

ELEMENT 4—THE FRIENDLY REPEATER

Repeater station WA2DCS/R has some very touchy users. For instance, five members, whose first names are Harvey, Wally, Steve, Dick, and Stan, and whose last names in no particular order are Tracy, Walters, James, Phillips, and Lewis, have had so many arguments over the years that they will talk to each other only under the following conditions:

Walters will speak to only two of the others.

Phillips and Wally won't talk, but Steve and Lewis will.

Stan will speak to all but one. Harvey will speak only to one of the others.

There's only one out of the group that Tracy won't speak to.

There's only one out of the group that James will speak to.

Wally, Steve, and Dick all will talk with each other.

Give each ham's full name and the names of the other repeater users he will talk to.

ELEMENT 5—THE DXPEDITION

Four men set out on a DXpedition to put the Atlantic Ocean Isle of Long in the logbooks of amateurs around the world. Each of the men was employed in a different line of work than the others. There was an engineer, a stockbroker, an author, and an airline captain—and their names, in no particular order, were Steve, John, Doug, and Bob.

John is older than Steve.

The author and the airline pilot are brothers.

John is Doug's nephew.

The engineer had no relatives on the DXpedition.

The airline pilot is not the stockbroker's uncle, and the stockbroker is not the author's uncle.

What is each ham's job, and how are these guys related?

ELEMENT 6—THE TRAFFIC HANDLERS

Four Advanced-class operators and three General-class operators handle as much traffic in five days as three Advanced-class operators and five General-class operators do in four days.

Which class of operators is more productive?

THE ANSWERS

Element 1:
Three contacts per minute.

Element 2:
Vic spoke Spanish and French. Dave spoke Spanish and German. Carl spoke English and French. Larry spoke Spanish and English.

Element 3:
Farad is the killer.

Element 4:
The full names are: Steve Tracy, Wally Walters, Harvey James, Stan Phillips, and Dick Lewis. Tracy will talk to Walters, Phillips, and Lewis. Walters will speak only to Tracy and Lewis. James speaks to Phillips, while Phillips will talk only to Tracy, James, and Lewis. Lewis talks only to Tracy, Walters, and Phillips.

Element 5:
Steve is the engineer. John is a stockbroker. Doug is an author. Bob is the airline pilot. John is Bob's son and Doug's nephew. Bob and Doug are brothers.

Element 6:
The General-class operators.

SCORING

Each element is worth seventeen points. "Logic is logic. That's all I say."—Oliver Wendell Holmes.

1-20 points—Not rational
21-40 points—Semi-rational
41-60 points—With a ration of rationality
61-80 points—Rationalist
81-100+ points—Very smart

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CALIFORNIA QSO PARTY

Starts: 1600 GMT October 2
Ends: 2159 GMT October 3

Sponsored by the Northern California Contest Club, with strong efforts being made to have all 58 counties in California on for the contest duration.

Single-operator stations may operate only 24 hours of the contest period; off times must be clearly marked in the log. Multi-operator stations may operate the full 30 hours. Stations may be worked only once per mode per band. All contacts must be simplex. All CW contacts must be made in the CW subband. California stations that change counties are considered to be new stations and may be contacted again for points credit.

EXCHANGE:

California stations send QSO number and county. Others send QSO number and state, province, or ARRL country.

FREQUENCIES:

Novice—3725, 7125, 21125, 28125.
CW—1805, 3560, 7060, 14060, 21060, 28060.
SSB—1815, 3895, 7230, 14280, 21365, 28560.

Try CW on the half hour and 160 meters at 0500.

SCORING:

Each completed phone contact is worth 2 QSO points. Each completed CW contact is worth 3 QSO points. For multiplier, California stations use the number of states, VO/VE 1-7, and VY1/VE8 for a possible of 58. Others, use the number of California counties worked for a possible total of 58. The final score is the number of QSO points multiplied by the total number of multipliers.

AWARDS:

Certificates for highest-scoring station in each California county, each state/province, and each country. Certificates also to each station scoring 100 or more QSOs. Trophies to the highest-scoring out-of-state single operator, highest-scoring California single operator, and highest-scoring DXpedition to a California county.

ENTRIES:

All logs and summary sheets must be sent by November 1st to: NCCC, c/o Kip Edwards W6SZN, 1928 Hillman Ave., Belmont CA 94002. Please include an SASE with your entry.

GARTG WORLDWIDE SSTV CONTEST PART 2

Starts: 0600 GMT October 9
Ends: 0600 GMT October 10

This is the second part of a two-part contest—the first weekend was in April but rules were received too late for publication. The contest is sponsored by the German Amateur Teleprinter Group (GARTG). A 6-hour nonoperating time must be taken at any time during the contest. Use 80- through 10-meter amateur bands, SSTV mode exclusively. The same station can be worked only once per band. Operating categories include: a) SSTV transmitting and receiving stations and b) SSTV receiving stations (SWLs).

EXCHANGE:

Callsign, RST, message number as three-figure group starting with 001, and GARTG membership number as 5-figure group.

SCORING:

Score 1 point for all SSTV contacts on 80 through 20 meters, 2 points on 15 meters, and 5 points on 10 meters. Multipliers are each country of WAE and ARRL lists, including KL7 and KH6. Each W/K, JA, PY, VE/VO, and VK district will be considered as a separate country. The same continents and countries are valid only once on each band. Final score is QSO points times countries worked times continents. To this score add a 50-point bonus for each GARTG member worked.

ENTRIES:

Logs to contain date/time in GMT, callsign of station worked, RST and message number sent, RST and number received, and points claimed. Don't forget to list the GARTG membership numbers as bonus points! Logs from SWLs must contain both the full report sent and received by the station logged. Incomplete loggings are not eligible for scoring. A summary sheet should show the full scoring and please use separate sheets for each band. All logs must be received within 2 months of the contest and should be addressed to: Wolfgang Punjer DL8VX, PO Box 90 11 30, D-2100 Hamburg 90, Federal Republic of Germany. A free 12-month subscription to *RTTY*, the official organ of GARTG, will be sent to the 3 top scorers of group A.

JAMBOREE-ON-THE-AIR

Starts: 0001 GMT October 16
Ends: 2400 GMT October 17

It's Jamboree time again! Time for Scouts, former Scouts, and anyone interested, to meet on the air for a weekend of good Scout talk. It gives amateurs and Scouts worldwide a chance to listen to or talk with other Scouts. In some cases,

QSL OF THE MONTH: W7ILN

David F. Rollins of Las Vegas has the winning QSL this month. The idea is really novel. The basic design (shown here) is desert flora set off against a desert background. David colors the card with colored pens, and no two cards are exactly alike. The textured paper makes the color have "depth"—the color card David sent in is really superb.

If you would like to enter our QSL card contest, put your QSL card *in an envelope*, along with your choice of a book from *73*'s Radio Bookshop, and send it to *73 Magazine*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries which do not use an envelope or do not specify a book will not be considered.

SPLATTER!

NEWSLETTER OF THE MONTH

This month's winner is *Splatter*, the publication of the Radio Society of Bermuda. The newsletter is published in Hamilton, Bermuda. In addition to the usual club minutes, etc., the May issue had some interesting technical articles and an article on the world's biggest church, which was built by mistake. It seems that the architect's specifications were in feet, but the church was built in meters. *Splatter* also has a letter from the President of the Bermuda Radio Society with his comments on the proposed US phone band extension. In the news briefs departments, there is a note that the VP9 amateurs do not yet have approval to use the 10-MHz band. Although Bermuda is under the British flag, the amateur license structure in the colony is such that special approval is needed before new bands are authorized. Ah, bureaucracy.

Splatter has consistently good layout and its articles are always written in clear, concise language. A pair of charts, one each for resistors and capacitors, is included. The RSB announces their competitions in the newsletter and includes the appropriate forms, ensuring that all the members receive them in time. Cartoons and good drawings are in every issue, contributing to an overall outstanding newsletter.

The newsletter contest is enjoyed by us here at *73*, in spite of the work involved. We encourage all ham radio clubs in the US and overseas to send us a copy of their newsletter every month. We also like to get specialty newsletters such as those for VHF, DX, SSTV, RTTY, and so forth. There is always an array of outstanding newsletters. The competition is always close, so if your newsletter did not win this month, next month may be your turn.

where equipment is available for slow-scan television, to see them also. By the way, this also includes Girl Scouts, Guides, and all Scout leaders.

Look for stations at camporees and other Scout events and for K2BSA, the national headquarters amateur radio club station, and HB9S, the World Scout Bureau station.

Most operations will occur during the period of 0001 GMT Saturday to 2400 GMT Sunday, but since this is not a contest, operations may start Friday and go into Monday. No required contact format, no specific exchange, just Scouting fun. All operations must, however, adhere to FCC rules and regulations.

FREQUENCIES:

Scout frequencies published by the World Bureau are as follows:

Phone—3940, 7240, 14290, 21360, 51150.

CW—3590, 7030, 14070, 21140, 28190.

SSTV and RTTY on usual frequencies.

Post-card-size certificates issued by the World Bureau are available from JOTA Coordinator, Harry Harchar W2GND, 216 Maxwell Avenue, Hightstown NJ 08520, for anyone participating. Send one SASE with sufficient return postage—one ounce per eight cards. They may be requested before the JOTA weekend for distribution then, or for award at Scout Courts of Honor or other meetings.

Logs or lists of participants are *not required*, but reports of activity and photos are welcome for inclusion in the BSA report to the World Bureau and possible use in Scout publications. Send them to the JOTA Coordinator mentioned above.

PENNSYLVANIA QSO PARTY

1700 GMT Oct 16 to 0400 GMT Oct 17
1300 GMT Oct 17 to 2200 GMT Oct 17

Sponsored by the Nittany Amateur Radio Club, this is the 25th annual event. Stations may be worked once per mode (phone and CW) on each band. Mobiles may be reworked as they change counties. Repeater contacts are not permitted.

EXCHANGE:

RS(T), 3-digit sequential serial number, and ARRL section or Pennsylvania county. Stations on county lines will give out one number but the two counties will count as two separate multipliers.

FREQUENCIES:

SSB—3980, 7280, 14280, 21380, 28580.

CW—40 kHz up from bottom of CW bands.

Novice—10 kHz up from bottom of Novice subbands.

SCORING:

Count 1 point for SSB QSOs, 1.5 points for CW QSOs, and 2 points for 80-meter CW QSOs. Pennsylvania stations multiply QSO points by the total number of ARRL sections plus the total number of Pennsylvania counties plus a maximum of one DX country. Others, multiply QSO points by the total number of Pennsylvania counties worked (67 max.).

AWARDS:

This year, in addition to the usual certificates, plaques will go to top scorers in both Eastern and Western Pennsylvania, top out-of-state station, top mobile station (assuming at least 3 entries), and top multi-operator entry.

ENTRIES:

Logs must be complete, be legible, and include a summary sheet. Also include a dup sheet for entries with over 100 QSOs. Send logs no later than November 15th to: Douglas R. Maddox W3HDH, 1187 S. Garner Street, State College PA 16801.

ARCI QRP CW QSO PARTY

Starts: 1200 GMT October 16
Ends: 2400 GMT October 17

The contest is open to all amateurs and all are eligible for the awards. Stations may be worked once per band for QSO and multiplier credits. Participants may operate a maximum of 24 hours during the contest period.

EXCHANGE:

Members—RST, state-province-country, and QRP number. Nonmembers—RST, state-province-country, and power output. Novices and Technicians add /N or /T after the QRP number or power.

SCORING:

Power: A 200 Watts or less; B > 200 Watts.
Underlined callsign means awarded certificate.
†Next MDC QSO Party 1800Z Oct. 23 to 2100Z Oct. 24, 1982

Each member QSO counts 5 points regardless of location. Nonmember QSOs are 2 points with US and Canadian stations, others are 4 points each. Nonmember Novice and Technician contacts count 3 points. Multipliers are as follows: 4-5 Watts, × 2; 3-4 Watts, × 4; 2-3 Watts, × 6; 1-2 Watts, × 8; less than 1 Watt, × 10. Entries from stations running more than 5 Watts output will count as check logs only. Stations are eligible for the following bonus multipliers: if 100% natural power (solar, wind, etc.) with no storage, × 2; if 100% battery power, × 5.

Final score is total QSO points times total number of states/provinces/countries per band times the power multiplier times the bonus multiplier (if any).

Note: VHF/UHF contacts must be direct—no repeater contacts are allowed.

FREQUENCIES:

1810, 3560, 7040, 14060, 21060, 28060, 50360.

Novice/Tech—3710, 7110, 21110, 28110.

All frequencies plus/minus to clear QRM.

AWARDS:

Certificates to the highest-scoring station in each state, province, or country with 2 or more entries. One certificate to highest-scoring Novice/Technician overall. Entries automatically considered for annual Triple Crowns of QRP Award.

LOGS AND ENTRIES:

Separate log sheets are suggested for each band for ease of scoring. Send full log data including full name, address, and bands used, plus work sheet showing details and time(s) off air. No log copies will be returned. Please indicate if you are a Novice or Technician. All entries desiring results and scores please enclose a business-size envelope with return postage for one ounce or an IRC. It is a condition of entry that the decision of the ARCI QRP Contest Chairman is final in case of dispute. Logs must be received by November 20th to qualify. Send all logs and data to: ARCI QRP Contest Chairman, William W. Dickerson WA2JOC, 352 Crampton Drive, Monroe MI 48161.

MARYLAND-DISTRICT OF COLUMBIA QSO PARTY

Starts: 1800 GMT October 23
Ends: 2100 GMT October 24

Sponsored by the Columbia Amateur Radio Association, the contest is open to all single-operator stations. The same station may be worked on each band and mode.

EXCHANGE:

QSO number; RS(T); and state, province, country, or MD county. Remember that Baltimore and Washington are independent cities!

SCORING:

MDC stations multiply total QSOs by the sum of Maryland counties, states, provinces, and countries. Others multiply MDC QSO total by number of Maryland counties and independent cities (25 max.). Also, multiply score by 1.5 if running 200 Watts or less.

FREQUENCIES:

Phone—3950, 7250, 14290, 21390, 28590.
CW—60 kHz up from low end.
Novice—3720, 7120, 21120, 28120.

AWARDS AND ENTRIES:

Maintain a continuous log for phone and CW but indicate on entry which category—phone, CW, or mixed—you are entering. Certificates for top scorers in each category will be awarded. Mail logs, dup sheets (for over 200 contacts), and summary by November 30th to CARA, c/o Robert K. Nauman WA3VUQ, 4017 Font Hill Drive, Ellicott City MD 21043.

SIDE WINDERS ON TWO (SWOT) OPEN QSO PARTY

Part 1
Starts: 0000 GMT October 2
Ends: 0600 GMT October 4

Part 2
Starts: 0000 GMT October 9
Ends: 0600 GMT October 11

This is the fifth annual QSO party sponsored by the SWOT Amateur Radio Club and open to all licensed amateurs with operating privileges on two meters. All entries must be single operator and contacts must be direct—no repeaters or satellites. Contacts must be on SSB or CW and each station can be counted only once. All contacts must be made from one geographic location. Portables or mobile stations operating from more than one county may submit the highest score for any one location. There are no time limitations within the contest period.

EXCHANGE:

Callsigns, signal reports, ARRL section, SWOT number, and USA county or equivalent.

SCORING:

Contacts with SWOT members count 2 points per QSO, others count 1 point each. The multiplier is the number of counties worked. Final score is QSO points times county multiplier.

ENTRIES:

Logs should not be submitted unless requested. Send only a summary postmarked no later than November 1st to: Jerome Doerrie K5IS, Rt. 2 Box 72, Booker TX 79005. The summary should contain: your name, call, address, ARRL section, SWOT number, total SWOT QSOs, total nonmember QSOs, total counties, and final score.

AWARDS

TREASURE ISLAND DXPEDITION

The Garden State ARA (W2GSA) will hold its 3rd annual special event: the Treasure Island DXpedition, located in the Manasquan River, Monmouth County NJ. The event is to commemorate the stay of Robert Louis Stevenson on the island after he wrote the book of the same name.

Date: October 2-3, 1982; time: 1400 to 1400; frequencies: CW—3.535, 14.035; SSB—3.900-7.235, 21.375-28.725. QSL certificate: $1.00 to Lou Eloe WA2SSH, 7 Carol Ave., Neptune NJ 07753. No postage necessary.

NUCLEAR ANNIVERSARY

The Argonne Amateur Radio Club plans to operate the Club's memorial station, W9QVE, to commemorate the 40th anniversary of the first controlled nulcear chain reaction experiment. This experiment was conducted at the Alonzo Stagg field on the University of Chicago campus.

Two stations will operate from 1500 GMT on October 9, 1982, through 2300 GMT, October 10th.

Frequencies: SSB—3985, 7285, 14285, 21285, 28585; CW—3545, 7045, 14045, 21045, 28045, 3765, 7165, 21165 Novice bands; RTTY—14090 and 146.70 MHz; 2 meter—145.19/144.59 rptr, 146.52 and 147.42 simplex.

Send business-size SASE or $1.00 for 8 × 11 unfolded certificate to AARC, PO Box 275, Argonne IL 60439.

SUNBELT EXPO

The Colquitt County Ham Radio Society will be operating club station WD4KOW from the site of the fifth annual Sunbelt Agricultural Exposition on October 12, 13, and 14, 1982. The hours of operation will be 0900 to 1700 EDST each day.

This annual Expo is held each year at Spence Field Airbase, located near Moultrie, Georgia, and is the largest agricultural show in the South. This event draws over 200,000 visitors from all over the United States and foreign countries.

Operations will be in the General portion of the HF bands. The members will also be listening for visiting hams on the local repeater, 146.19/.79. Visiting hams are invited to visit the amateur booth at the Expo and operate the amateur station.

A special QSL card is available for those making contact during this event and submitting an SASE. For more information, contact Joel Goings AA4P, PO Box 813, Moultrie GA 31768, or call (912)-985-3620.

NEWNAN GA

The Bill Gremillion Memorial Radio Club will operate K4SEX for county hunters on Saturday, October 2. Frequencies: General-class portion of phone bands on 10, 15, 20, 40, and 80 meters. CW available. Send an SASE for confirmation to: Bill Gremillion Memorial Radio Club, PO Box 2327, Newnan GA 30264.

MOSCOW DXPEDITION

Moscow MI: The Hillsdale County Radio Association will hold its 2nd Annual Moscow DXpedition to Moscow, Michigan on October 16 from 1700Z to 1700Z October 17, under the call WB8HIZ. The frequencies to be used: 3.940, 7.280, 14.285, 21.360, 50.120, 52.525, 144.310, 146.57 MHz, or as band conditions permit. The exchange will be signal report, name, QTH (except Moscow station: serial number). All QSLs with an SASE will be answered with a 9"x11" certificate. Mail to: Ham, PO Box 206, Moscow MI 49257.

HERITAGE HOLIDAYS

The Coosa Valley Amateur Radio Club will operate from Rome GA from 1200Z October 9 to 2200Z October 17 to commemorate Heritage Holidays. 25 kHz on the lower side of the General-class phone band—80 through 20 meters. Special certificate for a large SASE. Wagon Train mobile on Oct. 16. Endorsement to CVARC, Box 183, Rome GA 30161.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every place of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I need the following equipment: URM-124, TS1325/TRC-75, TS1324/TRC-75 (also need test sets for this), GRM-21, CU-749/TRC-75, and C2848/TRC-75 (also need antenna coupler for this).

I also need the following modules (these are for the R761/ARC-58): AM 1528B/URC, CV465C/URC, SG-179A/URC, and SG-179B/URC.

I also need the following: AT-197/GR (antenna), TT98/FG (Teletype™), MK-731/ARC-51X (maintenance kit), ARC-134 (radio), ARC-54, 618T, PRC-74B, APA-69 (DF group), RT 524/VRC or RT 246/VRC, OA-3633/GRC, PRC-47, R1149/ARC-58(V), C1939/ARC-58, R1051/URR, URC-9, R220/URR or R640/URR, ARM-48 test set, ARM-47 test set, and ARM-11C.

I will pay reasonable costs for any o the above. Thank you.

Leroy Ritt

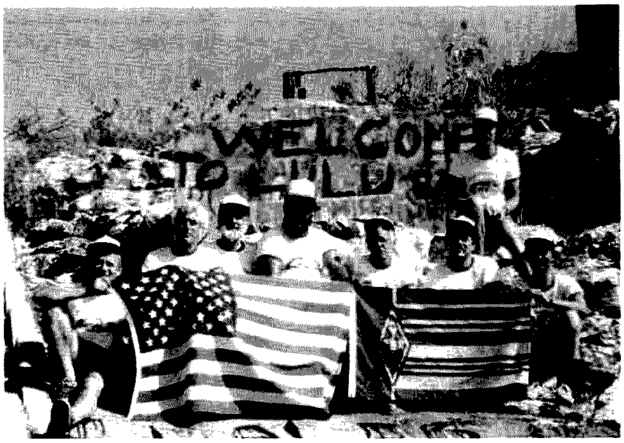
NAVASSA ISLAND KP2A/KP1

An automated lighthouse caps the tiny island of Navassa, a few miles off the coast of Haiti. Navassa meets the sea in an unbroken ring of high cliffs, with no safe harbor or landing site. It lies 15 hours from the nearest assistance by boat and even further from help by any other means. But Navassa's status as a separate "country" under ARRL DXCC rules ensures a continuing flow of DXers to the island.

The latest and most successful such DXpedition invaded Navassa this last March, under the auspices of the International DX Foundation. One member of that trip, Terry Baxter N6CW, related his experiences to me at the International DX Convention in Visalia CA last April. Thanks to Terry for this story.

John Ackley KP2A had often thought of a DXpedition to nearby Navassa. The island is perfect for such a trip: It is within a reasonable boat ride from well-stocked ports; licensing is automatic, as it is part of the United States; the Coast Guard is reasonable about issuing landing permission; and it is a known quantity. In other words, you know exactly what you are getting into, unlike some more disputed DX locations, such as Spratiy. The fact that Navassa did not rank in the top 73 of the most wanted list from *The DX Bulletin* survey (the benchmark of all such listings) was the only drawback to the operation. But increasing interest in DX throughout the world ensured plenty of interest in such a trip. John pressed ahead.

W2IJB climbs the infamous Navassa Ladder while K8CW provided moral support. Imagine hauling all the DXpedition material up this ladder, from a tiny dinghy tossing in the waves!



The KP2A/KP1 crew at Lulu Bay on Navassa. From left: WA2MOE, KP2A, WØDX/VP2VI, KØOO, W2IJB, N2OO, K1MEM; N6CW in back.

He had plenty of help. He had founded the International DX Foundation in 1978 to promote international goodwill through just such DXpeditions. The IDXF would provide major funding for the trip, especially for the equipment. But the trip would still cost almost $10,000. Where would the rest of the money come from? The answer was the same that many other DXpeditions have used: Get more operators and divide the costs among them.

Finding amateurs with the funds, the free time, and the inclination to travel to Navassa was not easy. An early recruit was Bob Denniston WØDX/VP2VI, from the neighboring British Virgin Islands. Bob's illustrious amateur career has included the presidency of the ARRL and the IARU. He also organized the first DXpedition to Clipperton Island in 1954 and is one of the few amateurs ever to return there. He claims two trips to Malpelo as well, including the first radio operation from that rock. Bob presently runs a small hotel on Tortola In the BVI and is active in CW contests and on 160 meters. An amateur of Bob's experience was a great plus in a major DXpedition.

The cast of characters continued to assemble. Hams with DXpedition experience and operating expertise were lined up. A former president of the San Diego DX Club, Terry Baxter N6CW, was a frequent visitor to the British Virgin Islands, especially during the *CQ* WW CW contests, when he would operate as VP2VDH. Terry's eyeball contacts with Bob Denniston eventually led to a spot on the trip.

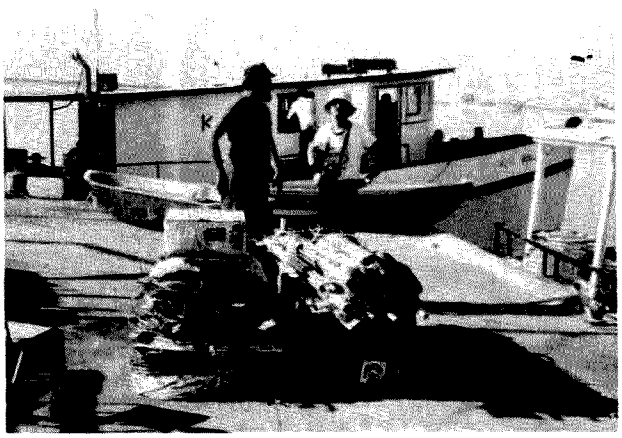
Another member of the team was Ed Magnuson W2IJB. Ed is a Senior Editor of *Time* magazine, and his presence led to a feature article on the DXpedition in the May 3, 1982, issue of *Time*. The other operators were K8CW, N2OO, KØOO, K1MEM, and WA2MOE. The time for the trip was approaching.

During the second week of March, the DXpeditioners made their own way to Kingston, Jamaica, the nearest staging point for the DXpedition. Although Navassa lies far closer to Haiti than to Jamaica, it is much closer to the port of Kingston than to the nearest port in Haiti, Port-au-Prince. And accommodations and supplies are far better in Jamaica.

By Sunday, March 14, all nine members of the operating team were in Jamaica. Dr. John Manley 6Y5MJ provided local support, scouting out a suitable boat and places to stay, and helping with the herculean task of assembling the necessary equipment to send nine operators and six crew members to Navassa. Food, water, gasoline, diesel fuel, barrels, steel pipe for masts, ropes, tents, and more were assembled. One has to anticipate every possible need and stock accordingly. And this list doesn't even include the radio equipment and antennas. When the nearest Radio Shack is days away, the lack of a single coaxial connector can be devastating.

By 6:00 pm on Monday, all the supplies were safely stowed on board the 48' fishing boat

W2IJB and K1MEM in front of one of the operating positions. Note the hill in the background blocking the path to Europe.



KØOO and K1MEM examine a small fraction of the DXpedition equipment and supplies in Kingston, Jamaica, before boarding the boat Gabriella *for Navassa.*

Gabriella and the DXpedition shoved off. For the next 15 hours, the sturdy boat battled the current and trade winds, fighting its way 150 miles east and north toward the low silhouette of Navassa. And all night the amateurs discovered that proficiency at ham radio is no protection from the ills of seasickness. While it may be true that nobody has ever died of *mal de mer*, everyone so stricken certainly wishes he could. An inauspicious beginning to the trip; what would the next day bring?

At dawn, the *Gabriella* was anchored firmly off the Navassa landing site at Lulu Bay. There are exactly two ways to get from the anchorage to the island: the Coast Guard way, via helicopter, or the radio amateur way, via The Ladder. The Coast Guard description of access to the island includes this warning: "There is constant danger of the boat being broached by the incoming swell, being smashed against the cliff, being caught and crusted under the cliff, or being engulfed by the receding backwash." Instead of a landing, a steel and wire ladder hangs 40 feet down to near the water line. "Landing" at Navassa means maneuvering your dinghy under the steel ladder (presumably avoiding the aforementioned dangers) and, catching the 5'-10' swells just right, leaping out of the dinghy to the ladder. Then, an easy climb up two-foot rungs of angle iron to the tiny platform and you're ashore on Navassa.

Multiply this task by nine to get the operators ashore, and then think about moving the tons of equipment and supplies from the boat to the dinghy, under the ladder, and up to the island. Two generators, barrels of gasoline, four complete stations, 3 tribanders, an amplifier, food, water, and tents—all the hardware for a week-long DXpedition had to be shuttled in to the ladder and hauled up to the platform. But even that was not the end of the task. The platform is 50 feet below the nearest flat spot on the island. A set of rough stone steps leads up from the platform to the first, lower plateau. K8CW devised an ingenious cart which rolled up the ramp by the steps, until it failed under the heavy loads. Elbow grease and armstrong power prevailed, and the gear slowly began to accumulate on the lower plateau.

But suddenly *Gabriella*'s warning horn blasted. The hams on the island switched on their HTs to hear the chilling news that a couple of small, open boats had suddenly appeared and two men were climbing the ladder. Were the intruders some of the notorious pirates which frequent these waters? Haitians bent on revenge against the American oppressors? Stu Greene WA2MOE's fractured French soon allayed both fears. The Haitian fishermen had rowed across 40 miles of open water in tiny rowboats looking for better fishing grounds. They would be pleased to help unload the dinghy and haul the hundreds of pounds of remaining equipment up to the operating site in exchange for some food. The deal was quickly struck and the amateurs resumed the task of assembling the actual stations. Even with the help of the fishermen, it took two days to transport all the gear from the *Gabriella* to Navassa.

Meanwhile, KP2A/KP1 struggled to get on the air. Having abandoned the original plan of transporting all the gear to the island first, John and the other amateurs concentrated on the generators and antennas. After all, the food and water could come over any time, but the whole world was waiting for the first QSO. And Tuesday night, KP2A/KP1 did indeed hit the airways, with the first of more than 33,500 QSOs.

The hams set up separate stations along the ledge. The higher frequency bands boasted TH3s on 20' steel poles. Dipoles sufficed for the lower bands, with the 40-meter dipole doubling as a 15-meter antenna during the day. Six meters was a big disappointment, with only 15 QSOs (all South Americans). But 160 meters made up for any lack of propagation on 6. Bob Dennisston strung a dipole across an inlet of the ocean, nearly 100' above the water. He then made 87 separate trips back and forth between the rig and the antenna to properly tune the dipole. His perseverance paid off: KP2A/KP1 logged 522 QSOs on 160!

The other operators manned all the other stations, and averaged more than 4 QSOs per minute of operation! The hill to the northeast blocked European signals somewhat, but CW provided thousands of European contacts. In fact, the 33,000+ QSOs were evenly divided between SSB and CW, with many of the CW QSOs coming from outside the States. Eight percent of the stateside QSOs were on SSB. The six CW operators on Navassa were a fussy lot: Each brought his own keyer and paddle! The keyers and paddles crowded the tiny tables, but a major DXpedition is no time to learn someone else's keyer! The DXpedition avoided lists completely and even managed to work most contacts on frequency, only resorting to split-frequency operation a few times. Band conditions permitted barefoot operation on all but 20 meters in the evening, which helped reduce gasoline consumption to one barrel from the anticipated three.

During infrequent breaks in operating, the hams explored what little of Navassa is worth examining. Graffiti reading turned out to be the biggest thrill of the trip, as Coast Guard regulations prohibit alcoholic beverages on Navassa.

The time came to leave Navassa and the DXpedition crew began the long task of disassembling the gear and shuttling the equipment back to the *Gabriella*. With no major emergencies and more than 33,500 QSOs in the logs, the KP2A/KP1 DXpedition must rank as one of the most successful ever. And months later, the first of tens of thousands of QSL cards hit the mails (QSL via WB2MSH). Thousands of amateurs are indebted to the Navassa operators for "a new one." Let's hope the Heard Island trip meets with equal success.

(I would like to thank *Time* magazine, the International DX Foundation, *The DX Bulletin*, and especially Terry Baxter N6CW for the information in this month's column.)

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR,
4006 Winlee Road
Randallstown MD 21133

Well, with this time of year comes the announcement of what has become an autumn tradition, the SCATS RTTY Art Contest. Mae Washburn WA6LNH, of the Southern Counties (California) Amateur Teleprinter Society, sends along the official announcement of this year's competition, which includes several changes from previous years.

The contest period is from September 1, 1982, to November 30, 1982, and is open to licensed amateurs worldwide. Entries must have been originated by means of *manual* input to a teleprinter using a standard communications keyboard. Sorry, folks, no computer-generated pictures! Either the amateur or an amateur's family member may be the originator. The subject matter must be "suitable for transmission via amateur radio."

Tapes of entries should be five-level, 11/16th-inch-width, run no longer than 40 minutes at 60-wpm speed, and be unspliced. They should be compatible with machines which both do and do not downshift on space. For those of you who are confused by that, it means that if you are sending in uppercase (FIGS) and have to send one or more spaces, follow the space with another FIGS character. Conversely, if you are changing from upper- to lowercase, do not depend on the space to effect the change—send a LETTERS character. Got it?

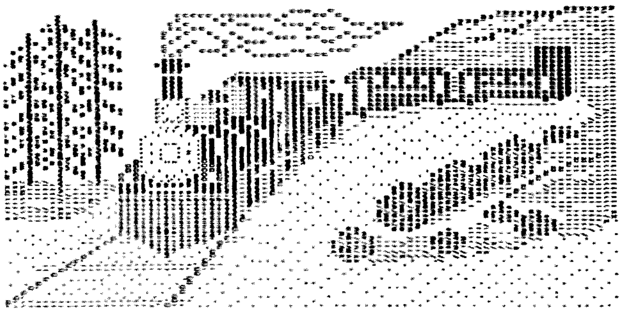
More particulars: No need to worry about BELL and apostrophe problems—they will allow for that. Between you and me, though, I normally send one of each (that is FIGS-J and FIGS-S) to be sure that the apostrophe is printed. A line should terminate with a CAR-RET/LINE FEED/LETTERS sequence, at a minimum. I normally throw in an extra carriage return, though!

Now, an important difference from previous years is the limitation of each line to *68* characters, rather than 72. This is to accommodate some of the European equipment which was unable to display the longer line length.

The artwork must have been transmitted for the first time via amateur radio after September 1, 1982, and have written confirmation received. There are some more particulars, available in the full list of rules available from SCATS. Write to the RTTY Art Contest, c/o Norm Koch K6ZDL, PO Box 1351, Torrance CA 90505.

The winners of the 1981 contest, whose works are reprinted here, include Jean Carter KA6HJK of Buena Park CA, for her entry, "The Railroad." This is Jean's first year as a ham, her first entry in a RTTY Art contest, and she won the first prize! Second place went to Alfred La Vorgna WA2OQJ of Hicksville NY, for "A Prize In Every Box," and third place went to Charles Pike K3YUH of Monica PA, for his comical "What's Up, Doc?" Honorable mention saw a tie between Bent Pederson OZ5RT, of Copenhagen, Denmark, who submitted "The Wild Horse," and Richard Camp WA7NGN of Las Vegas NV, with "Freddy Fender." Why not try your hand this year, and see if your work can grace the pages of *73* next year?

Several club newsletters cross my desk each month, and I would like to take a moment to acknowledge some of them. The Inland Empire RTTY Network, out in San Bernardino CA, puts out a nice mimeographed newsletter which describes their repeater and club functions. A nice map describing coverage areas and linkages of two-meter RTTY repeaters is a welcome addition to the paper. The Stark RTTY Group, in Massillon OH, has thoroughly revised its publication, *Watts Happening*. No longer a few hectographed sheets, it is now an impressive little booklet complete with features and ads. Terry Russ N8ATZ, the editor of the newsletter, has done a fine job and I'm sure the membership will benefit.



First place: Jean Carter KA6HJK.

Second place: Alfred La Vorgna WA2OQJ.

Also in the mail are letters. Oh, boy, are there letters! I am going to try to cut down this backlog over the next few months and put the questions of widest interest here in the column for all to see. This month, Kurt A. Theis WA6YDQ, from Citrus Heights CA, gets the spotlight. Kurt asks several questions which just delight the heart of a columnist like yours truly. I shall respond in order.

Kurt asks, "On the Model 15, under the carriage there are several bars running through a metal plate. On the plate are stamped certain characters, among them "TAB", "STOP", and "LF". Do the TAB and STOP have any use in ham RTTY and, if so, how do I make use of them?" Well, Kurt, the hunk of metal you are looking at is the blocking bail on a function lever. Several of the machine functions you note, most importantly TABulation, are available in specially-equipped machines. However, I know of no ham use for these functions, as they are not supported in the vast number of machines. And since the Teletype® Model 15 is no longer being manufactured, I guess not too many more will be coming out of the showroom so fully equipped.

Next, Kurt inquires, "I have read a couple of books on RTTY and come across a few things that I would like to try if possible. One of them is SELCAL. I would like to set this up in the shack but I don't know if it would be useful. Is SELCAL used very often in RTTY? Would it be better to use a microprocessor in the decoding or to just build a hardware device for it?" Been reading this column, Kurt? No, seriously, SELCAL, or SELective CALling, is a takeoff on a concept that has been bumping around RTTY for forty years. Originally mechanical, with wheels and disks, this was one of the first fronts to give way to digital electronics. These days, selective calling of one form or

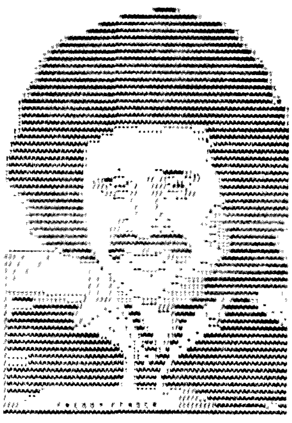
Third place: Charles L. Pike K3YUH.

another is still quite in use, but with far more sophisticated techniques than in years past. For flexibility and ease of use, I don't think there is another way to go. If you want to implement this mode in 1982, then try a microprocessor. You might peruse back issues of *73*. Better yet, ask around the air to get a sense of the diversity of equipment in use.

We can deal with Kurt's third question easily. "Are regenerative repeaters used a lot any more, and are the surplus units lying around any good?" With few exceptions, no.

"Is the BLANK key ever used?" For what, Kurt? Some folks like to idle on the blank, others on the letters. Many tape systems are set up to shut down or disable the keyboard upon receipt of a blank, so it's best not to use it. You would not want to gag the guy you are in QSO with, would you?

Finally, "I have been listening in on some electronic mailboxes and others sending traffic and other personal messages via autostart. If the receiving operator is not there to answer back right away, wouldn't that be a one-way communication that the FCC keeps saying we can't use?" The problem here is not only one-way transmission, although that can be gotten around just as so-called "bulletin stations" have been doing for years, but the non-attended RTTY station. If the receiving station does just that, receive, I don't think you can get too upset. However, if the receiving station automatically takes to the air, unattended, to acknowledge receipt of a message without an operator being present, you are certainly skirting the law. Now, I know that even years ago there were WRU (Who Are You) and Answer Back circuits which did much the same thing, but they weren't any more legal back then. For me, I would feel much more comfortable not enabling a transmitter to answer unless there is a human control operator around to shut things down if something happens.



Honorable mention: Richard Camp WA7VGN.

Honorable mention: Bent Pedersen OZ5RT.

As I write this column, I have been looking around at various eight-inch disk systems (DS-DD) for my computer, a Smoke/GIMIX/6800 system. I am appalled at the dearth of information published or available on the various manufacturers' products. Not only that, but each manufacturer states that his drive is best, and adds how this one tears up media, or fails prematurely, or requires recall modifications to keep going. I don't know how anyone can make an informed choice.

Computer RTTY is leading the mechanical type in the mail by a wide margin, so I shall try to keep the main line where the action is. If you have a topic you wish to see covered in this column, feel free to drop me a line at the above address. I usually answer mail that has a self-addressed stamped envelope—not promptly, but I get there. Other mail is answered in this column only, and then only if it is of general interest. Watch closely: Some reviews of recently released commercial equipment may even find their way in here now and then.

ATTENTION: ICOM & KENWOOD OWNERS!!

IF YOU ARE NOT RECEIVING OUR MONTHLY NEWSLETTERS, YOU ARE NOT TUNED INTO A WEALTH OF INFORMATION!!!

SATELLITES

SATELLITE QSL BUREAU

One vastly under-utilized resource available to all amateur satellite users is the AMSAT-OSCAR QSL bureau. It works like most such bureaus: Operators keep self-addressed, stamped envelopes on file at the bureau and incoming cards are sorted and periodically mailed out in the envelopes. The only problem, according to bureau manager Bill Luebkemann WB2LCC, is that many satellite buffs aren't currently using the bureau, resulting in a large backlog of unclaimed cards. At midsummer, for instance, the bureau was holding some 1500 unclaimed cards for more than 700 different stations.

To receive cards from the bureau, send Bill up to six self-addressed, stamped #10 envelopes. Foreign stations may send IRCs instead of postage. Your callsign only goes in the upper left-hand corner where the return address would normally appear. Once a month, any cards on file for your station will be mailed using one or more of your envelopes.

Cards to be sent through the bureau should have the callsign of the intended recipient placed on the right rear of each card. The cards should then be put in alphabetical order before being shipped to the bureau. There is a five-cent charge for each card addressed to a station outside North America. All other services of the bureau are free.

For more details about the AMSAT-OSCAR QSL bureau, write to WB2LCC, 116 Country Farms Road, Marlton NJ 08053.

THE UoSAT SAGA

A 150-foot parabolic dish antenna was being used this summer in what appeared to be a last-ditch effort to save the ill-fated University of Surrey amateur satellite. The dish, which provides 42 dB gain at 435 MHz, will be used in an attempt to issue commands to the satellite.

The drastic action was made necessary when a software error caused both the 144- and 435-MHz beacons aboard UoSAT to be commanded on simultaneously. As a result, both command receivers are being desensed by the beacons. It is hoped that the very high erp of the big dish will be sufficient to overcome the desense problem and turn off one of the beacons. An earlier rescue attempt using the 26-dB 2-meter EME array of K1WHS proved unsuccessful despite Dave's considerable effort.

Thanks to the *AMSAT Satellite Report* for this information.—WB8BTH.

I need crystals for use in an antique "cat's-whisker"-type radio receiver.

B. Frank Vogel, MD WB5PMU
208 Chief St.
Cherokee IA 51012

Can anyone sell me a Mini-Products HQ-1 mini-quad or a B-24/RK-3 mini-beam? Please write first.

Ash Nallawalla VK3CIT
RAAF Academy
Point Cook, Vic. 3029
Australia

I need manuals and/or schematics for the following:

- •Sierra Electronics model 219B transistor tester
- •TS-323/UR frequency meter
- •OS-37/UPM-45 oscilloscope
- •Heath OP-1 oscilloscope
- •Heath O-12 oscilloscope
- •RCA WR-99A crystal-calibrated marker generator
- •Simpson 383-A capacohmeter
- •Konel KR53VA VHF transceiver

I will pay reasonable costs for copying and postage.

Chuck Gerttula
285 S. Cedar
Toledo OR 97391

I need a schematic for a model SE 9176 Sonex cassette recorder.

Harvey C. Brown WD6DRF
PO Box 32275
San Jose CA 95132

Can anyone help me get started in ham radio?

Mrs. Kathryn Wilson
2 Foundry St.
So. Easton MA 02375

CORRECTIONS

Several errors crept into our two-part "Confessions of a Counter Evolutionary" article. In part I (August, 1982), line 9 of column 3 should read: "connections) and R6//R7."

In part II (September, 1982), the following corrections should be made:

- •On Fig. 12 (page 39), pin 12 of IC26 must be connected to pin 9 of the IC before the common connection goes to pin 10 of IC35.
- •In column 2 on page 42 of the article, line 11 should be changed to read "strobes 1-7, not 2-8."
- •On page 42, column 4, paragraph 3, line 5 should read: "2x1¾-inch Bud 2100)."
- •On Fig. 17 (page 44), eliminate the dashed box around the three 74LS04 chips. (Keep in mind that all three ICs are still 74LS04s.)
- •On page 46, column 1, paragraph 1, line 5, the word "Yet" should be omitted.

Charles E. Martin AB4Y
***73 Magazine* Staff**

In the article "Double Trouble on 50 MHz" (September, 1982), the following corrections should be made:

- •Q6 and Q7 are 2N1566A NPN transistors.
- •The .001-microfarad capacitor should be a *fixed*, not variable, capacitor.

Charles E. Martin AB4Y
***73 Magazine* Staff**

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. 827-5732 (Beno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Diego CA

We buy and sell Surplus Army Navy Electronics, also Terminated Material. What do you want to sell? Write for catalogue. **Electronictown, Inc., 440-7th Avenue, PO Box 2048, San Diego CA 92112, 232-9379.**

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full Line of Accessories. No Sales Tax in Delaware. One mile off I-95. **Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Smyrna CA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. **Britt's Two-Way Radio, 2506 N. Atlanta Rd., Smyrna GA 30080, 432-8006.**

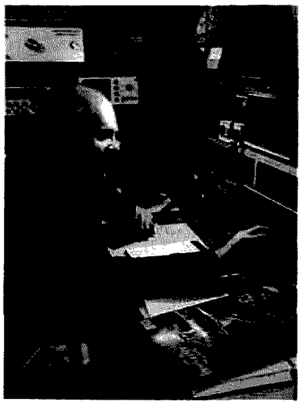
W2NSD/1
NEVER SAY DIE
editorial by Wayne Green



WHERE'S THE SOLDER?

For years, the pride of my workbench was my 300-Watt soldering iron. I looked for it the other day, thinking I might frame it as a historic remnant of a long lost past, and couldn't find it. Well, I don't need that old 300-Watter anymore anyway. These days, a simple pencil iron is enough to do irreparable damage. Some of these damned chips we use today would probably self-destruct if just allowed in the room with the 300-Watt iron. But the fact is that though the tools have changed, we're getting into an era of a high interest in building electronic gadgets.

The recent emphasis on relatively simple building projects in *73* has brought in quite a bit of congratulatory mail. It's appreciated. You know, when I started *73*, back in 1960, one of the basic reasons I felt that the magazine was needed was to encourage hams to build more. As the editor, I'd had one hell of a battle with the publisher of *CQ* over this. He wanted monthly columns, which were a lot cheaper to publish. I'd built the magazine up from a real loser to a big winner with construction...and found myself fired. So I started *73* and got right at it with construction projects.

Just to make sure that you know right off when you look at the table of contents on the cover, we'll put a soldering-iron logo by each project. Mind you, these are not going to be all-band transceivers which could take you a year to build. I'll still leave those for *Ham Radio*, if they stay afloat.

While it may go without saying that I'm hoping you will write up any construction projects you develop, let me make sure that there is no misunderstanding here. If you design something which might be of interest to the rest of *73* readers, I hope you'll write it up. Type the article double-spaced, leave generous margins, get a friend with a good camera to take art-gallery-class photos of your gem...and let's have it.

Sure, it's fun to operate. But I've never gotten so wrapped up in operating that I missed a meal. Now building...many is the time I've started working on a project and found myself looking at the rising sun, having missed dinner, midnight snack, and all those usual buffering pick-me-ups in between. Hell, building something is more fun than coffee ice cream.

And yes, you can go fairly far afield. Sure, we're mostly interested in amateur radio, but that won't stop us from publishing interesting projects which are involved with other aspects of life such as photography, computers, and so on. You'll get my attention the fastest with gadgets which tie computers and amateur radio together. I know as well as you that we have the tools to make incredible changes in communications over the next few years. It's getting time for us to grab those tools and carve out some pioneer territory with high-speed Morse, RTTY, or ASCII...or whatever pleases you.

We have the parts to make incredibly sophisticated repeaters...yet I've seen little to amaze me so far. Let's get cracking...and writing. I'll publish...and pay.

CIRCUITS CIRCUITS CIRCUITS

Some years ago I began reprinting little circuits out of foreign electronics magazines which I thought might interest the more dedicated experimenter. They were presented with very little backup information ...just enough for the experienced builder to put the project together and get it working. We're running that section again and would like to have you send in little circuits for almost anything. You don't have to put together a whole article—just the circuit, the parts values, and a hint of what it will do. Perhaps you've found a circuit from some other (non-ham) magazine which readers might find of value...or from a book. We'll scan the foreign magazines and see what we can find for you. You don't have to draft the circuits. Just sketch them clearly, showing all parts values. If there are any special parts, show what they are and where they can be obtained. The address is Circuits, Editorial Offices, *73 Magazine*, Peterborough NH 03458. By the way, don't forget to include your choice of book from the Radio Bookshop, which we'll send you when your circuit is published.

For that matter, authors of articles on construction projects should remember that *73* is read in over 200 countries and that in most of them parts are darned hard to come by. Thus, if there is any way to do it, try to use commonly available parts...or at least suggest such as replacements if you've used a 1963 transistor in your unit. A builder in Chile will not be happy if you merely specify a Radio Shack part number...give a bit more in details since his Radio Shack may not carry the full line.

One of the main reasons why *73* is so treasured by DX hams is that it runs more construction projects than any other ham magazine in English in the world. We can't come close to the Japanese ham magazine, but then they have about three times as many active hams there as we do, so that's natural. If I could get someone to translate the Japanese construction projects, I could put out a couple

TECHNICAL EDITOR WANTED

The search is on! We're looking for a knowledgeable ham to become Technical Editor of *73 Magazine*. If you enjoy our small-construction-project format and can tell a good circuit from a bummer, then you're a prime candidate.

Duties of the Tech Editor include checking the technical accuracy of articles, working with authors to get the best new manuscripts, making sure *73* publishes timely reviews of the latest ham gear, climbing the tower to repair the 20-meter beam, installing Wayne's new mobile rigs, etc. There is plenty of opportunity for fun, too, working contests from W2NSD, learning about microcomputers, mountaintopping from the drive-up peak just down the road.

Furthermore, Peterborough just happens to be located in one of the most beautiful areas of the country. The quality of life is superb. Sound interesting? If you are a non-smoker, we'd like to hear from you. Resumes should be sent to Jeff DeTray, Wayne Green, Inc., Peterborough NH 03458.

hundred pages a month of things for you to build.

I've mentioned before that if you have a DX friend you can help him a lot by giving him a subscription to *73*. The magazine gets positively worn out in most countries. A few years ago, when the dollar was weak, they had no problem getting the magazine, but today it's almost prohibitive in many countries. Of course, behind the Iron Curtain they are not permitted to send money for magazine subscriptions, so they have to depend entirely on the friendship of fellow hams who are more fortunate in where they live.

CQ FAILS CODE TEST!

One of our readers in New Mexico sent in an envelope he received from our friends at *CQ*. On the cover is a bunch of Morse code. The reader translated the code for us, chuckling

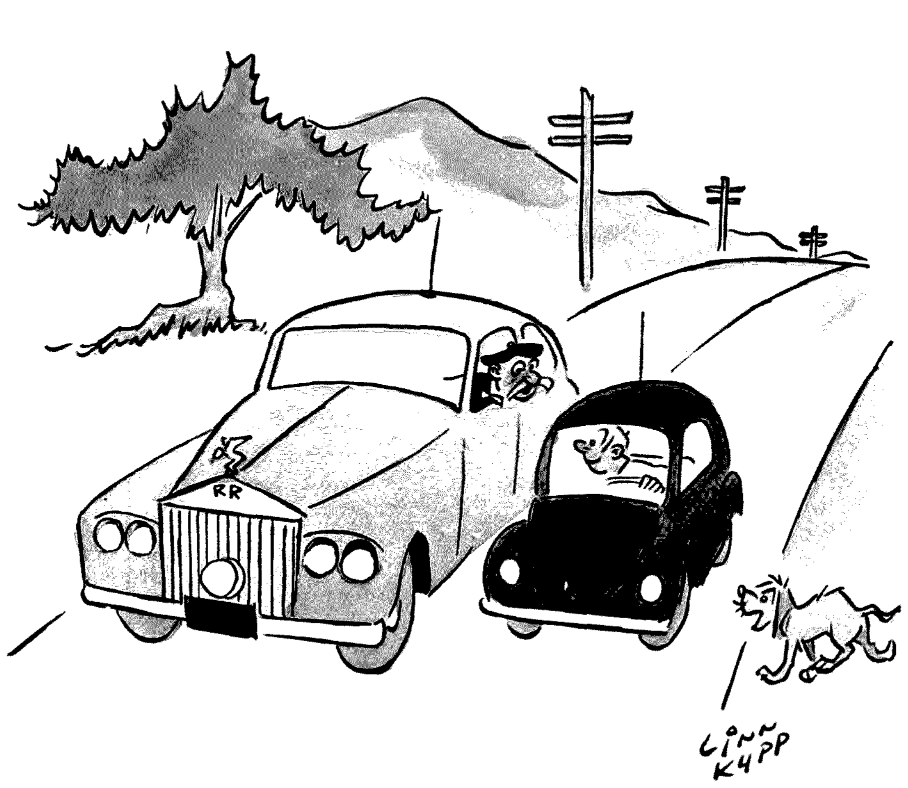
Continued on page 140

QSL OF THE MONTH: AG5X

This month's winning QSL is from Bob Jackson AG5X of Webster TX. Bob has a stunningly simple ultra-modern QSL design. The callsign is presented visually around the upper left-hand perimeter of the card. The callsign is displayed in modern type in the lower right-hand space balancing the image and contributing to the overall pleasing effect of the card.

To enter *73 Magazine*'s QSL of the Month Contest send your QSL in an envelope to: Editorial Offices, *73 Magazine*, Peterborough NH 03458. Specify a book from *73*'s Radio Bookshop (located elsewhere in this magazine). Entries which are not in an envelope or do not select a book will not be considered.

Well . . . I Can Dream, Can't I? by Bandel Linn K4PP



"I'm the guy you were talking to on 2 meters! Please follow me to our yacht landing for dinner!"

Mike Strange WA2BHB
PO Box 58
Pine Hill NJ 08021

A Perfect "10"

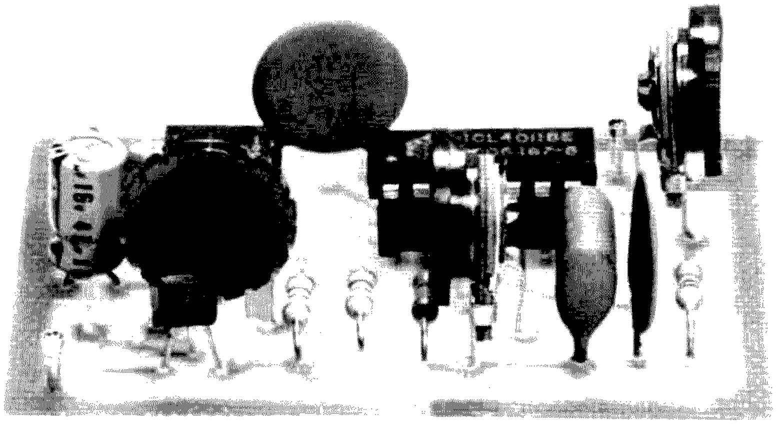
Timer, counter, logic probe—10 functions in all. That's the Multi-Board One, and you can build it.

Ed. Note: WA2BHB's article was one of the honorable mention winners in our Home-Brew Contest. Mike will be receiving a $50 bonus in addition to his normal article payment.

The Multi-Board One (MB-1) started out as a circuit to give a courtesy beep indicating time-out reset on my repeater. A quick prototype showed that with a few extra components, the circuit could be a handy gadget to have in the shack, too. Being a home-brew nut, I'm always needing an extra gated signal source, another trigger, an oscillator, or just one more logic level indicator, etc. I always seem to be one short of whatever it is I need to prototype a new design. Well, the MB-1 was the answer to my problems. It satisfied the two basic requirements to be an addition to my bench: It was cheap, and it did more than one thing (10 in fact!).

The MB-1 as designed is all on one 1¾" × 2½" printed circuit board and can perform the following functions:

- Variable signal generator up to 500 kHz
- Adjustable positive gated astable oscillator
- Adjustable negative gated astable oscillator
- Adjustable positive gated monostable
- Adjustable negative gated monostable
- Adjustable timer with normally off output
- Adjustable timer with normally on output
- TTL/CMOS logic probe, with audible and LED output indicators
- Pulse stretcher
- Repeater beeper



An assembled MB-1. A complete kit of all parts and a G10 reflow soldered printed circuit board is available for $12 postpaid from W-S Engineering Corp., PO Box 58, Pine Hill NJ 08021; telephone (201)-852-0269.

Fig. 1 shows the schematic. It is simple and easy to build. The photo shows a completed unit. Fig. 2 shows the connection/jumper assignments needed to create any of the various MB-1 functions. See Fig. 3 for component layout with jumper hole assignments labeled with letters.

All adjustments for oscillator frequency, pulse length, and output level are on the printed circuit board. You may want to replace the board-mounted trimpots

with multiturn panel-mounted units and the timing capacitor can be mounted with additional capacitors on a rotary wafer switch so you can have several ranges available. The variations are endless and, for a few dollars, you can create a lot of useful test gear for the shack.

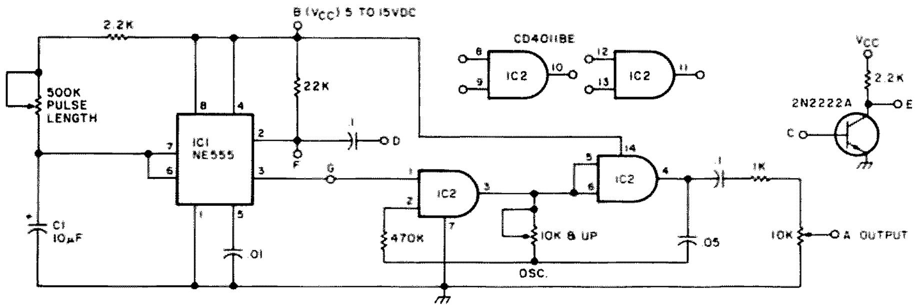


Fig. 1. MB-1 schematic.

Theory of Operation

The Multi-Board One uses a basic RC oscillator with an enable signal being provided by a 555 timer setup in various trigger modes. One half of a 4011 quad NAND gate is set up with a positive enable input at pin 1 driven by the output of the 555 timer. The output of pin 3 of the 555 timer is normally low, so the 4011 oscillator is off. When pin 3 goes high, the oscillator turns on. Pin 2 of the 555 is the trigger input. When a negative-going pulse causes the voltage at this point to drop to below one-third of Vcc, the output of the 555 (pin 3) goes high and the 4011 oscillator turns on. If pin 2 of the 555 is held low (grounded), the oscillator acts as a generator.

The *pulse length* potentiometer controls the duration of the high output of the 555 (pin 3, point F). Anything 10k Ohms or greater can be used. The larger the value of this potentiometer and the larger the value of C1, the longer the "on" dura-

Function	Input	Output	Interconnections
1. Signal Generator	1. None	1. Point A Ac signal, will drive 8-Ohms & up	1. Point F jumpered to ground
2. Beeper and Positive Gated Astable	2. Point C through 22k resistor	2. Point A Pulse of ac	2. Jumper point E to F
3. Beeper and Negative Gated Astable	3. Point D with a negative-going pulse	3. Point A Pulse of ac	3. None
4. Positive Trigger Monostable	4. Same as #2	4. Point G Dc pulse	4. Same as #2
5. Negative Trigger Monostable	5. Same as #3	5. Same as #4	5. None
6. Audible CMOS Logic Probe (See Note #1)	6. Tie points 8 & 9 together. Put a 100k resistor from 8 & 9 to ground. Points 8 & 9 are now the Input.	6. Point A Ac signal to speaker	6. Point 10 to F Connect point B to power source of CMOS circuit being checked.
7. CMOS Logic Probe with LED output	7. Same as #6	7. Same as #6 for audio. For LED, positive LED leg to point G, other leg through 1k to ground	7. Same as #6
8. CMOS Logic Probe with Pulse Stretcher (See Note #2)	8. Same as #6	8. Same as #6 or #7 as desired	8. Same as #6
9. Reverse Logic for #6,7,8	9. Same as #6	9. Same as #6 or #7	9. Point 10 to points 12 & 13. Point 11 to F.

Note #1: Set duration potentiometer to minimum so there is no delay.
Note #2: Set duration potentiometer to position of desired "pulse stretch" length.
All instructions assume ground and power connections are correct.

Fig. 2. Hookup connection function chart.

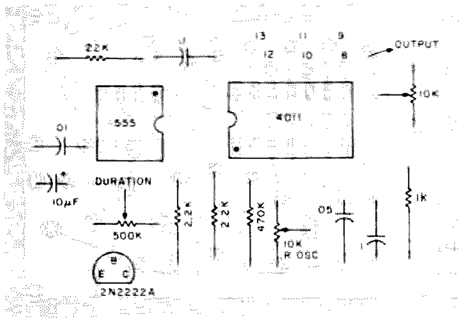

Fig. 3. MB-1 PCB layout, component side.

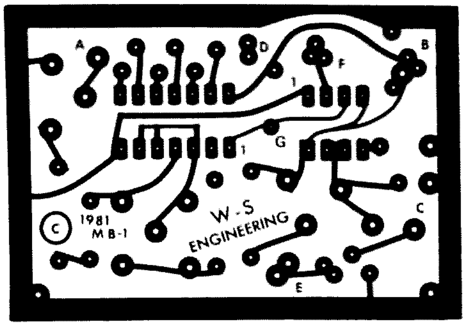

Fig. 4. MB-1 PCB layout, foil view.

tion. Timing can be set from milliseconds to hours. Note that C1 *must* be a high-grade, very-low-leakage electrolytic capacitor. Cheap or surplus capacitors have far too much leakage, and the circuit will not work with them.

The frequency of oscillation is controlled by the potentiometer labeled OSC. This potentiometer can be from several Ohms to megohms. The higher the value, the lower the frequency of oscillation. The output frequency is determined by the .05-uF capacitor and R-OSC. You can get this circuit to work up into the megahertz range, but above 500 kHz, stability becomes a problem for such a simple circuit.

A buffered input is available by using the 2N2222A. It also acts as an inverter.

The output level from the circuit for the astable and oscillator modes is controlled by the 10k-Ohm *output* potentiometer. As designed, the circuit will drive an 8-Ohm or greater speaker. In a reasonably quiet room, you can hear the audio output quite well.

Construction

Building of the circuit is very easy if you use the printed circuit board approach. Fig. 3 shows the pictorial layout of the PCB. Fig. 4 is a foil view of the actual printed circuit layout. Parts are not critical, but if you use cheap parts, the circuit performance is significantly degraded. Since this circuit is so small, it pays to use first-class prime parts.

Checkout and Setup

The fastest way to verify that your MB-1 works is to configure it as a generator. Hook up the board as per Fig. 2, function 1. Fig. 5 shows sample physical configurations, so you can make sure you have everything correct. Set R-OSC at mid-range and R-OUTPUT for maximum audio. After you apply Vcc, you will hear a tone from the speaker. If no output, vary the R-OSC and R-OUTPUT settings. If you still don't hear anything, start checking for bad ICs, incorrect wiring, solder shorts, etc.

Applications for the MB-1

I have found the MB-1 to be the most useful and cheapest little circuit I've designed. I have one in two different testers acting as simulated microphones. Another is used as a CMOS spare logic probe. I particularly like the audible feature so I can hook it to one part of a circuit and not have to look at it to know what is going on. And yet another is being used as a basic 455-kHz signal generator for rough applications. And last but not least, one is the original "beeper" for my Porta-Peater repeater.

You will probably think of more applications for this circuit after you have made a few. Figs. 2 and 5 should get you up and running. After you have put a few of these modules to work, you'll probably wonder how you got along without them!

I'm more than happy to answer any questions or provide any application assistance you may need. However, please provide an SASE. This greatly speeds up the answer process and keeps me from destroying the household budget.

W-S Engineering has a complete kit of all parts including a PCB for $12.00 postpaid in the U.S.A. (W-S Engineering, PO Box 58, Pine Hill NJ 08021). ■

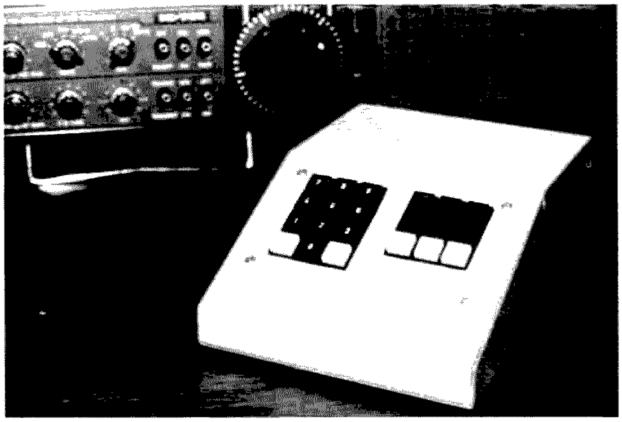
Remote-Control Your IC-701

Simpler than commercial controllers, this home-brew unit nevertheless features push-button band changing and frequency selection, scanning, and expanded coverage.

Glenn Williman N2GW
612 Auth Avenue
Ocean NJ 07712

Soon after purchasing my 701, I became interested in exploring the remote-control capabilities of the radio. I was not willing to spend the money for the manufacturer's unit, but I also did not need many of the built-in features obviously intended for use with their companion 2-meter set, the IC-211. Some cautious experimenting with the accessory connector on the rear panel led to the design of this relatively simple control unit which can perform all the operations I feel are necessary for operation on the HF bands. Basically, this unit can perform the following functions:

- push-button control of bandswitching
- frequency selection
- manual frequency scanning (fast or slow)
- extension of frequency range of standard IC-701

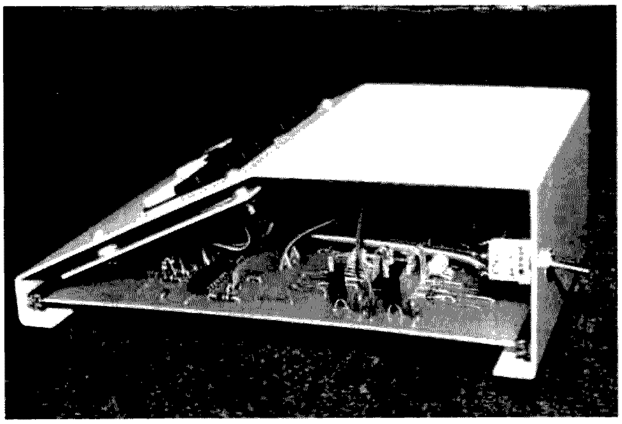


Front view.

Theory of Operation

In order to understand the operation of the remote-control unit, the requirements for controlling the IC-701 must first be examined.

The synthesizer in the IC-701 contains two presettable up-down counters which control the programmable divider in the phase-locked loop (PLL), one counter for each of the two vfo positions selectable on the front panel. The frequency data is encoded and read in serially, and in the normal mode of operation the data contains four characters, i.e., after the serial



Side view.

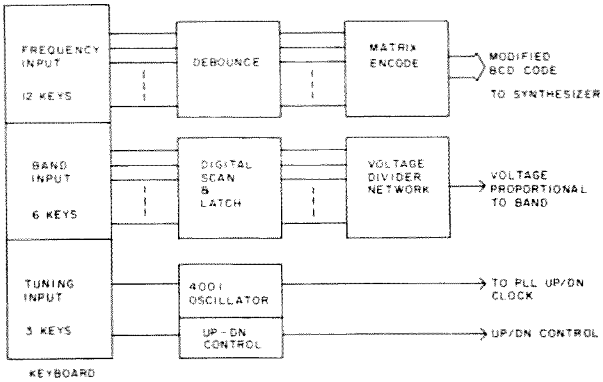


Fig. 1. Block diagram.

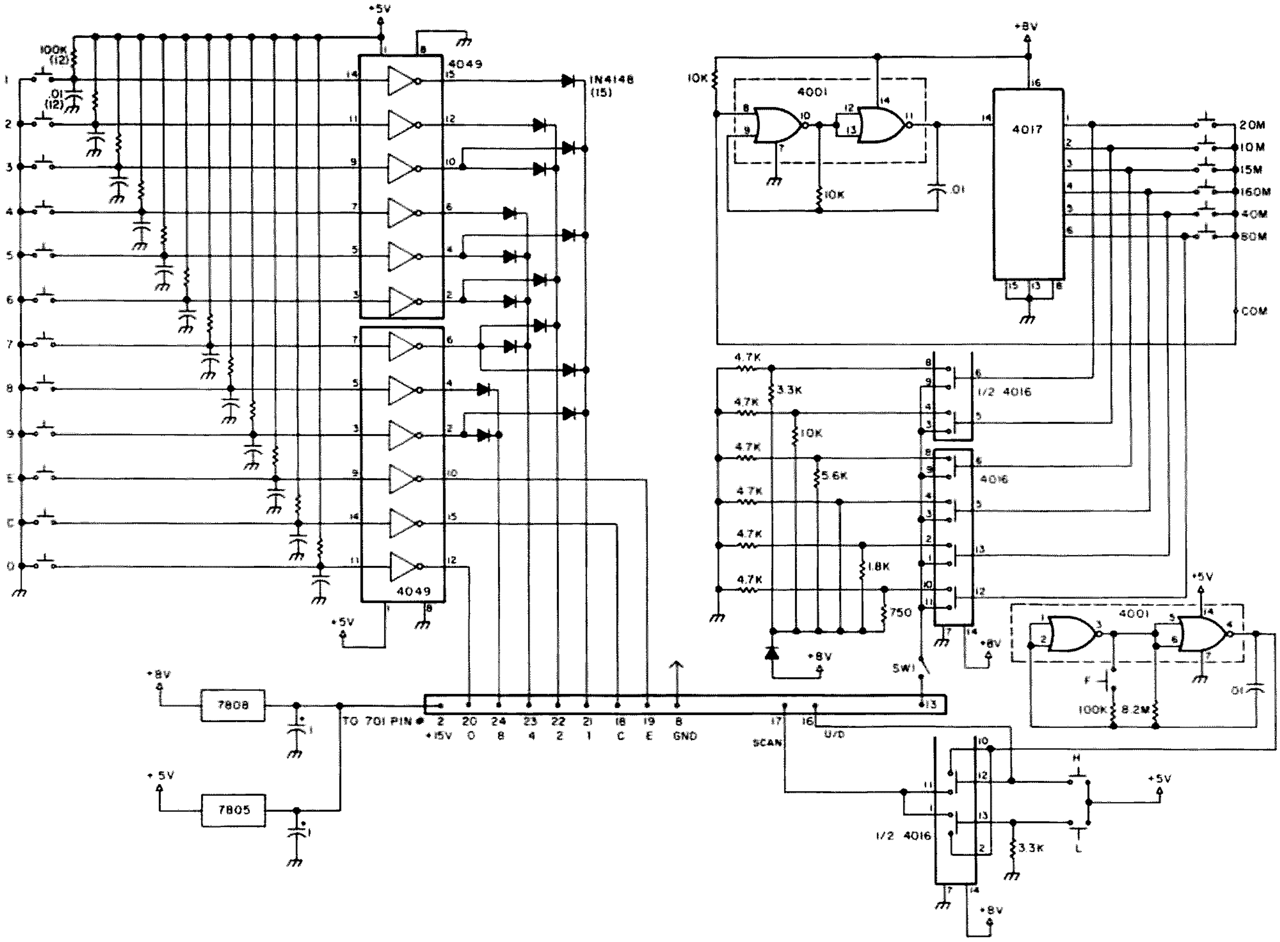

Fig. 2. Remote-control circuit.

data of the first four characters is entered, any succeeding data is ignored until the counters are again cleared.

Automatic bandswitching is accomplished by a stepping relay which is driven by a differential comparator. A front-panel switch selectable tap on a voltage-divider chain is compared to a similar voltage-divider chain switched by the stepping relay. When the two voltages are approximately equal, the relay is de-energized.

Therefore, two types of signals are required: a series of pulses to program the frequency of the synthesizer and an analog voltage proportional to the desired band. Fortunately, access to these signals (and many others) is provided at the accessory plug on the rear panel of the IC-701. The frequency programming inputs are always active and are terminated internally either by resistors to ground or within the PLL LSI unit. The analog voltage input for bandswitching becomes active only when the bandswitch on the front panel of the IC-701 is placed in the external position.

Circuit Description

Knowing the types of signals required and the further requirements which I imposed of using simple push-buttons and CMOS circuitry, the circuit shown in Fig. 2 evolved. A block diagram is shown in Fig. 1.

The frequency information is keyed in by twelve SPST push-button switches which are effectively debounced and encoded with a diode matrix.

As the switch is closed, in Fig. 3, the inverter is pulled to ground and any bounce is damped by the effect of the RC network. When the switch is opened, any bounce is again damped since as long as any of the damped or filtered bounce transients do not exceed $V_{CC}/2$, the switch is effectively debounced at the output of the inverter. For this circuit, 100k and .01 uF provided the necessary time constant for the switches used.

The debounced switches for 0 through 9 are then encoded into a BCD code. The exception is the 0 key. A separate line is used for the 0 character, rather than representing it as the absence of all other lines. This is presumably required since the PLL unit loads

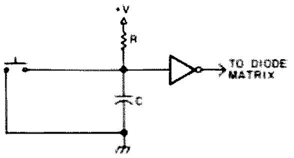

Fig. 3.

data serially one "digit" at a time with each keystroke. The C and E keys are control signals. The C key clears the counters, and the bottom edge of the selected frequency band will be displayed. The E key resets the counters and must always be used prior to entering digit information.

In order to achieve push-button control of the bandswitching, a digital scan and latch circuit is used. A 4001 RC oscillator running at about 4 kHz clocks a counter with decoded outputs (in this case a 4017,

since they were available). Assume the counter is stopped in state #1, and the clock is inhibited by the 10k pull-up resistor. Depressing any of the other five keys corresponding to states 2 through 6 pulls down pin 8 of the 4001, since outputs 2 through 6 are low, and enables the clock. The counter cycles until the high decoded output corresponds to the depressed key. Then the clock and counter are again stopped. Essentially what happens is that the selected output line of the counter is latched high by whichever key is momentarily pressed. This selected line also controls one of six bilateral switches (4016s). The input side of the bilateral switch is connected to a voltage divider whose voltage corresponds to a particular band, and the outputs are all common and fed to the band select input of the 701.

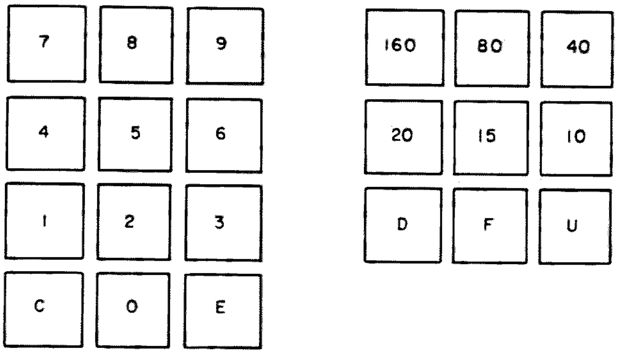

Fig. 5(a). Keyboard component layout.

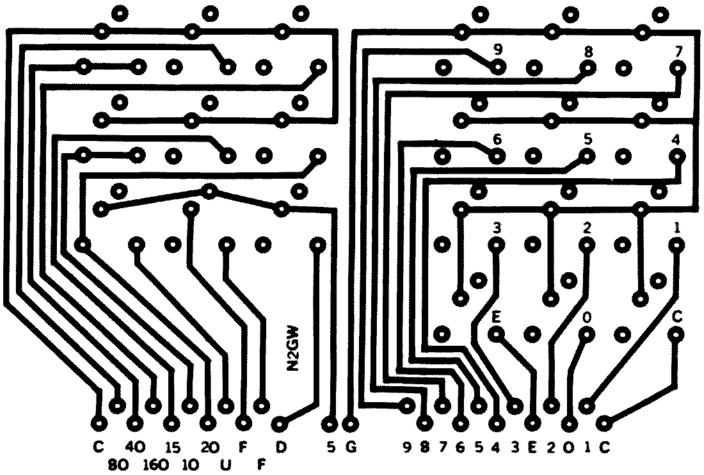

Fig. 5(b). Keyboard PC board.

Another 4001 RC oscillator serves as the scan clock input to the 701 in order to clock the divider in the PLL unit which tunes the synthesizer up or down in frequency. There are two inputs for this on the 701. Clocking one line will increment or decrement the synthesizer depending on an up or down signal on the other line. The RC oscillator is run at both a fast (500-Hz) and slow (10-Hz) rate so that fast and slow tuning can be accomplished. The H key tunes the 701 higher in frequency; the L key tunes lower in frequency, and the F key increases the tuning rate to a fast scan and must be depressed with an H or L key for fast tuning.

Power for the remote control is obtained from the 15-V-dc pin on the 701 accessory plug and is then regulated down to +8 V and +5 V for the different portions of the circuit. The up-down counters (fast and slow) and the frequency preset logic are all standard CMOS in the 701 and run at +5 V dc. The bandswitching voltage dividers in the 701 are fed with regulated +8 V dc, so this must be duplicated in the remote-control unit.

Construction

Two printed circuit boards were designed for this project, although a small IC breadboard will work nicely. One is for the keyboard (3" × 4.5") and one is for the control circuitry (6.75" × 4.5"). These are shown in Figs. 4(b) and 5(b). The push-button switches mount directly on the printed circuit board. Parts placement is shown in Figs. 4(a) and 5(a). The boards mount in an LMB type MDC 752 modular console. Ribbon cable (12-conductor) is used to connect the remote control to the accessory plug for the IC-701.

Operation

The layout of the keyboard with the band-switching and tuning keys on the right side and frequency selection keys on the left side lends itself to easy operation. Typical usage of the remote control goes like this:

1. Change band using one of six band select keys.
2. Enter particular frequency, e.g., 21.320.0, by using the 12 frequency select keys (sequence keyed in this example would be E3200).
3. Tune up or down (fast or slow) using the 3 frequency scanning keys (below band select keys).

Changing from one band to another and moving from one end of the band to the other can be done con-

NOT JUST ANOTHER REGULATED POWER SUPPLY!

The **FASTRAK**® model 2001 voltage regulator module is ideal for making reliable power supplies in a jiffy. Use it to power your mobile rig, other **FASTRAK**® series modules or as a general purpose bench supply.

- ▶ Component selection sets output voltage (3.3 to 400 V dc) and current capability (5 mA to 100 A). Over voltage protection and remote shutdown included. Uses no ic's.
- ▶ One evening assembly using 2 × 3.6 inch pc board and comprehensive instructions supplied.
- ▶ Price: $10.80

Price includes: glass-epoxy, etched, plated, drilled pc board; instruction manual; postage in U.S.A. (Ohio residents add 5% sales tax).

Send $1.00 for illustrated **FASTRAK**® product catalog and refund coupon.

P E I
PROHAM ELECTRONICS INCORPORATED

(216) 951-2110

siderably faster than by manual tuning, and with no transmitter tuning, the capability for instant QSY becomes more realizable.

There are several interesting operating tricks which can also be accomplished with the remote control.

1. The RIT, once turned on, will not be defeated when tuning with the remote control, as it will with the manual tuning control.

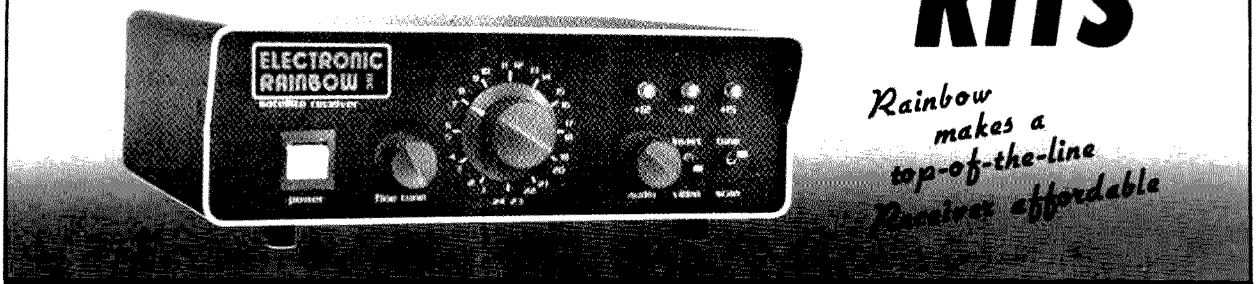
2. Pressing "E" and "1" simultaneously and releasing the "E" first will add 1 MHz to the displayed frequency; however, the display will only change on 20 meters and the display will indicate 15.xxx.x.

The following is a list of the expanded coverage that is available:
160m—1.000.0 to 2.999.9;
80m—3.000.0 to 4.999.9, MHz will not display "4";
40m—7.000.0 to 7.999.9;
20m—14.000.0 to 15.999.9;
15m—21.000.0 to 22.999.9, MHz will not display "22";
10m—no expanded coverage.

There are obviously other features that could be built into the remote control. Memory would be a "nice-to-have" addition and really not that hard to do although the sequential (serial) data input requirement does complicate things somewhat. I don't miss additional memory, over the two in the 701, but then again I didn't miss the remote control until I began using it. The ability to instantly move to different frequencies around the band is the most useful one for me and it has become an operating convenience I wouldn't be without.

Keys for the keyboard and circuit boards are available. Please enclose an SASE for details. ■

SATELLITE TELEVISION RECEIVER KITS



The Electronic Rainbow Receiver consists of a receiver with an external down-converter that mounts at the antenna, feeds the voltage to the LNA through the coax cable. The 4GHz signal is down converted to 70 MHz and is fed through the RG59/U coax to the receiver.

Rainbow Kits are supplied with simple step by step instructions. All the circuits that you need expensive test equipment to do are pre wired and tested. All printed circuit boards have the outline of each part printed on them.

RECEIVER FEATURES
Built in RF modulator • Detent Tuning-3.7 to 4.2 GHz • Variable Audio-5.5 to 7.5 MHz • Invert Video • Channel Scan • Voltage monitoring • Meter output • Remote Tuning
SPECIFICATIONS:
Single Conversion Image Rejection Downconverter • Threshold 8 db CNR • IF Bandwidth 24MHz • Output IV Audio and Video • IF Frequency 70MHz • Video Bandwidth 4.5MHz • Size 3½"Hx8½"Dx11¼"W

Complete Satellite TV Receiver
KIT #1 — Contains:
- Mainboard • Tuning Board • Downconverter Board • Modulator Board
- All parts needed to complete receiver
- Down Converter built in case.
- Cabinet, attractive black brushed anodized metal with silk screened front and back for a professional look
- 70 MH2 Filter is pre-wired and tested.
- Complete instruction Manual. **$395.00**

KIT #2 — Board Kit Contains:
- Main Board • Tuning Board • Downconverter board • Modulator Board
- Parts List, assembly and alignment manual
- 4GHz local oscillator and 70MHz filter is pre-wired and tested. **$129.00**

Instruction manual. Contains printed circuit board layouts, parts placement, and alignment instructions. **$25.00**

Automatic Beam Aimer

Here's the scoop on adding set-and-forget convenience to your rotator control. Works with most common control boxes.

Guy Slaughter K9AZG
753 W. Elizabeth Drive
Crown Point IN 46307

I have a smart knob in my shack. It looks like any other dumb old pointer knob sticking out of a black box, but it's really quite clever. Turn it to a given beam heading, and it makes the Cushcraft tribander atop the tower outside my house rotate to that same direction and stop there, all by itself.

I built its prototype originally for my sightless friend, W9PBS, who until then had a problem knowing which way his four-element monobander was aimed. The voltmeter needle on his Ham IV rotator control that usually reads out the direction his beam is pointing is worthless to him, of course. It was while mulling over the problem of converting that analog needle's silent message into something more useful that I came up with the idea for the smart knob. And I liked it so well while debugging it and burning it in on my own operating table that I had to build one for myself.

That's because my own DC-45 rotator control, identical with the Ham IV's and the control for the CDE's big antenna whirler, the Tailtwister, requires holding down both a brake release and a direction button while the beam is swinging from one compass point to another. This can take as much as half a minute for a 180-degree direction change. The smart knob, on the other hand, requires only a quick twirl to the desired beam heading and it does the rest itself, bringing the antenna around to the target while I tweak my transceiver tuning to peak that rare call up out of the mud and prepare to enter it in my log.

If you have a CDE rotator, I think you'd enjoy a smart knob, too. Mine's been in use for many months now without ever rebelling at its task. So has the one in daily use by W9PBS, who actually switches it between two separate Ham IVs, driving 15- and 20-meter monobanders mounted on separate towers.

The knob itself is fastened to the shaft of a 25k pot extending from a black box which, along with all the other parts and pieces inside except those scrounged from my junk collection, was bought at my neighborhood Radio Shack, for a total of less than \$50. The heart of the gadgetry inside the box is that pot and a 12-volt-dc power supply capable of providing 150 mA or so (see Fig. 1). The supply feeds two sections of an LM339 quad comparator chip, three 2N3904 transistors, and three 12-volt relays with DPDT contacts rated at three Amps. (See Radio Shack numbers in the Parts List.) But before we get into their functions, let's discuss the CDE rotator control system.

It is a conventional low-voltage ac capacitor-start motor whose direction of rotation depends on which half of its winding pair is energized. Though the light-duty CD-45, the medium-duty Ham IV, and the heavy-duty Tailtwister rotators have different braking systems and varying numbers of ball bearings in their innards, they are similar electrically and their control boxes are identical. Each contains the motor-feed transformer, the start capacitor, three push-and-hold button switches for brake release and directional control, and the direction-indicating circuitry. That circuitry consists of a power supply which provides 13 volts dc, a voltmeter to read it, and a calibration pot.

Inside the motor housing there is a variable resistor shunted across the floating-ground, 13-volt supply (and connected to it by rotor cable terminal posts 3 and 4 on the back panel of the control box). The movable arm of that remote resistor, mechanically linked to the motor rotor, is chassis-ground, cabled to terminal post 1 on the control unit.

The resistor is tied into the direction-indicating voltmeter circuit so that the meter reads full scale—13 volts—when the rotor is fully clockwise, zero volts at full counterclockwise, and 6½ volts at the halfway

point. The voltmeter face is calibrated accordingly, north at half scale, south at full clockwise and full counterclockwise, with the other points of the compass in between.

And that's where the smart knob comes in. If we connect the outside terminals of its 25k pot across binding posts 3 and 7 on the rear apron of the control box (shunting the rotor-feed wires already there), the pot will be in parallel with the 13-volt, direction-indicator supply, and the pot's center terminal will show a voltage to ground proportional to the difference in relative settings of the pot and the rotor-mounted resistor.

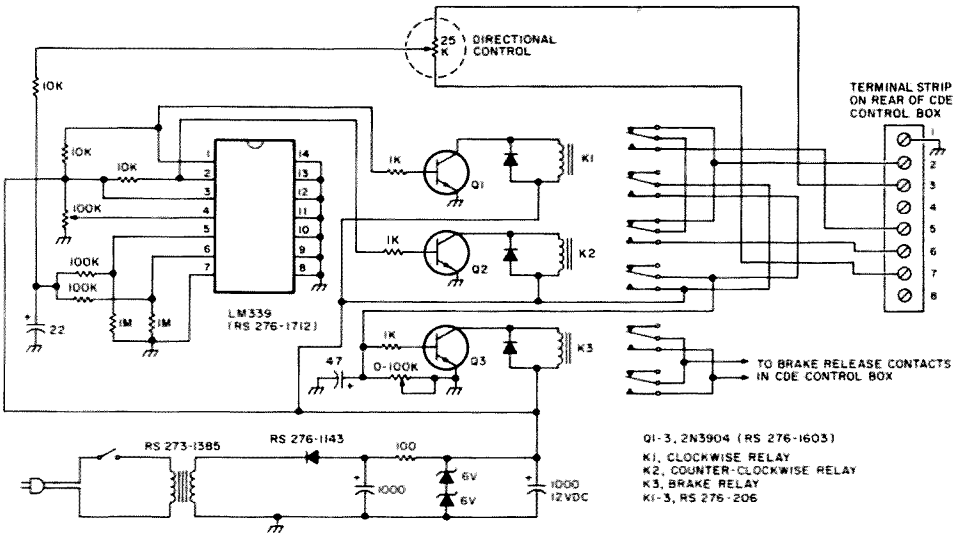

Fig. 1. Rotator control schematic.

With the rotor turned due north so that 6½ volts appears on the voltmeter, turning the smart knob's pot to half rotation—map north as indicated by the pointer knob, straight up—will bring to zero the voltage between its center terminal and chassis ground. Now rotate the pot clockwise, and that zero voltage will climb toward plus 6½, depending upon the degree of rotation. Turn it counterclockwise, and the voltage will fall back to zero at the midsetting, then begin a negative climb to −6½ when it's at full counterclockwise.

That's the secret of the smart knob's intelligence. All we need to do now is harness this intelligence to control the rotor motor and braking circuit so that our beam points wherever the knob tells it to.

Fig. 1 shows how the center terminal of the 25k linear-taper pot feeds two sections of the comparator chip so that one senses positive voltages, the other negative. Because each turns on a switching transistor whose collector current flows through relay coils, one or the other relay is pulled in whenever there is a difference in rotation angle between the smart knob and the beam rotor.

The relay contacts parallel the push-button switches of the rotor control box, thus energizing the brake and rotor motor, which swings the antenna to the direction called for by the smart knob; then the contacts open to hold it there. They are so interconnected that even a component failure or human error cannot trigger simultaneous clockwise and counterclockwise rotation. And there is a time-delay circuit in the brake-release relay's switching-transistor circuitry ensuring that the rotor—and the heavy load it carries—coasts to a stop before the brake is reapplied, thus averting the tower-twisting, rotor-ruining torque that the inertia of a suddenly-braked antenna can exert.

Parts List

1 cabinet (270-453)
1 transformer, 12 V, 300 mA (273-1385)
3 relays, 12 V, DPDT (276-206)
1 on-off switch (275-612)
1 package (2) zener diodes, 6 V (276-571)
1 25k pot, linear taper (271-1715)
2 100k minipots (271-220)
1 package (15) 2N3904 transistors (276-1603)
1 quad comparator LM339 (276-1712)
1 14-pin dip socket (276-1999)
2 1,000-μF electrolytics (272-957)
1 47-μF electrolytic (272-1027)
1 22-μF electrolytic (272-1026)
1 3-Amp rectifier diode (276-1143)
1 PC board, 4½" × 6" (276-1394)
1 package push-in terminals (270-1394)
1 package (50) diodes (276-1620)
3 10k, ¼-Watt fixed resistors
2 100k, ¼-Watt fixed resistors
2 1 meg, ¼-Watt fixed resistors
4 1k, ¼-Watt fixed resistors
1 length, (two, three feet) eight-conductor cable*
1 knob, pointer, junk-box type

*If you've got a rotator, you must have some cable somewhere, probably hanging in the garage. My Radio Shack doesn't stock it. The other parts will add up to around $45, if you buy them all new. Happy knobbing.

The component values shown provide a variable braking delay of about two to five seconds, adequate for my tribander and the heavier four-element monobanders used by W9PBS.

There is one small limitation. Because the voltage signalling the counterclockwise comparator to turn on its switching transistor falls to zero when antenna rotation approaches full counterclockwise south, and because even a smart knob requires a small fraction of a volt to sense, counterclockwise rotation will stop about 5 degrees from due south. But that's no big deal. Most beams have 60-degree lobes; you still can nudge the antenna the rest of the way with the manual push-buttons, or you can tell the smart knob to go full south clockwise where it has lots of voltage to sense. And it will.

There are no particular construction hints to pass along. Everything is dc and, therefore, lead lengths and dress are not a problem. I used perfboard and wired point-to-point because I'm not into printed-circuit fabrication. On one of the

smart knobs that I built, I used an eight-terminal barrier strip to wire it to the CDE control box, and on others I chassis-mounted six-contact female sockets so they could be unplugged from the rotor control box for testing and fiddling.

However you wire yours to the CDE control, there is a small bit of surgery required: You need to shunt a two-conductor cable across the brake-switch contacts inside the CDE control box and bring it out to the smart knob box. There is plenty of room to work inside the rotor control, and the plastic cabinet can be flexed enough to pass the cable between it and the chassis if you don't want to drill it for a connector socket.

If you use a plug and socket for this, be sure the brake contacts are connected to the female half of the connector, because the brake wires are hot with 120 V ac.

With the smart knob built and connected to the CDE control box, disconnect the brake-energizing cable so that the antenna won't be swinging back and forth as you adjust the pick-up-dropout points of the switching transistors by tweaking the 100k minipot feeding pin 4 of the comparator chip. Once you have that minipot properly set so that the device neither hunts for a null nor fails to respond to a 3-to-5-degree rotation of the smart knob, you can loosen the pointer-knob set screw on the 25k pot shaft to line it up at due north when the antenna is pointing due north.

Having thus compensated for any discrepancy between zero voltage at the pot's wiping contact and its precise half-resistance setting, you will find calibration is remarkably accurate at all points of the compass. ■

TUSA

A WHOLE NEW WORLD OF TV VIEWING WITH TUSA'S NEW MODEL CVU-40, 40 CHANNEL CABLE TV CONVERTER

Receive all the EXTRA CABLE TV "MIDBAND" & SUPERBAND CHANNELS on your UHF DIAL.

Eliminates the need for renting or leasing. This stable and reliable system converts extra cable TV channels so they can be received on the UHF tuner of your TV set. Provides the extra midband and superband channels now distributed by most cable companies. Channels 2 to 13 can also be seen directly on the VHF portion of your tuner.

Use of this unit may be subject to rules by your local cable TV Co.

Life-Support System for HTs

At home or in the car, this do-it-yourself charger and accessory box could be the best friend your handie-talkie ever had.

For the first couple of weeks after you buy your 2-meter handie-talkie "brick" (Tempo, Icom, Yaesu, etc.), it is sort of fun to plug and unplug the unregulated charger so that the nicad battery pack stays at full charge. After that, though, the newness wears off and it is just a pain in the lower backside to try to guess at how long you ought to leave the juice on before you boil the cells dry. Not only that, but you are never really sure whether you have given the battery pack full charge or whether you are consistently undercharging the nicad pack, a notorious cause of nicad deterioration.

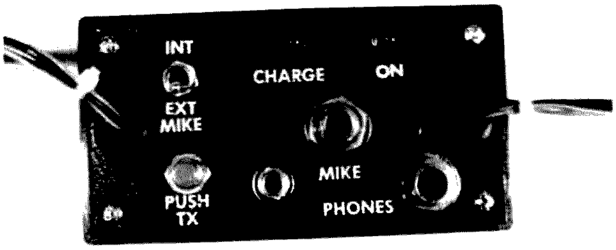
In addition, it would be sort of nice to be able to operate mobile with your brick and use the same mobile speaker and microphone that you use for all your other mobile equipment plus the mobile's battery-generator charging system. The brick box described here will solve these problems and perform the following functions:

1) Regulates the voltage and limits the current from the factory-supplied wall charger so that the nicad batteries in the brick may be left on charge for as long as you like without overcharging.

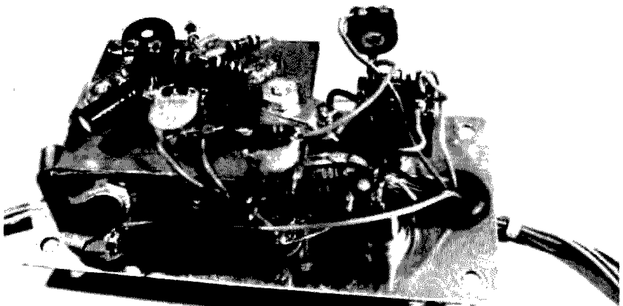
2) Allows the car (or boat, or snowmobile, or aircraft) battery-charging system also to charge the brick batteries with a regulated, current-limited circuit.

3) Permits you to plug in a mobile microphone and provides an amplifier-matching circuit between microphone and brick that is adjustable for exactly the right amount of deviation.

4) Allows the speaker amplifier in the brick to drive an



The completed brick box.



Inside view of the brick box showing unique "cobweb" construction.

external mobile speaker (with an option to install a speaker-driver-amplifier for higher power output) or a set of high- or low-impedance headphones.

5) Permits you to plug in to an already-existing mobile installation such as a private aircraft audio panel or a VHF-FM boat system and use the microphone/speaker/headphone setup in the mobile craft.

6) All these goodies cost less than $10 (plus an extra $5 for the high-power speaker amp).

Here are the ground rules for using this article: Most of the parts are available from any well-stocked ham store or "hobby-shop" electronics place. You may freely substitute for any of the parts. None of the parts values is really critical—a variation of ±20% should never really be noticed. Also, this article was written using the Tempo S1, and interfacing with standard commercial FM microphones and aircraft microphone-headsets (carbon or amplified dynamic). Other rigs and other microphones may require modifications of the mike amplifier circuit as shown later.

Regulator

The power supply regulator must perform two functions. First, on a deeply-discharged nicad battery pack, the regulator must limit the charging current below approximately 200 mA. Limiting the charging current in this manner prevents the cells from outgassing and drying out the electrolyte. Second, the charger must limit the end-charge voltage to the cells to approximately 1.37 volts for each cell, at which point the cells may be allowed to trickle-charge at this voltage indefinitely.

The current limiting may be done by either of two methods. First, if the wall charger itself is one of the "12-V, 50-mA" variety, no external limiting will be necessary. The wall charger itself provides the necessary current protection by its design. However, a fully-discharged 450-mAh battery will require over 9 hours to fully recharge, so you may wish to consider the alternative fast-charge circuit described a little later.

For those using a current-limited wall-pack charger, the circuit shown in Fig. 1 will regulate the final trickle charge voltage to 1.37 volts per cell, or an output of 11.6 volts into the Tempo S1 CHG jack. (1.37 × 8 cells + 0.7 volts, to compensate for one silicon diode inside the S1 in series with the charger line.) The basic circuit uses a 7805 (or 78M05 or 78L05) regulator, with a 1k variable resistor used to set the exact output voltage. To set the output voltage accurately, connect a 470-Ohm resistor across the 11.6-volt regulated output and adjust R1 (the 1k variable) for exactly 11.6 volts on an accurate voltmeter across the 470-Ohm resistor. The value of C1 (1000 μF) is not critical at all, providing that there is less than 150 mV ripple on the output with the 470-Ohm resistor attached. Up to a point, adding more capacitance to this point increases the charge rate (milliamperes) of the wall charger. I found 1000 μF to be the optimum value; do not go below 0.1 μF or the regulator will become unstable.

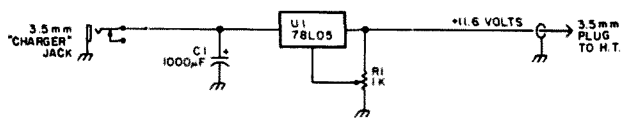


Fig. 1. The basic brick-box charger-regulator.

High-Power Regulator

In the event you can get your hands on a wall power pack with more output or for those who are going to use the almost unlimited current available from an automotive (or boat, or aircraft, etc.) supply to recharge the brick batteries, some method of current limiting must be employed to ensure that the nicad battery pack does not overheat due to excess charging current. Incidentally, for those of you looking for a very inexpensive high-current 12-volt wall-pack-style charger, look in the auto-supply stores or the automotive department of the larger discount houses for a "cold-weather battery maintenance charger." These little rascals *look* just like a low-power calculator wall pack, with one end terminated in a cigar lighter plug, but the fact of the matter is that they put out 12 volts at a whopping 300 mA. Don't forget the 1000-μF filter capacitor, though, because these high-power wall packs have a pretty raw, rectified ac waveform.

The trick to use to keep the maximum available current below 200 mA is to use a 78L05 for the regulator called out above. The 78X05 is actually a whole family of regulators where X defines the normal maximum current available. If X = L (78L05), normal current maximum is 100 mA; if X = M (78M05), normal current maximum is 500 mA; and if X = nothing (7805), the current available is 1 Amp.

Now, the internal current-limiting circuit in these ICs sets the current-limit point to about 150% of the maximum normal current, so if you use a 78L05 as your voltage regulator IC, the maximum current that your nicad pack can draw is approximately 150 mA, well within the maximum charge capacity of your brick's nicad pack.

Since I had planned to use the brick box in aeronautical mobile use in addition to use with a high-power wall-pack charger, not only did I use the 78L05 as my regulator, but I also supplied both a 3.5-mm jack on the brick box to plug-in the

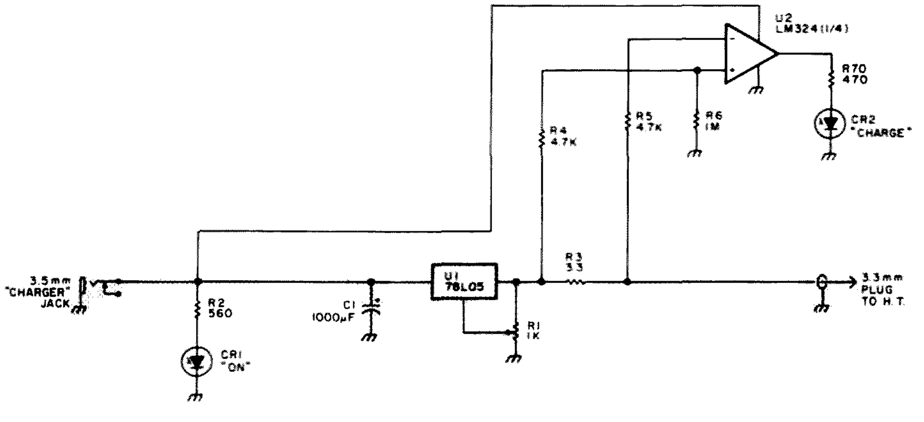

Fig. 2. Adding charge-indicator circuitry.

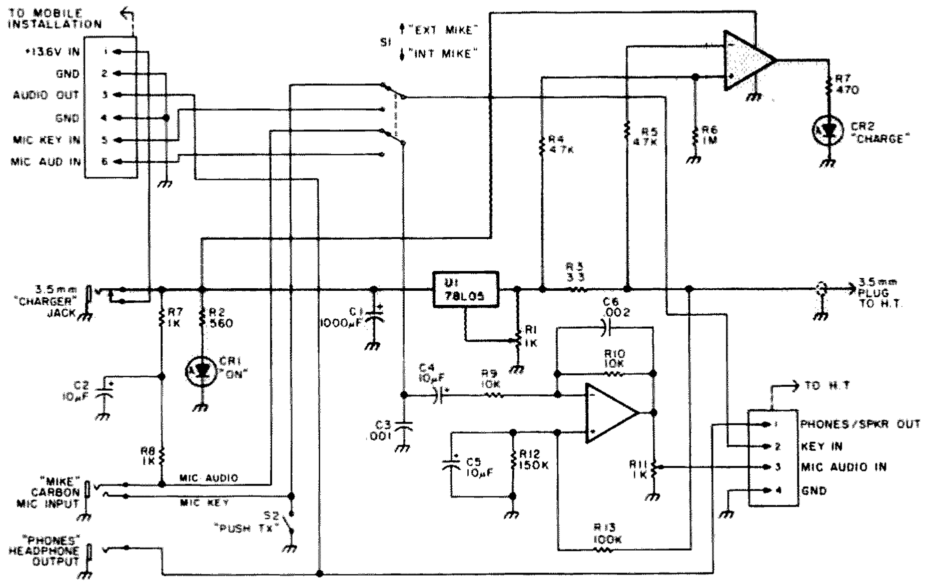

Fig. 3. The deluxe mobile-base brick-box schematic.

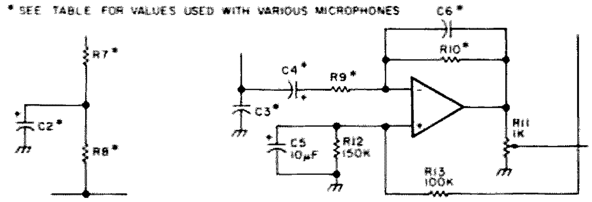

Fig. 4. Parts changes for various microphone types. See Table 1 for values.

wall pack charger and a cable connection to a molex®-type connector for attachment to the aircraft electrical system. As we shall see, using a 6-pin molex connector allows me to use the mobile microphone and speaker/phones, as well as the aircraft battery-charging system.

Charge Indicators

So far, we have a nicad battery pack charging system that will accept a low- or high-power wall pack or a battery-generator automotive-type system. The first refinement to make will be a pair of LED lamps. One of the lamps will tell us when power is being supplied into the charger and the second lamp will tell us when the end-of-charge cycle of the nicad pack has occurred. The first lamp is easy: an LED and a resistor (R2) will tell us if our wall pack or auto system is plugged in. The second (end-of-charge) lamp requires a little more circuitry.

The heart of the charge lamp is a high-gain op amp (LM324) used as a comparator. This circuit is shown in Fig. 2. The type of op amp is not critical, either. The common 741 or any other *true* op amp may be substituted. The so-called Norton (LM3900/MC3401) op amps may be used, but you are on your own for the circuit modifications which are necessary.

The 3.3-Ohm resistor (R3) introduces a negligible voltage loss to the charging circuit, yet drops more than enough millivolts for the op amp to work with. The presumption is that when the charge current drops below 20 mA, the nicad pack is fully charged. At this current, the 3.3-Ohm resistor drops about 70 mV. The op amp senses this voltage drop and when the voltage drops below 70 mV, the charge light extinguishes. R6 (1 Meg) sets the current level at which the charge light turns on and off; if you wish for the light to turn on and off at another current level, attach a resistive load of your chosen value from output to ground and select R6 until the light just flickers. Remember, now, when this lamp is *lit*, the nicads are *charging* and when it is *dark*, the nicads are either *disconnected* or *fully charged.*

Microphone Amplifier

The second refinement is a matching circuit shown in Fig. 3 which will take the output of a standard mobile microphone (carbon or amplified dynamic) and massage it to fit the input requirements of the brick. (Note: for those of you using straight low-z or high-z dynamic, ceramic, or crystal microphones, see Fig. 4. The various values for Fig. 4 are shown in Table 1.) Since the requirements of the brick are a microphone voltage of some 200 millivolts peak-to-peak and the output of the carbon/dynamic microphone biased with 10 mA (by R7/R8) is about 500 millivolts p-p, the op amp circuit shown will provide an output somewhat in excess of requirements and can be adjusted to the proper deviation level with R11. The rationale here was not so much that we *had* to have an op amp to drop a 500-mV level to 200 mV, which could well have been done with a simple resistive network, but we had one leftover op amp from the IC used in the charge-light circuit, and the op amp is necessary for the alternate mike circuits shown in Fig. 4.

Once again, since this brick box was intended for use as both a base-station patch box and a mobile interface unit, a microphone jack was installed on the brick-box chassis, plus a pair of wires to the molex connector for attachment to the aircraft microphone and PTT switch. A switch was included on the brick box so that either internal microphone (the brick-box jack) or external microphone (through the molex plug to the mobile mike setup) could be selected. This was done so that the

Microphone	C2	C3	C4	C6	R7	R8	R9	R10
Carbon	10 μF	0.001 μF	10 μF	0.002 μF	1k	1k	10k	10k
Crystal/Ceramic	Open	10 pF	.005 μF	20 pF	Open	Open	1 meg	1 meg
Low-Z Dynamic	Open	0.001 μF	10 μF	220 pF	Open	Open	10k	100k

Table 1. Values for various microphone types.

pilot of the aircraft (WB6BHI) or the back-seat passenger (WD6EWI) could access the 2-meter rig separately and independently.

The remainder of the elementary brick box is quite simple. The speaker output of the transceiver is run to both the headphone jack in the brick box and a wire to the molex plug for external mobile speaker.

Speaker Amplifier

Although this concludes the construction of the elementary brick box, several comments from my fellow hams led to the first major modification of the box. Since my major application of the box was for airborne use and I was feeding the puny 1/2-Watt speaker signal out of the brick into a 10-Watt airborne cabin speaker amp, I never noticed how poor the speaker audio really was. A few tests convinced me that a speaker amp of some sort was in order. Since the most common high-power chip in general use and availability today is the LM383, I chose to use this fine device. Although the design is very straightforward, I recommend that you heat-sink this device to the biggest piece of metal you can find. In fact, if I were going to include this circuit in my own brick box, I would undoubtedly use the metal chassis cover for the heat sink. The tried and proven circuit of the speaker amp is shown in Fig. 5.

Conclusion

The brick box has been in operation for almost a year now with no serious problems. My S1's batteries have always given me the expected service when charged by the box and mobile service has been beyond any hopes I ever had. (*You* get up to ten thousand feet and call CQ on .52 simplex!) My thanks to WD6EWI for his comments and criticism and N6AUB for his patient on-the-air testing. My additional thanks to the hundreds of hams between Grass Valley, California, and Oshkosh, Wisconsin, who gave us hints and suggestions for improvement during our recent aeronautical mobile cross-country. ■

OK MACHINE AND TOOL

IC INSERTION/EXTRACTION KIT

includes DIP IC extractors and inserters to accommodate all ICs from 14 to 40 pins. Tools that engage conductive surfaces are CMOS safe and include grounding lugs. Stock No 13309 $37.74

SOCKET WRAP ID

DIP socket sized plastic panels with numbered holes in pin locations. Slip onto socket before wire wrapping to identify pins. Also write on them for location, IC part number, function, etc. Simplifies initial wire wrapping, troubleshooting and repair.

13295 14 pin; 13296 16 pin; 13297 18 pin; 13298 20 pin; 13299 22 pin; 13300 24 pin; 13301 28 pin; 13302 40 pin; 13303 36 pin

$1.82 per pack of 10

IC EXTRACTOR

One-piece, spring steel construction. Will extract all LSI, MSI and SSL devices with 8 to 24 pins. Stock No. 13313 $2.10

Special of the Month!

MEMORY SALE!

4116-3 200NS 16K Dynamic Ram Stock No. 47650 $2.10 ea. 8/$15.52

2114-L-3 300NS 4K Static Ram Stock No. 47640 $2.45 ea. 8/$17.84

2716 450NS 16K Eprom Stock No. 47632 $3.90 ea. Any Quantity!

PIN FORMING TOOL

puts IC's on their true row to row spacing. One side is for 300 centers. Flip tool over for devices on 600 centers. Put device in tool and squeeze

ONE TOOL DOES 8 Thru 40 PINS! Stock No. 11059 $12.95

MODUTEC

Miniclamp AC Volt-Ammeter allows singling one conductor out of many without disarrangement

SET of THREE $99.00

Stock No	AC Amperes	Price
13730	0-25A	$39.50
13731	0-50A	39.50

What?! Another Audio Filter Project?

Yup. And even the most modern receivers benefit from this QRM-crusher.

I got my hands on one of those toy transceivers a few months ago—the kind with a flea-power transmitter and a direct-conversion receiver—and for a while, I had a ball with it.

But slowly, some drawbacks began to manifest themselves—not so much in the rig, but inside my head, where ringing noises refused to go away. The receiver is quite sensitive and has a tremendous dynamic range but it has no agc (automatic gain control), so when you're tuning for weak DX signals and come across a Texas rock crusher . . . Well, I generally don't cherish corona flickering between my ears.

It slowly dawned on me that even my main station receiver, though it has a good agc system for CW, exhibits some other rather nasty habits which it shares with the little plaything receiver. And eventually, I began to think about doing something about it.

Unfortunately, most modern ham-band receivers—even the very good ones—do very little after extracting audio from the product detector, except to amplify it and cram it into a speaker or a headphone output. Many things can be done to audio to make communications a lot better, especially on CW.

The audio unit to be described is my second major effort in that direction. The previous unit, built about 1960, used vacuum tubes and weighed enough to keep my house and shack from blowing away in Hurricane Donna. That unit, described in a long article in *QST*,[1] offered peak clipping, audio selectivity, and volume compression, none of which was available in the receivers of that day—or in most 1981 models. There is one big difference. Modern receivers usually (but not always) have agc systems which work well with SSB and CW.

My new audio processor would have to be all solid state, like the rest of my equipment, and it would have to offer the same features as the original, with suitable improvements.

If you work contests or DX pileups on CW, you know that a 400-Hz passband sounds like you're listening to all outdoors, especially if you have experienced the good selectivity of the 100-Hz-and-under variety.

But selectivity has its trade-offs. Any sort of noise impulse is stretched. Key clicks, which sound like a small-arms fight in some Middle Eastern desert, become a rolling artillery barrage when they're stretched through a sharp filter. So, even with a good receiver agc, you still need to do something about the noise pulses before you introduce selectivity.

And, for those receivers without agc or only a poor agc, audio compression works wonders. Before good agc was developed for SSB and CW, a CW operator had to tune his receiver with one hand on the dial and the other on the rf gain control. Even with that kind of receiver (or with a modern direct-conversion job with no agc), one-handed tuning becomes possible when you use audio compression.

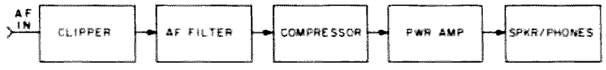

Fig. 1. Audio processor block diagram.

So, I decided my fancy solid-state processor must begin with a peak clipper, followed by a good stage of selectivity, followed by compression, and *then* (finally) by enough power to drive a loudspeaker and phones. It must be connected to the receiver only by a patch cord from the headphone or speaker output to the processor input, so that no modifications need be made to the receiver (see Fig. 1).

Clipping

Clipping and compression are terms which are often misunderstood. Clipping, for our purposes, is the process of whacking off any audio signal which exceeds some preset amplitude. The waveform is grossly distorted and lots of harmonics are generated in the process.

The clipping circuit chosen for this application is the familiar full-wave, series peak clipper (Fig. 2). It works like this:

Audio from the receiver is fed through a capacitor to a pair of small silicon diodes (1N914s or similar) in series, anodes connected together. A positive voltage is applied to the anodes, so that current flows through both diodes to ground through load resistors.

As long as those diodes conduct, they look like pieces of wire to the audio signal coming in from the receiver. But the moment a positive audio peak voltage becomes greater than the forward bias, the diode ceases to conduct, and the signal can't get any bigger in that direction. The negative half cycle, though, goes through because it only forward biases the diode even more.

But the other half cycle then collides with the second diode, with reversed polarity, and the other audio peak is clipped off. A good sine wave applied to the clipper comes out looking much like a square wave. Noise pulses, of course, also are clipped. How deeply the signal is clipped depends on how much bias voltage is applied to the diodes by the 10k pot. The voltage can be made so high that no clipping occurs, or so low that no signal gets through at all. The clipper can also be defeated by closing SW2 which shunts the audio around the diodes completely.

In use, the clipping threshold is set at some intermediate point which the operator finds to be comfortable. The setting will be affected, of course, by the audio gain control on the receiver.

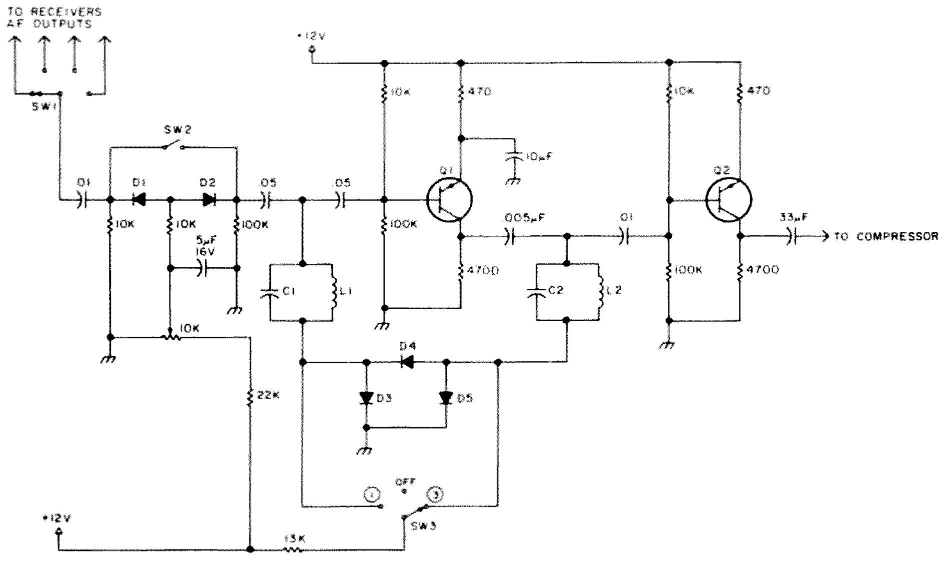

Fig. 2. Clipper-selectivity section of processor. Q1 and Q2 are PNP audio transistors such as the 2N3906. L1 and L2 are 88-mH telephone toroids. See text for C1 and C2.

Selectivity

The output of the clipper is fed to the selective circuit through a capacitor which blocks dc. Any of a variety of selective circuits could be used here, including the popular bridged-T active audio filters using IC op amps. I chose to use parallel-resonant 88-mH telephone toroids because I can change the resonant frequency simply by changing the values of the parallel capacitors. To change a bridged-T involves three capacitors in each pole of the filter. (See Fig. 2.)

The output of the clipper is applied across one 88-mH toroid tuned to 700 Hz with capacitors totaling 0.57 μF. Another blocking capacitor isolates the toroid from the dc on the base of Q1. The transistor amplifier restores the considerable insertion loss caused by the clipper and the toroid filter. Any handy transistor can be

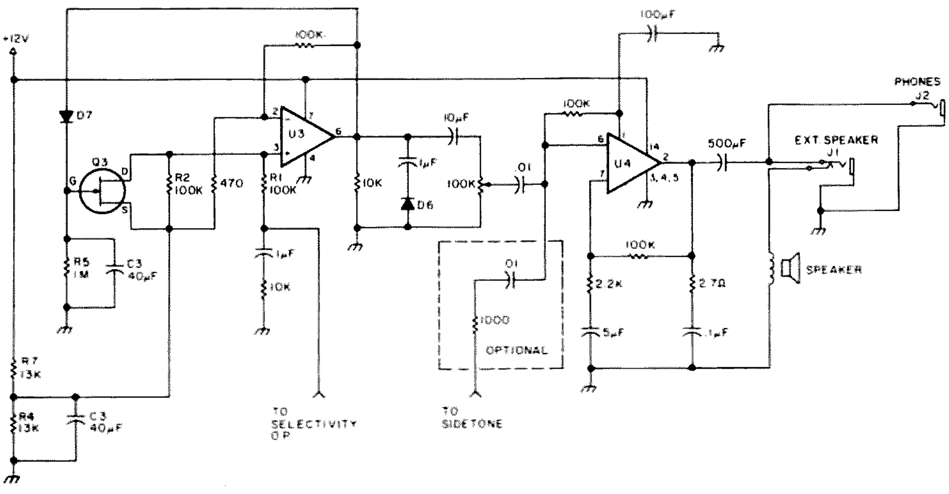

Fig. 3. Audio compression and power. Q3 is a 2N3819 FET or any similar audio FET. U3 is a TL081 FET op amp. U4 is an EC5700, ULN2277, or FE IC27. D1-D7 are 1N914s or similar.

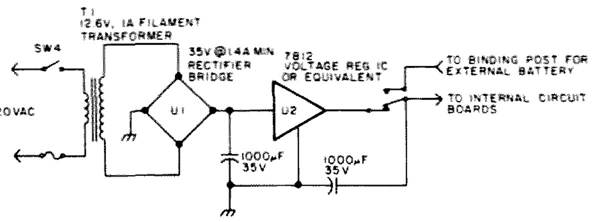

Fig. 4. Power supply suitable for the audio processor.

used, and the ones I used were junk box PNP silicons which were probably refugees from a Radio Shack red-tag sale. If you use NPNs or germaniums, be sure to make the necessary circuit changes, including polarity and bias. Almost any inexpensive audio transistor in a suitable amplifier circuit will do the job.

The output of Q1, taken from the collector, is coupled to the second toroid, tuned to the same frequency as the first, and again the insertion loss is restored by Q2. Actually, it is somewhat more than restored, and the output is ample to drive the next stage.

In operation, you can elect to use both toroids, for maximum selectivity, only one toroid for intermediate sharpness, or neither one, leaving you with only the selectivity of the receiver itself. Switching is done by means of diodes, so that signal leads can be kept on the circuit board, and not run to the front panel. With SW3 in position 2 (Off), neither toroid is in the circuit because its ground return circuit is open.

In position 1, positive voltage is applied to D3, making it conduct and become virtually a short circuit to ground, thus completing the toroid circuit. In position 3, voltage is applied to D5, thus grounding the return for L2. The same voltage turns on D4 which, in turn, turns on D3 so that both toroids are now in the circuit, for maximum selectivity.

Compression

Compression is a somewhat misunderstood term. Here it is used to mean automatic control of the audio gain so that the amplifier output remains virtually constant, despite large changes in the input level. The process does *not* distort the waveform of the signal. (See Fig. 3.)

In the circuit I chose,[2] the compression amplifier (U3) is a TL081 FET op amp, inexpensive and readily available. The output of the filter is fed to the non-inverting input of op amp U3, and its output is fed to the input of an audio power amplifier chip, U4.

The output of U3 is also fed to a voltage doubler formed by D6 and D7. This generates a positive dc voltage which is proportional to the audio output voltage of U3, and this dc voltage is fed to the gate of FET Q3.

The FET acts simply as a variable resistor. Note that audio coming out of the filter stage is fed to the top of a voltage divider composed of R1 and R2. The input of the op amp is taken from the midway point on this divider. The bottom half of the divider, R2, is paralleled by the source-drain circuit of the FET.

The ground return of the voltage divider is the center of another voltage divider, formed by R4 and R7, across the power supply voltage. This tap is also the ground return for the 470-Ohm resistor in the inverting input lead. This makes it possible to use only a single power supply for U3, rather than two.

With no signal applied to the input of U3, no output is generated, hence no voltage from the voltage doubler. The FET is biased to "pinch off" by the voltage across R2, which makes the gate negative with respect to the source.

When an audio voltage appears at the input of U3, a positive dc voltage appears across the voltage divider and this is applied to the gate of the FET via D7, opposing the negative bias and allowing the FET to begin to turn on. The more audio out from U3, the more positive bias, and the more the FET turns on, making its resistance lower and lower. The effect is the same as moving the input to U3 further toward the ground end of a volume control; it applies less audio voltage to the input, thus cutting back on the output. The result is excellent volume compression in which the output remains almost constant despite great changes in input level.

Some of the output audio is picked off by the volume control and fed to the audio amplifier IC, U4.

Audio Amplifier

A considerable variety of audio amplifier ICs is available. I used a ULN2277 for U4, which provides two Watts per channel, and I only used one channel. An LM386 could be used and will provide about half a Watt of audio to drive a small speaker beyond endurable volume. It costs about one dollar at ham supply houses.[3]

Power Supply

A regulated power supply (See Fig. 4) is used because the regulator IC provides excellent ripple filtering, not because anything needs a regulated voltage. The rectifier is a small, cheap bridge or it can be made up from discrete diodes rated at one Amp or more at 35 volts or more. The regulator chip will deliver one Amp, maximum, regulated, and that's probably three times the actual demand of the system. The output amplifier chip probably can be run directly from the unregulated output of the power supply, provided this does not introduce noticeable hum in the output.

Construction

Construction is straightforward and non-critical. I built the power supply into a corner of a small aluminum cabinet box, using a small piece of perfboard to mount the components. The board was mounted to the chassis with the small metal mounting lugs obtained by drilling them off old-style tie-point strips. This type of mounting is extremely convenient because it permits standing the boards on edge and provides for easy removal for service or modification.

The IC circuits were built on universal circuit boards.[4] One board was sawed in half, and the compressor and clipper built on one half, the output amplifier on the other.

The toroids were mounted on a piece of perfboard with dabs of five-minute epoxy, leads anchored to tie-points, and then the perfboard was bolted to the edge of another type of universal circuit board on which each cluster of four holes is connected together by a foil pad. This is useful for mounting the transistors and other components by their leads.

Each board was stood on edge and bolted to the chassis with brackets. But these should *not* be used for circuit grounds. Grounding each board directly to the chassis will probably result in ground loops which produce hum, noise,

oscillation, and all sorts of nasties.

Instead, use a common ground on each circuit board insulated from the mounting feet, and connect the circuit ground with a wire directly to the negative voltage tie-point on the power supply board.

Operation

After the project passes its "smoke test," you're ready to learn to use it. Hook it up to your receiver and hook up the output to a loudspeaker.

Set the volume control about one-fourth open, put the selectivity switch in the Off position, and turn the clipper on. Feed a steady signal into the amplifier. The tone from a 100-kHz calibrator will work fine. Adjust the clipping threshold, noticing that at the clockwise extreme of the pot, you get no signal output at all. At the counterclockwise position you get no clipping and at points in between clipping is apparent because of the change of audio quality of the clipped signal.

Flip in one filter section and notice that the clipped signal suddenly sounds clean again. The harmonics have been filtered out. The second toroid section won't seem to have much effect in this test—but it will in actual operation.

Now find a place on the receiver dial which is fairly clear of signals, turn off clipping and selectivity, and set the receiver volume control until you can just hear the crackle of background noise in the speaker, or to where you can hear a weak CW signal. Leave the volume control set, and tune across the band slowly, stopping to listen to each signal you come to.

Loud signals are no louder than weak ones, but you will notice that the background noise disappears while a strong signal is present. This is because the compression has reduced the overall gain.

Now tune away from the strong signal to a no-signal spot and listen. Notice that after a few seconds, background noise slowly becomes audible, as the compressor increases gain again. It has a fast-attack, slow-decay time constant.

Decay time is set by R5 and C3 in the gate circuit of the FET. Resistor and capacitor values are chosen to give a delay of several seconds so that the amplifier won't "pump" on a strong CW signal. Instead, it reduces gain in proportion to the average strength of the signal and keeps the gain reduced during the brief key-up periods between letters and words and even during brief pauses.

If recovery time were very short, band noise, weak QRM signals slightly off frequency, and other disturbances would appear in the background instantly whenever the desired station released his key—very tiring and disturbing to the receiving operator. Try it if you like, by temporarily replacing C3 with, say, a 0.47-µF capacitor.

Changes to Play With

The overall design of this unit is quite flexible and, since it is built in modules, with each section on its own circuit board, it is quite easy to experiment.

Various degrees of selectivity can be achieved, for example, by shunting the toroids with resistors, to broaden them, or by adding a third toroid for extreme selectivity. Various kinds of active audio filters can be substituted for the toroids. Skirt selectivity of the toroid filters can be improved by insertion of two 1N914s reverse-connected in parallel between the first toroid and the coupling capacitor to the base of Q1 (see Fig. 1). These are silicon diodes which will not conduct at all until forward voltage across the junction exceeds about 0.7 volts. Therefore, the base of Q1 won't "see" any output from the toroid until the voltage rises above 0.7 volts, thus effectively rejecting low-level QRM on the skirts of the filter.

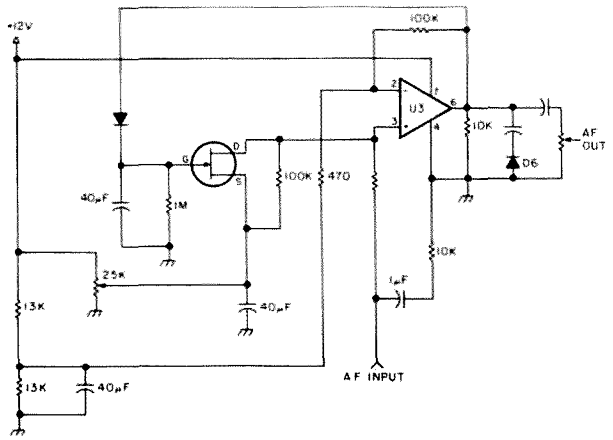

Fig. 5. Compression control modifications.

The compression threshold can be manipulated over a wide range, if desired, since compression does not begin on weak signals until they reach a certain minimum voltage. That's because the FET is pinched off and some of the bias must be overcome before the FET drain begins to conduct at all.

However, if the drain is removed from the R3-C4 tap (leaving the other components attached), and connected to the wiper of a pot, this delay of the attack can be changed at will (see Fig. 5). One end of the pot is connected to +12 V dc and the other end is grounded. When the wiper is grounded, the FET turns fully on, reducing the op-amp output sharply.

When the wiper is moved toward the top of the pot, the source becomes more and more positive. Hence, the gate becomes more and more negative with respect to the source, and more and more compression bias is required from the op amp to turn on the FET. It is possible to set the pot to provide compression on *any* signal, no matter how weak, or to prevent compression of any but the very stongest signals.

An S-meter can be built which will show the relative strength of received signals by measuring the compression bias (see Fig. 6). A simple FET voltmeter reads the bias generated by the op-amp output.

The unit can be muted for full break-in (QSK) CW operation if desired by us-

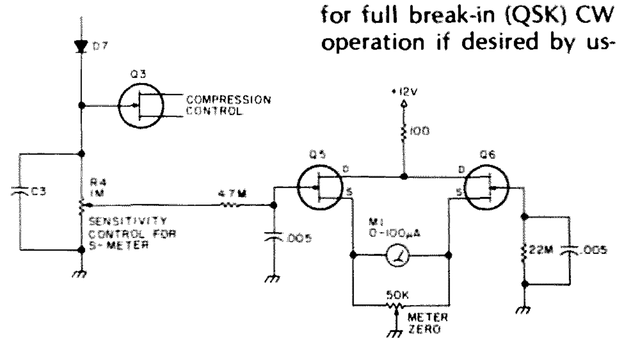

Fig. 6. Optional S-meter circuit.

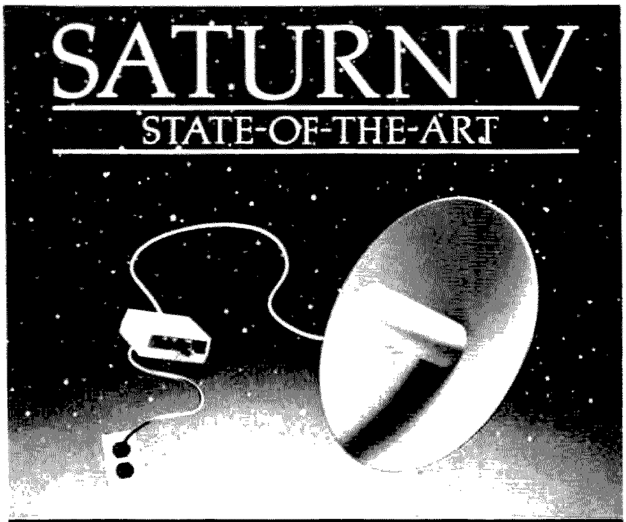

The Saturn V is a deep fringe microwave receiver for homeowners that are outside of the service area of local pay TV stations (i.e., HBO, Showtime). It is normally used within line of sight of a transmitting tower in a 50 mile range and is simply attached to your TV antenna mast. This unit is completely ready to install including all cable and mounting hardware. It is designed to be installed by the homeowner.

ing a transistor switch to clamp the clipper diodes when the key is down. The keying signal for the transistor can be a logic low or high picked off from a solid-state electronic keyer, such as the Accu Keyer, or by the relays of other keyers. See Fig. 7.

When the muting transistor is off, which it always is when the key is up, it has no effect on the operation of the diode clipper, but SW2 must be open for muting to function properly.

When the key is down, the transistor turns on to saturation. This offers a low-resistance path to ground for the dc bias on the diodes, effectively grounding both the diodes and the audio signals passing through them. Because of its lower junction voltage drop, a germanium transistor will work better here than silicon. Even so, muting is not absolute and some signal from the receiver gets through at low level. The circuit does not affect operation of the rest of the audio processor.

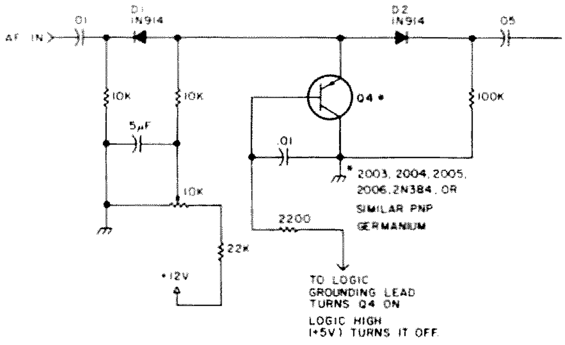

Fig. 7. Muting circuit added to peak clipper.

Sidetone can be injected into the amplifier when the key is down, making it appear in the same speaker which carries the incoming signals (see Fig. 3). Since the sidetone is injected after the clipping, compression, and selectivity, it is not affected by processor operation and can be set for any convenient pitch or volume.

Several inputs can be provided for the processor, selecting them by switch from the front panel. This makes it possible to use the processor on just about any receiver in the shack.

Auxiliary outputs often come in handy, too, for driving phone patches and similar uses. I provided mine with three front-panel headphone jacks—one of each of the popular sizes of plugs—so that any handy headphones can be plugged in without a hassle.

I built in a little two-inch speaker for convenience in testing and portable operation, but a phone jack is provided for an external speaker. Plugging in the external speaker mutes the internal one. Both speakers can be muted by a front-panel switch, if desired.

A back-panel switch can be added to allow operating the unit from an automobile battery for Field Day or emergency situations. The SPDT switch is connected with the pole to the internal +12-volt lines of the circuit boards. One contact is connected to the output of the 12-volt regulator chip. The other contact is hooked to a back-panel binding post which goes to the external battery. A second binding post should be provided to permit connection to the battery negative.

A 1000-μF 35-volt capacitor is connected from the pole of the switch to ground. It helps with the filtering of the regulator output and, when used on a car battery, it helps to subdue ignition and voltage regulator noises and alternator whine.

Troubleshooting

Troubleshooting the processor is as simple as troubleshooting can be. Nothing is critical as to value or adjustment, except that the tuned filter circuits must be on exactly the same frequency. Failure to operate properly will almost always prove to be traceable to a wiring error or a faulty diode, transistor, or IC chip, a solder bridge on a circuit board, or failure to solder a connection. ■

A Tuner for Antenna Fanatics

Anyone experimenting with antennas needs a darned good tuner. Construct this one and save your finals.

Various antenna tuner networks for the HF bands have come and gone over the years, but two forms have evolved as time-proven favorites—the Pi and T networks. The basis for the durability of these networks is a combination of electrical as well as constructional reasons.

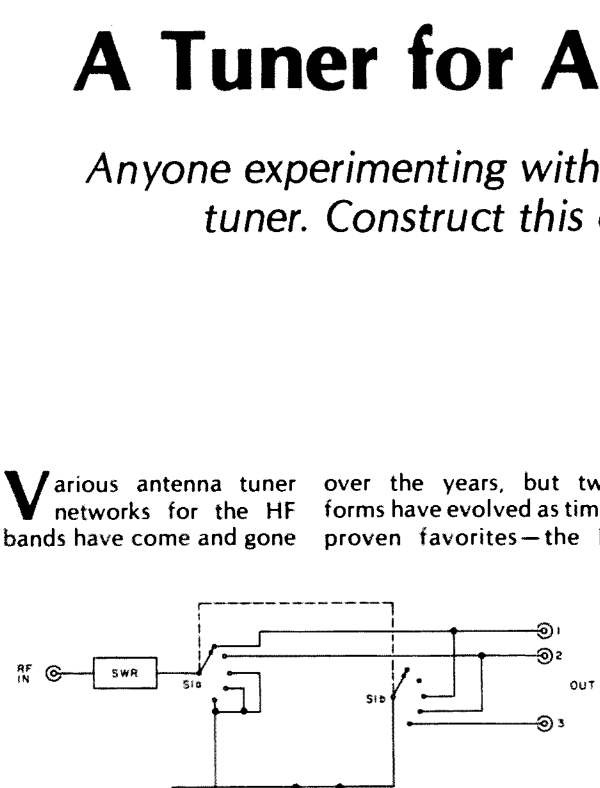

Fig. 1. Tuner circuitry. The S2 switch arrangement may appear complex, but wiring is not complicated nor are long lead lengths introduced, since most of the wiring is between switch lugs. Normally, a two-wafer switch would have to be used, although single-wafer surplus switches having a 5P3T action can be found. C1 and 2—at least 250 pF each, rated at 1.5 kV for 300 Watts, 2 kV for 500 Watts, and 4 kV for 1 kW; L—18 to 28μH, #10 or 12 wire; S1 and 2—Centralab PA-2000 series or similar.

The Pi network will not match an extreme range of impedances, but it is relatively easy to construct and adjust in operation. Its main disadvantage is that it requires considerable amounts of capacitance on the lower frequency bands when working into low-impedance loads. Usually, padding capacitors are required across the variable capacitors on the lower frequency bands when a high-power tuner is being constructed since 1,000- or 2,000-pF variable capacitors rated at 2 to 3 kilovolts are not exactly common items.

On the other hand, the T network does not require extreme amounts of capacitance even on the low-frequency bands when matching into the same or even greater range of load impedances than a Pi network will accommodate. The T network is, however, slightly more tedious to adjust and also to construct since the variable capacitors used must have both their stator and rotor sections above ground. The popular "Transmatch," by the way, is a basic variation of the T network.

But, why not have the best of both networks in a single multiband tuner? This article describes a switchable, multi-network tuner which is designed to optimize the matching possibilities available using commonly-available L/C components of moderate electrical and physical dimensions and, of course, of moderate cost. The tuner can be tailored to handle PEP output powers from 500 to 1000 Watts. The physical dimensions are quite moderate for the power-handling capabilities involved and one easily can add such features as selectable antenna switching and swr monitoring.

The schematic of the tuner is shown in Fig. 1. As shown, it incorporates selectable LC-, CL-, or T-network tuning, input switching direct to any of three loads (one of which can be a dummy load), switching using the tuner network to any one of two selectable antenna loads, and complete, internal swr measurement circuitry. Of course, one can scale up or down the possibilities shown in the schematic in any way desired in order to construct just the basic tuner, expand the antenna switching possibilities, etc.

The reason for having selectable LC- or CL-network tuning (a reversible L network) instead of a simple Pi-network option is to further increase the mileage obtainable out of the components used. Since two variable capacitors have to be used in the design of the tuner, the option is available to use them in a conventional Pi-network manner as tunable input/output capacitors or to parallel them and use them as combined output or input capacitors in a reversible L network. The latter will provide a greater range of impedance-matching possibilities at the expense of only a bit more component switching complexity, and so it was used.

If one uses a conventional input/output tuned Pi network with extremely wide-range variable capacitors, it usually will be found that any load that can be matched using both variable input/output capacitors can also be matched using only *either* a variable input *or* output capacitors and a suitable value of inductance. However, the capacitance range of a single variable capacitor required will usually be less than the combined capacitance of separate input/output variable capacitors in a Pi network.

The practical construction details of the tuner are not difficult to follow or perform if you approach them on a step-by-step basis. The 500-Watt output-rated version of the tuner is housed in an attractive two-tone blue/gray Radio Shack enclosure (#270-269) measuring 7-7/8" × 3-1/2" × 5-7/8". This aluminum housing is easy to work and you can construct the tuner using basic hand tools.

After you have initially sized-up the placement of components within the enclosure, drill or punch out the necessary mounting holes on the rear panel for the coax connectors, on the bottom of the enclosure for inductor and capacitor mounting, and on the front panel for control shafts, switches, meter, etc. Generally, the following sequence of mounting and wiring and components will make the tuner go together easily:

1) Mount the front-panel network changeover switch and the rear-panel coax connectors.

2) Mount the two variable capacitors. These capacitors have to be "above" ground. There are numerous ways to achieve a suitable mounting. The simplest is probably through the use of plastic #6 mounting screws/nuts with 1/4" spacers to keep the capacitor rotors above ground. If such material is not readily available, a 1/4"-thick piece of Plexiglas™ or bakelite can be used to raise the capacitors above the enclosure bottom using metal hardware.

3) Wire up the network changeover switch to the capacitors with leads extended to where the inductor and antenna selector switch will be mounted.

4) Mount the variable inductor and the swr measurement circuitry (if used).

5) Mount the antenna selector switch to the back panel (using 1/2" to 3/4" standoff hardware) and wire it up.

6) Mount the insulated shaft couplings on the variable capacitors, extension shaft to the antenna selector switch, etc.

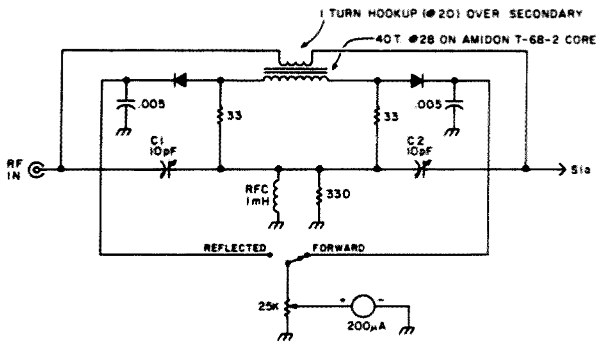

Fig. 2. The swr circuitry is simple but sensitive and needs no shielding inside the tuner enclosure. With a 50-Ohm carbon resistor on the S1 side and the meter switch to reflected, adjust C1 for minimum meter reading. Do the same with C2 when the resistor is connected to the rf in side and rf is fed into the S1a side of the circuit.

Of course, you can vary the location of the components in a variety of ways, but you should more or less plan out the construction of the tuner in the manner illustrated above. It really takes less time to complete than is involved in even assembling a commercial kit which often has rather laborious point-to-point wiring instructions.

Another swr bridge circuit was constructed using a toroid-core transformer and it worked very well. The circuitry of the bridge is shown in Fig. 2. The components are mounted on a small piece of perforated board stock; there is no need to etch a board for the few components involved and they can be wired together directly.

The board is mounted inside the rear panel of the tuner directly by the input coaxial connector. No shielding is required since the toroid is largely self-shielding. The sensitivity allows for measurements with 10 to 20 Watts of transmitter output power even on the low-frequency bands. The only thing that you must do, however, is to balance out the stray capacitances in the circuitry as noted in the caption for Fig. 2. The procedure is simple but it cannot be neglected if proper readings are to be obtained on 10 and 15 meters.

The meter used happened to be a surplus CB one that had an swr scale, but any inexpensive meter with a 200-mA or more sensitive movement will suffice. There is no real need to calibrate the meter since it normally is used only to adjust the tuner for a minimum reading in the reflected switch position once the meter has been adjusted for a full-scale reading in the forward switch position.

A minor point, by the way, about the meter switch used: It is spring-loaded, so it must be pushed down to read forward and will snap back to its reflected position (labeled SWR). This small refinement makes it rather easy to adjust the tuner since the way the switch and meter adjustment control are placed on the front panel the index finger on one hand can be used to depress the switch while the thumb and middle finger are used to adjust the control. The other hand is free

NOTE: Price, specifications subject to change without notice and obligation.

to adjust the tuning controls.

Speaking of controls, there is no turns indicator on the rotary inductor. Regular turns counters take up a lot of enclosure space and are not all that necessary unless you insist on extremely fast control presetting. In reality, if you note the setting of all the other controls for the band/antenna being used, it is a simple matter to rotate the inductor for approximate minimum swr and then finish up the tuning by going back and forth between the inductor and capacitor tuning controls.

It's no secret that it generally only makes sense to home-brew a tuner if one can find the components necessary at reasonable prices. If you built a 500-Watt version of this tuner using all new, off-the-shelf parts, the parts cost could easily run around $120. On the other hand, using surplus or new surplus parts, the cost could be as low as $25. Simply hunt around for the parts needed at the right prices. Fair Radio Sales (1016 E. Eureka, Box 1105, Lima OH 45802), for instance, which frequently advertises in *73*, often has very good buys on transmitting-type variable capacitors and inductors.

The tuner has been labeled as a "Universal Coupling Unit." That euphuistic name was only the result of having a limited selection of words available in a rub-on lettering set. No tuner will, of course, couple to absolutely all loads. The tuner described will couple a 50-Ohm output transmitter to just about any reasonable antenna load; the same as can be done by commercially available tuners which use the same type of circuitry and component dimensions. ■

Digital Basics

This is no time to be a digital illiterate. Part III reveals the secrets of multivibrators, shift registers, and other notorious devices.

Joseph J. Carr K4IPV
5440 South 8th Road
Arlington VA 22204

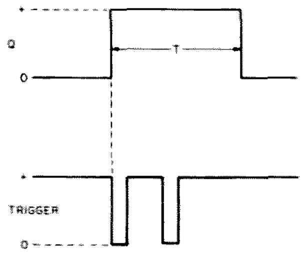

Fig. 1(a). One-shot multivibrator. Trigger pulse causes output to go HIGH for period T. The second pulse has no effect.

The first two parts of this three-part series led you step by step into the digital electronics swimming pool. We now can wade in past the ankle-deep water of the kiddies' pool and venture into knee-deep water. Thus far, we have discussed the various digital IC logic families, assorted types of gates, and a variety of flip-flops. We now will turn to the subjects of multivibrators and counters.

Multivibrators

A multivibrator is basically a pulse-producing circuit. There are three basic forms of multivibrator: *monostable, bistable,* and *astable*. It takes little imagination to detect that these designations refer to the *stable output states* that are possible for each type of circuit.

The monostable multivibrator has but *one stable state* (usually the state in which Q = LOW . . . but not always). Triggering the monostable multivibrator causes the Q to go HIGH for a time, but since this is not a stable state, Q will drop LOW again when a pre-determined time period has elapsed. Monostable multivibrators are also called *one-shot* circuits and also (erroneously, albeit graphically) *pulse-stretcher* circuits. The latter label is a misnomer because the circuit does not actually stretch a pulse but generates a *new* pulse that has a longer period.

The bistable multivibrator has two stable states. It can remain in either state (i.e., Q = LOW or Q = HIGH) indefinitely. The RS flip-flop is an example of a bistable multivibrator.

The astable multivibrator has *no* stable states. It is in-

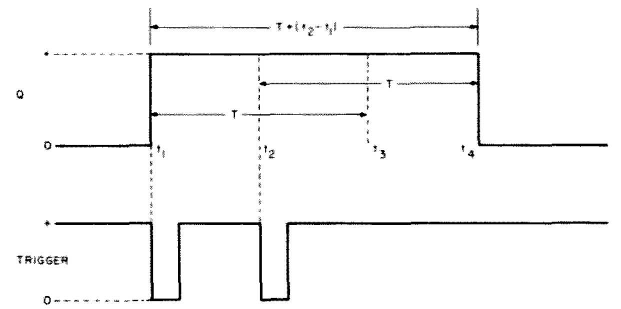

Fig. 1(b). A retriggerable monostable multivibrator can be retriggered while the output is still HIGH. Note that the total duration of the HIGH state is not 2T.

capable of remaining in either Q LOW or Q HIGH states. The Q output of the astable multivibrator will flip back and forth between the HIGH and LOW states, producing a square-wave pulse-train output signal. For this reason, the astable circuit is usually used to produce the clock pulses found in digital circuits.

There are several ways to produce each of these types of multivibrator. Space prevents us from considering all of them. We will examine a few circuits built from discrete gates and the integrated circuits. Some IC devices, like the 555 timer, will operate in either the monostable or astable mode.

When we speak of bistable multivibrators, we actually are talking about the RS flip-flop. Recall from the earlier sections of this article that the RS FF can remain happily in either the Q=LOW or the Q=HIGH states indefinitely.

Most monostable multivibrators will not respond to further input trigger pulses until the period of the output pulse has "timed out," i.e., the output has returned to its stable state. Monostables that will not respond to further trigger commands until the output duration has expired are *nonretriggerable* monostables.

Some one-shot circuits, however, are *retriggerable*, meaning that they will respond to further input trigger commands while the one-shot is in the unstable state (i.e., before it has timed out). Consider Fig. 1 to see how this works. Fig. 1(a) shows the operation of the regular nonretriggerable one-shot multivibrator. The first trigger pulse causes the output to go HIGH and it remains HIGH for period T. A second trigger pulse has no effect on the one-shot because it occurs before T expires.

Now consider Fig. 1(b). This is a timing diagram for the retriggerable monostable multivibrator. The output goes HIGH when the first pulse arrives. But before T expires, a second trigger pulse is received. This second pulse causes the one-shot to retrigger, so the output will remain HIGH for an additional period T. Note that the total duration of the HIGH state is not 2T, but T plus the portion of the first period that expired prior to the second trigger, or $T+(T_2-T_1)$.

An example of a monostable multivibrator built from a CMOS type-D flip-flop is shown in Fig. 2. Recall the rules for the type-D FF: (1) Since D is HIGH, a HIGH will be transferred to the Q output when the *CLK* line goes HIGH, and (2) when the *clear* line goes HIGH, the Q output is forced LOW. The operation of the one-shot circuit in Fig. 2, then, is as follows:

a) When the circuit is at rest, Q is LOW and any charge on capacitor C1 is drained off through diode D1.

b) When a trigger pulse is received by the *CLK* input, Q goes HIGH. When Q is HIGH, capacitor C1 will charge through resistor R1.

c) When C1 has charged to a potential of approximately 2 volts, the *clear* input thinks it is HIGH, so the FF will force Q LOW.

d) The period that Q was HIGH, i.e., the period of the one-shot, is determined by the time constant of R1C1 and the potentials of the Q output and the point at which the *clear* input thinks that it is HIGH instead of LOW.

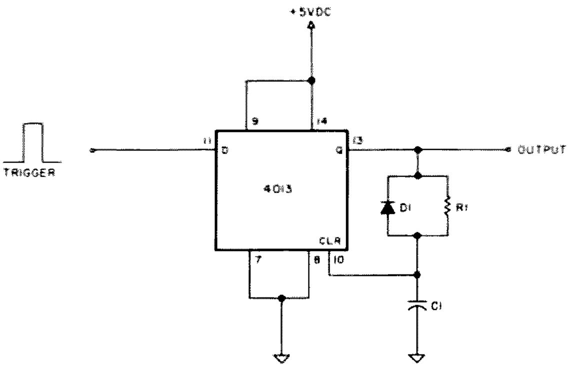

Fig. 2(a). A CMOS flip-flop is the basis for this monostable multivibrator. R1 and C1 determine the length of the pulse. D1 allows the flip-flop to be retriggered immediately after clearing.

The circuit in Fig. 2(a) uses a diode (D1) across the timing resistor (R1) to discharge C1 during the period when Q is LOW. This diode is not strictly necessary but serves to speed up the circuit considerably. Without D1, the charge on capacitor C1 would bleed off through R1. But this would require another R1C1 time constant (or so) before the voltage across C1 would discharge enough to permit retriggering of the one-shot. The purpose of D1 is to discharge C1 rapidly so that retriggering can occur almost immediately after Q drops LOW—see the waveform in Fig. 2(b).

The use of D1 creates a little problem, however.

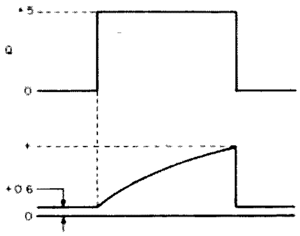

Fig. 2(b). The potential across C1 never drops below 0.6 volts because of the presence of D1.

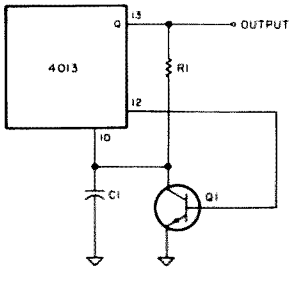

Fig. 3. Monostable multivibrator. The diode in Fig. 2(a) is eliminated by using Q1 to discharge C1.

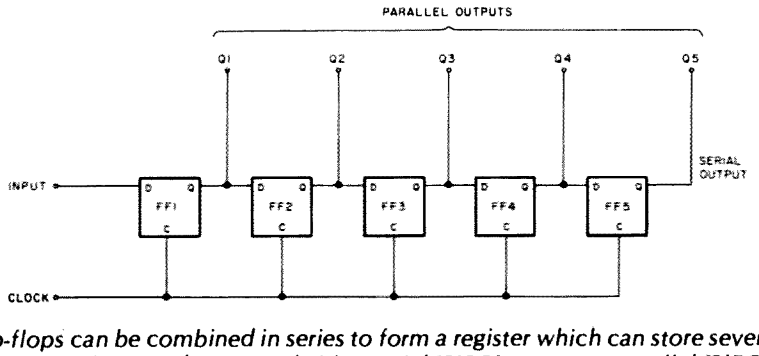

Fig. 4. Flip-flops can be combined in series to form a register which can store several bits of data. This version has serial input and either serial (SISO) output or parallel (SIPO) output.

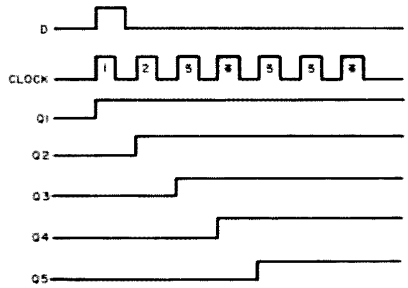

Fig. 5. The data bit (0) is transmitted through a five-stage SISO shift register by clocking the register five times.

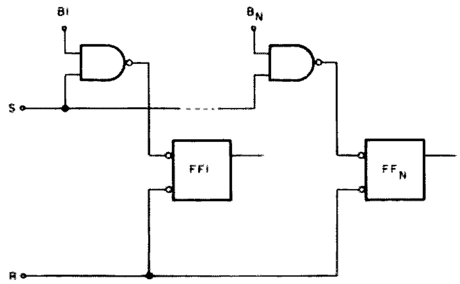

Fig. 6. Data is entered into this parallel-entry shift register via B1-B_n. Before entry, the register is reset via R. The data is then loaded by bringing the set line (S) HIGH.

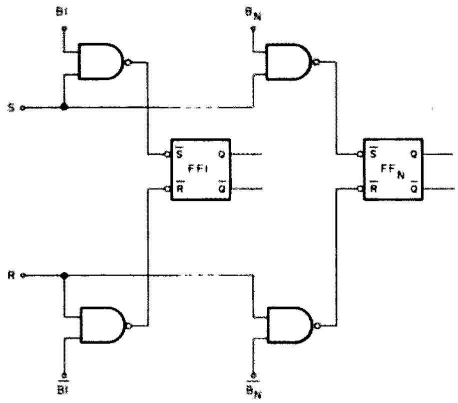

Fig. 7. The jam parallel-input shift register eliminates the need to clear the registers.

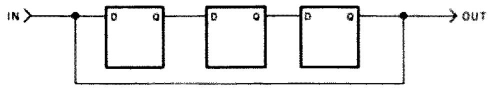

Fig. 8. A recirculating shift register automatically couples the output data back to the input. This is something like a dog chasing its tail.

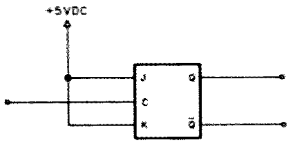

Fig. 9(a). The core of most frequency counters is the J-K flip-flop configuration. In this case, the J and K inputs are both tied HIGH.

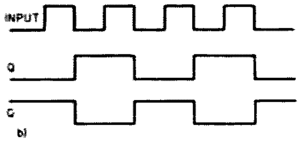

Fig. 9(b). A single J-K flip-flop is a divide-by-two counter.

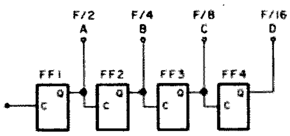

Fig. 10(a). By cascading several J-K flip-flops, the division ratio increases by powers of two.

The charge potential across C1 cannot drop lower than the function potential of the diode (200 to 300 millivolts in germanium types and 600 to 700 millivolts for silicon types). Fig. 3 shows the circuit for a modified version that uses switching transistor Q1 to discharge C1. The base of transistor Q1 is driven by the NOT-Q output of the 4013 flip-flop.

Shift Registers

A flip-flop is able to store a single bit of digital data. When two or more flip-flops are organized to store multiple bits of data, then they constitute a *register*. Most registers are merely specially-connected arrays of flip-flops.

There are several different circuit configurations that one would call a register, and we classify them according to the manner in which data is input and output to and from them. We have, for example, *serial-in-serial-out* (SISO), *serial-in-parallel-out* (SIPO), *parallel-in-parallel-out* (PIPO), and *parallel-in-serial-out* (PISO).

Fig. 4 represents both SISO and SIPO shift registers. The only significant difference is that the parallel output lines, used on the SIPO register, would be absent on the SISO register.

The SIPO shift register consists of a cascade chain of type-D flip-flops that have their clock lines connected together. Recall the rules for type-D flip-flops: Data can be transferred from the D input to the Q output only when the clock input is HIGH. The input can change at will and the output will remain the same as long as the clock line is LOW. But if the clock line goes HIGH, the Q output will follow the D input. The Q output will retain the last valid data present before the clock dropped LOW again.

This rule can be applied to the situation shown in Fig. 5, where we show the transmission of a single bit of data from left to right through a SISO shift register. At the occurrence of the first clock pulse, the input line is HIGH. This point is the D input of FF1, so a HIGH, which is applied to the D input of the second flip-flop (FF2), remains after the clock pulse disappears.

When the second clock pulse arrives, FF2 sees a HIGH on its D input and FF1 sees a LOW on its D input. This situation causes a LOW at Q1 and a HIGH at Q2.

The third clock pulse sees a LOW condition on the D inputs of FF1 and FF2 and a HIGH at the input of FF3. The third clock pulse, then, causes Q1 and Q2 to be LOW and Q3 to be HIGH.

Note that the SISO input remains LOW after the initial HIGH during clock pulse number 1. This means that the single HIGH condition will be propagated through the entire SISO shift register, one stage at a time. The HIGH bit will shift one flip-flop to the right each time a clock pulse arrives.

If the data at the input had changed, then the bit pattern at that input would be propagated through the shift register.

The shift register in Fig. 4 is a five-bit, or five-stage, register (any bit length could be selected). On the sixth clock pulse, therefore, the HIGH is propagated out of the register, so all flip-flops are now LOW.

The SISO shift register can be made into a SIPO device by adding parallel output lines at Q1, Q2, Q3, Q4, and Q5.

One use for the SIPO register is serial-to-parallel binary-code conversion. For economic reasons, digital data usually is transmitted as a serial stream of bits, i.e., the bits of the digital word are sent over a communications link. But most computers and other digital instruments use a parallel form of data entry. Parallel data transfer is more expensive but is considerably faster than serial transmission. If, for example, we have an eight-bit system, we would need an eight-stage SIPO shift register to convert the serial code to parallel form. The code is entered into the SIPO register one bit at a time so that after eight clock pulses the first bit will appear at Q8 and the last bit at Q1.

Parallel-entry shift registers are faster to load than serial-input shift registers. This is because a single bit can be changed, if needed. In the serial type, to change a single bit of data requires us to ripple through the entire contents.

There are two basic forms of parallel data entry: *parallel* and *jam*. In parallel entry, shown in the partial schematic of Fig. 6, the register must first be cleared (i.e., all bits set to zero) by bringing the *reset* line momentarily LOW. The data that is applied to inputs B1 through B_n can be loaded into the register by momentarily bringing the *set* line HIGH.

The jam entry circuit shown in the partial schematic of Fig. 7, is also able to load data from bits B1 through B_n. While jam entry may not look superior at first glance, it is, because IC shift registers using this technique have internal inverter stages at the complement inputs. These have their inputs connected to

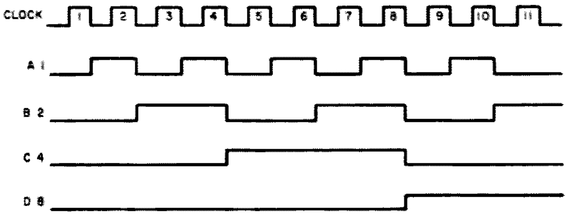

Fig. 10(b). A modulo-16 ripple counter has four outputs.

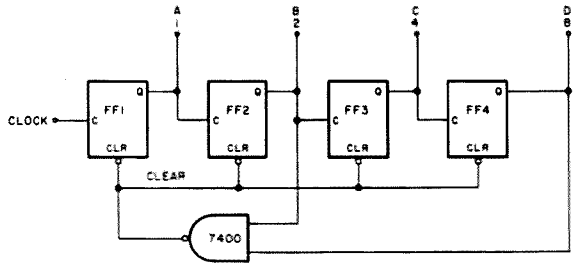

Fig. 11(a). A counter can have something other than a divide-by-two ratio when the flip-flops are forced to reset. The 7400 turns a divide-by-sixteen counter into a divide-by-ten circuit.

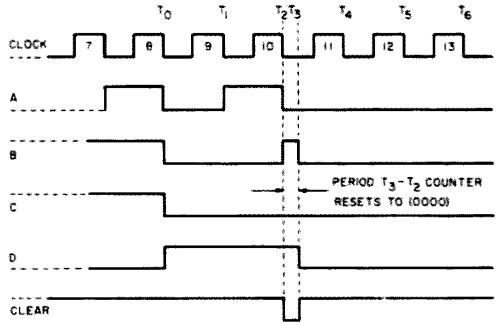

Fig. 11(b). After ten pulses, the counter resets. The result is a decimal-based counter.

the non-complemented inputs, eliminating the need to clear the register before loading.

A recirculating shift register is shown in Fig. 8. Since the output of a serial shift register allows the outside world to see only one bit at a time, we must empty the entire contents of the shift register in order to read these contents. But that would ordinarily destroy the data, because the input would be HIGH or LOW during the entire operation. A single-read operation, then, would fill up the register with all ones or zeros. The recirculating shift register connects the output (serial output) back to the input, so that a read operation would automatically rewrite the data back into the shift register.

Digital Counters

A *digital counter* is a device or circuit that operates as a *frequency divider*. The most basic digital counter is the J-K flip-flop connected with the *J* and *K* inputs tied HIGH (i.e., placed in the clocked mode). This makes the output produce one output pulse for every two input pulses. It is, then, a binary or divide-by-two counter.

Those fancy digital frequency/period counters are nothing more than digital divide-by-10 counters connected so that the binary-coded output is converted to a decimal display.

There are two basic classes of digital counter circuits, serial and parallel. The serial counters are called ripple counters because a change in the input must ripple through all stages of the counter to its proper point. Parallel counters also are called synchronous counters.

In a ripple counter, the data is transferred serially, which means that the output of one stage becomes the input of the next stage.

The basic element in most counters is the J-K flip-flop. See Fig. 9(a). Note in the figure that the *J* and *K* inputs are permanently tied HIGH, so they will remain active.

A timing diagram for this divide-by-two circuit is shown in Fig. 9(b), and it shows the action of the circuit. J-K FF outputs change state on negative-going transitions of the clock pulse. In Fig. 9(b), the first negative-going transition causes the Q output to go HIGH. Q will remain HIGH until the input sees another negative-going clock pulse. At that time, the output will drop LOW. The action required to make a complete output requires two clock pulses, so this J-K flip-flop is dividing the input frequency by two.

We can make a binary ripple counter by cascading two or more stages, as shown in Fig. 10(a). This particular circuit uses four J-K FFs in cascade. Any number, however, could be used.

The major problem with this type of counter is that only those division ratios that are powers of two can be accommodated. In the four-stage circuit shown, the possible division ratios are 2, 4, 8, and 16.

Frequency division is one major use for a counter circuit. In some electronic instruments, for example, we may want to prescale a fre-

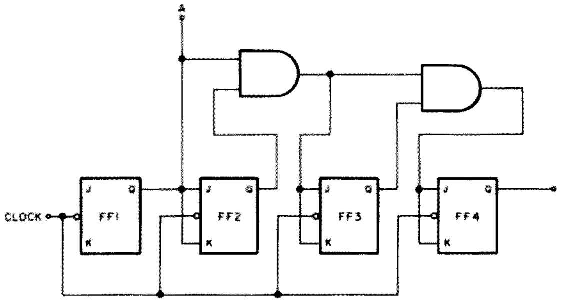

Fig. 12. By feeding the clock inputs in parallel, a synchronous counter becomes much faster than the ripple version.

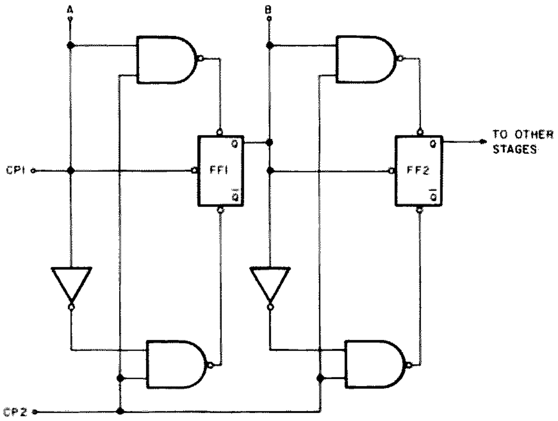

Fig. 13. A preset counter can be made by using a jam input. When CP2 is raised HIGH, a preset bit pattern is entered.

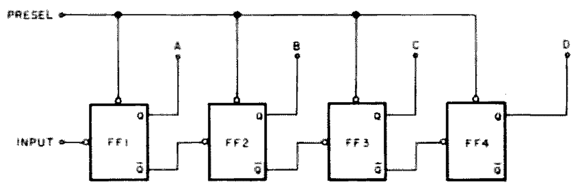

Fig. 14(a). A counter can count down by toggling each flip-flop with the preceding stage's $\overline{Q}$ output.

quency, i.e., divide it from some other frequency to a lower frequency that can be handled by a digital counter or other digital instrument.

But this is only one application for the counter circuit. One of the most common applications, alluded to in the last paragraph, is to *count*, i.e., tell us the total number of pulses that passed. Consider again the circuit of Fig. 10(a) and the timing diagram of Fig. 10(b). Outputs A, B, C, and D are coded in binary, with A being the least significant bit and D the most significant. These are weighted in a 1-2-4-8 code system to represent decimal digits 0 to 9 or hexadecimal digits 0 to 15. These are the normal weights of the binary number system.

Consider the timing diagram of Fig. 10(b). Note that all B output changes occur following the arrival of a pulse. After pulse number one has passed, the Q_A line is HIGH and all others are LOW. This means that the binary word on the output lines is 0001_2 (i.e., 1_{10}); one pulse has passed.

Following pulse number 2 we would expect 0010_2 (i.e., 2_{10}) because two pulses have passed. Note that Q_B is HIGH and all others are LOW. The digital word is, indeed, 0010_2.

The counter in Fig. 10(a) is called a *modulo-16*, or *base-16*, counter, or a hexadecimal counter (all meaning the same thing). The output of a *hexadecimal* counter can be decoded to drive a display device that indicates 0 through 9 (i.e., decimal) or 0 through F (hexadecimal). In most applications where a real, live, human is to read the display, a *decimal* readout is provided.

Decimal Counters. A decimal counter operates in the *base-10*, or *decimal*, number system. The most significant bit of a decimal counter produces one output pulse for every ten input pulses. Decimal counters are also sometimes called *decade counters*. The decimal counter forms the basis for digital *event*, *period*, and *frequency* counters. Thus, the hexadecimal counter in Fig. 10 is not suitable for decimal counting unless it is modified for base-10 operation.

Fig. 11 shows a TTL hex counter modified by adding a single TTL NAND gate. Recall that a TTL J-K FF uses inverted inputs for the clear and set functions. As long as the clear input remains HIGH, the flip-flop will function normally, but when the clear input is momentarily brought LOW, then the Q output of the FF goes LOW.

The decade counter in Fig. 11(a) is connected so that all four clear inputs are tied together to form a common clear line. This line is connected to the output of a TTL NAND gate (i.e., one section of a 7400 device). Recall the rules of operation for the TTL NAND gate: If either input goes LOW, then the output goes HIGH, but if both inputs are HIGH, then the output goes LOW.

The idea behind the circuit of Fig. 11 is to clear the counter to 0000 following the tenth input pulse. Let's examine the timing diagram in Fig. 11(b) to see if the circuit does the correct thing. Up until the 10th pulse, this diagram is the same as for the base-16 counter discussed previously.

The output of the NAND gate will keep the clear line HIGH for all counts through 10. The inputs of this gate are connected to the B and D lines. The D line stays LOW, forcing clear HIGH up until the 8th input pulse has passed. At that time—T_0 in Fig. 11(b)—D will go HIGH and bit B drops LOW, so the clear line remains HIGH for the 9th pulse.

The clear line will remain HIGH until the end of the 10th pulse. At that point (T_2) both B and D are HIGH, so the NAND gate output drops LOW, clearing all four flip-flops (i.e., forcing them to the state where all four Q outputs are LOW). The counter is therefore reset to 0000.

The reset counter produces a 0000 code, so the B and D outputs are now LOW, forcing the clear line HIGH again. The entire reset cycle occurs during period $T_1 - T_2$). This period has been expanded greatly for graphic illustration purposes in the figure, but actually takes only nanoseconds or microseconds.

The 11th pulse will increment the counter one time, so the output will be 0001_2. The count sequence, in decimal, then, is 0-1-2-3-4-5-6-7-8-9-0-1 . . . etc. The output code is a ten-digit version of four-bit binary (hexadecimal) and is called *binary-coded decimal*, or BCD.

Synchronous Counters. Ripple counters suffer from one major problem: *slow speed*. The counter elements are wired in cascade, so an input pulse must ripple through the entire chain before it affects the output.

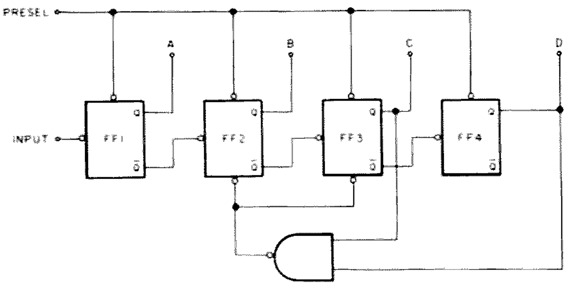

Fig. 14(b). This decade counter counts down, starting at the binary state 1001.

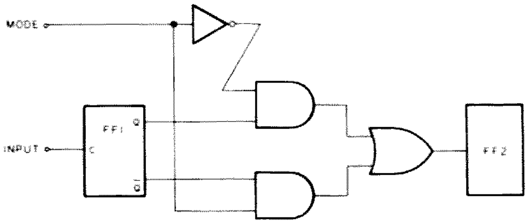

Fig. 15. A counter can offer the choice of up and down modes by adding logic.

A synchronous counter feeds the clock input to all flip-flops in parallel, and this results in a much faster operation.

Fig. 12 shows a partial schematic for a *synchronous binary counter*. We accomplish synchronous operation by using four flip-flops, with clock inputs tied together, and a pair of AND gates.

One AND gate is connected so that both Q1 and Q2 are HIGH before FF3 is active. Similarly, Q2 and Q3 must be HIGH before FF4 is made active. On a clock pulse, any of the four flip-flops scheduled to change will do so simultaneously. Synchronous counters attain faster speeds, although ripple counters seem to predominate in most applications.

Preset Counters. A preset counter increments from a preset point other than 0000. For example, suppose we wanted to count from 5_{10} (0101_2). We could preset the counter to 0101 and then increment from there.

Fig. 13 shows a common method for achieving preset conditions for the *jam* input. Only two stages are shown here, but adding two additional stages will make it a four-bit counter. Of course, any number of stages may be connected in cascade to form an *n* but preset counter.

In Fig. 13, the preset count is applied to points A and B, and both bits will be entered simultaneously when clock line CP2 is brought HIGH. Line CP2 is sometimes called the enter or jam terminal. Once the preset bit pattern is entered, the counter will increment from this with every transition of clock line CP1.

Down Counters. A down counter decrements, instead of incrementing, the count for each excursion of the input pulse. If the reset condition is 0000, then the next count would be 0000 −1, or 1111 (it would have been 0001 in an up counter).

We use basically the same circuit as before but toggle each FF from the NOT-Q rather than Q of the preceding FF. An example of a four-bit binary down counter is shown in Fig. 14. Note that the outputs are taken from the Q outputs of the FFs but that toggling is from the NOT-Q.

The preset inputs of the flip-flops are connected together to provide a means to preset the counter to its initial (i.e., 1111) state. This counter is also called a *subtraction counter* because each input pulse causes the output to decrement by one bit.

A decade version of this circuit is shown in Fig. 14(b). As in the case of the regular decade counter, a NAND gate is added to the circuit to reset the counter following the 10th count. We detect the states where outputs C and D are HIGH, and then clear the two middle FFs. This action forces the output to 1001_2 (i.e., 9_{10}). The counter then decrements from 1001 in the decimal sequence 9-8-7-6-5-4-3-2-1-0-9 etc.

Up/Down counters. Some counters will operate in both up and down modes, depending upon the logic level applied to a *mode* input. Fig. 15 shows a representative circuit in which the first two stages of a cascade counter are modified by the addition of several gates. If the mode input is HIGH, then the circuit is an up counter, but if the mode input is LOW, then the circuit operates as a down counter.

Conclusion

This three-part series has offered you the basics of digital electronics. With this information, you should be able to conduct a large number of experiments, build most of the simple-to-moderate-difficulty digital projects published in this (and other) magazines, and even design a few circuits. From here, let me recommend that you begin to study microprocessors and microcomputers. From the radio amateur's point of view, interfacing is very important. ■

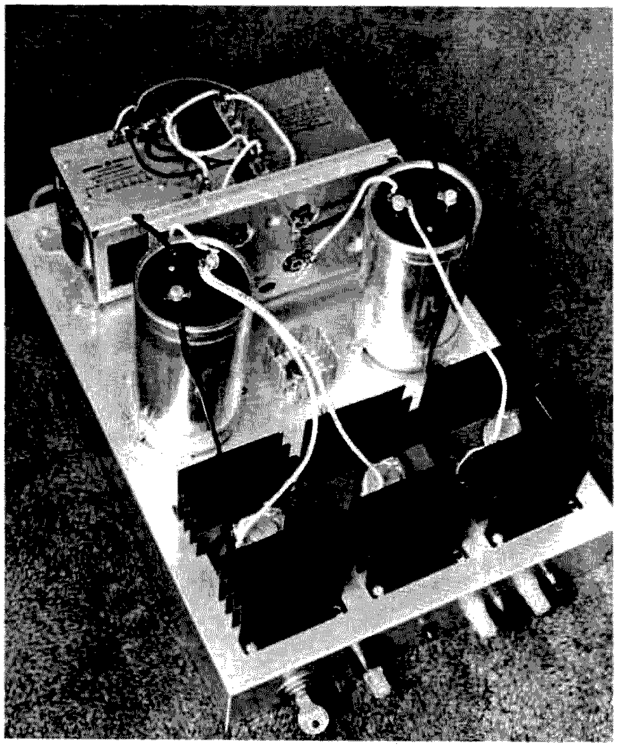
The Money-Maker Power Supply

Need 12 volts for your transceiver? Save half the cost of a commercial unit by assembling this 25-Amp monster.

Since the advent of solid-state transceivers, there has been the need for a simple high-current 12-volt power supply. The power supply described in this article will produce 13.8 volts at up to 25 Amps continuous duty. All the parts should be readily available.

First of all, you will need to determine how much current your transceiver draws, and at what voltage. Look up the current drain during transmit in your owner's manual. For a 100-Watt radio, this may be about 20 Amps. Most transceivers, whether they be small two-meter radios or large multiband 100-Watt HF ones, will have a voltage rating of 13.8 volts. This seems to be an industry standard. Thus, if you were to build a 12-volt supply, you probably would not achieve the full rated power output.



The completed 13.8-volt, 25-Amp supply includes overvoltage protection.

Once the voltage and maximum current are determined, you may choose a transformer. If it is not possible to find one of the proper ratings locally, then try requesting catalogs from the following three companies. They all seem to have a large stock of transformers at good prices.

A minimum of 13.3 volts rms must be supplied to the filter for a regulated output of 13.8 volts. This is equal to the desired output voltage plus five volts divided by 1.414. The current rating, of course, must be greater than or equal to the desired output current. In my case, the required current was 22 Amps at 13.8 volts. Thus, the transformer should have a current rating of at least 22 Amps and the secondary rms voltage should be *at least* 13.3 volts (13.8 + 5)/1.414. I chose, from the Meshna catalog, a 15-volt, 15-Amp autotransformer. The stock number was T-658 and the price was eight dollars. I bought two of them to put in parallel for a total of 30 Amps. Meshna provides instructions to convert these autotransformers to regular transformers. This just involves rewiring of the attached terminal board.

While you are looking through the catalogs, keep an eye out for some high-current rectifiers, large heat sinks for both the rectifiers and the pass transistors, and some "computer-

grade" capacitors. See the parts list for the values. Also, please note that in most cases, the values in this power supply are not very critical. As long as they are close, they should work. Most of the smaller parts are available at Radio Shack. In these cases, the part numbers are shown as RS numbers.

Circuit Description

The circuit is a full-wave bridge rectifier with a linear regulator. See Fig. 1. The voltage regulator consists of an LM317 which provides base drive for the pass transistors. The LM317 is an adjustable three-terminal voltage regulator that when supplied with 27 volts on its input can provide an adjustable 1.2-to-25 volts at 1.5 Amps. In this case, we will be inputting 15 volts times 1.414 or 21.2 volts (peak) from the rectifier/filter combination. The regulator output voltage must be 13.8 volts plus the base-emitter drop of the pass transistors. This will be 13.8 volts + 0.7 volts, or 14.5 volts.

Three pass transistors are used and they share the output current equally. There are several options for overvoltage protection and these will be discussed towards the end.

Circuit Blocks

Each section in the block diagram will now be described. When doing the actual construction, build one block at a time and test it as you go. This will save debugging time and may prevent burned out parts. Build them in this order:

1) Power transformer, rectifiers, filter capacitors, and 117-V ac input circuit.

2) Voltage-regulator circuit (LM317).

3) Pass-transistor circuit.

4) Output-protection circuit.

Note that the power supply can be used without any protection circuit, but you must be very careful of short circuits. It is possible to lose the supply *and* the radio with one mistake!

Transformer Circuit

The transformer circuit consists of the line cord, fuse, pilot lamp, transformer, rectifiers, and filter capacitor. See Fig. 2. Get yourself a heavy-duty line cord for this power supply as you may be drawing 3 to 4 Amps on the transformer primary. A three-wire cord is preferred and the green or ground wire should be connected to the power supply chassis.

Use a 5- to 10-Amp fuse for the primary circuit and a small neon lamp with built-in series resistor for the pilot lamp. I used a key lock for the On-Off switch to prevent "unauthorized" use.

First, mount and wire the transformer(s) and line cord to the chassis. Connect the switch, pilot lamp, and fuse to the primary circuit. Then mount the rectifiers to the rectifier heat sink and mount the assembly near the secondary side of the transformer. Use at least number 12 or, better, number 10 house wiring to wire all the secondary circuits, rectifiers, and pass transistors. The rectifiers must have mica insulators so they won't short out through the heat sink. Also, a layer of silicone thermal grease should be applied between the rectifiers and the heat sink. Extra grease should be wiped off after the rectifiers are bolted down. The rectifiers will have a voltage drop of about one volt at 25 Amps, so the power they must dissipate will be: 1 volt times 25 Amps at a 50% duty cycle = 12.5 Watts each. Make sure the heat sink is a large one.

Next, mount the filter capacitor(s). Use heavy gauge wire for the capacitor(s), too. Now, recheck all wiring

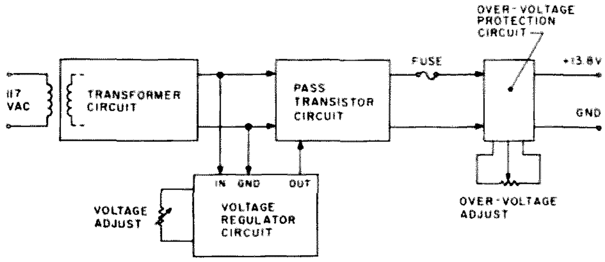

Fig. 1. Block diagram of the complete power supply. Each section is discussed separately. There are three options for the overvoltage protection circuit.

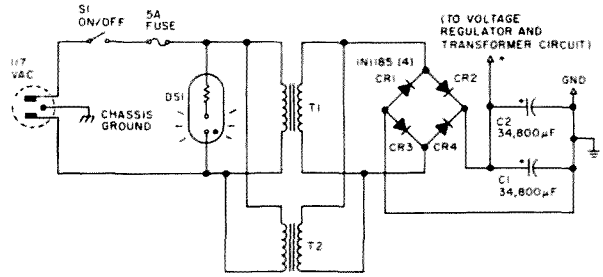

Fig. 2. Schematic diagram of the transformer section. The transformers are rated 15 volts at 15 Amps.

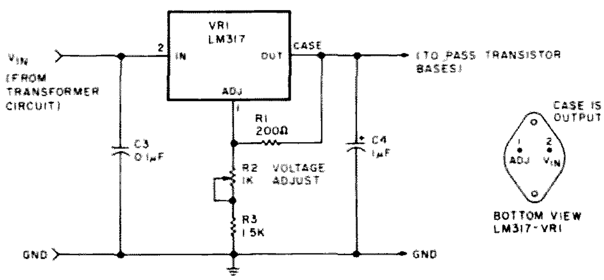

Fig. 3. Schematic diagram of the voltage regulator. R1 can be 200 to 250 Ohms. All resistors are rated at 1/2 Watt. C3 is a ceramic and C4 is electrolytic. Both should be mounted as close to VR1 as possible.

against the schematic. Make sure that the switch is off and plug the line cord into the wall socket. Be careful of any primary transformer connections as there will be 117 V ac there. Connect a voltmeter set on the 50-volt scale to the filter capacitor terminals and turn the power on. You should measure an unloaded voltage of about 15 volts times 1.414 = 21.2 volts dc. Record your voltage reading, as we will be using it for some power calculations later. Make sure the On-Off switch works and that the pilot light works with the switch. Note that since there is nothing connected to the filter capacitor terminals to bleed off the voltage stored there, it might be wise to connect a 1000-Ohm, 1/2-Watt resistor across the terminals before continuing. Turn the power off and use your voltmeter to verify that the voltage is near zero.

Voltage Regulator Circuit

Now start construction of the voltage-regulator circuit. See Fig. 3. Mount the LM317 regulator to the chassis using a small TO-3 heat sink. Use some silicone

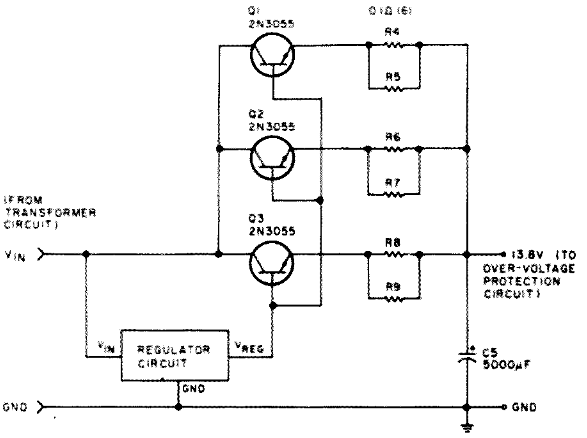

Fig. 4. Schematic diagram of the pass transistor section.

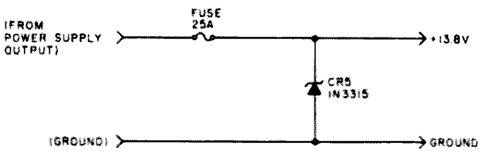

Fig. 5. Option 1 overvoltage protection circuit.

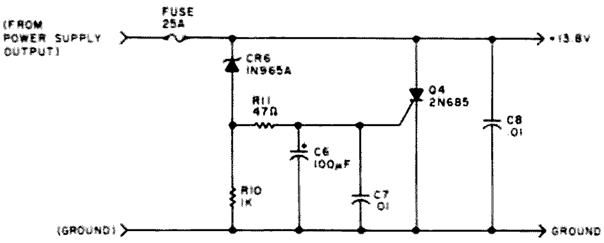

Fig. 6. Option 2 overvoltage protection circuit.

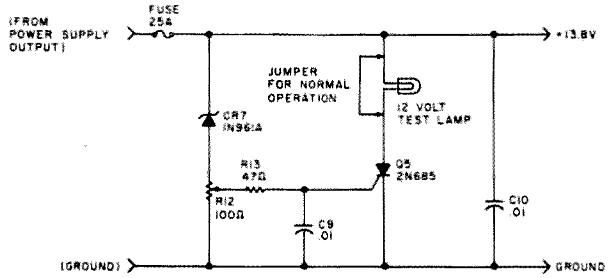

Fig. 7. Option 3 overvoltage protection circuit. This version has an adjustable voltage-limit point.

grease and be sure to use a mica insulator because the regulated output voltage is connected to the case. To determine the power dissipation of this regulator, take the unloaded voltage reading you took earlier and subtract 14.5 volts. Then multiply by 1.5 Amps. In my case, the power dissipated was: (21.2 volts minus 14.5 volts) times 1.5 Amps = 10 Watts. The heat sink must be large enough to dissipate this power.

Mount the voltage control pot on the top or the front of the chassis. Finish wiring the regulator circuit using point-to-point methods. Here, you can use smaller gauge wire since the highest current will only be 1.5 Amps. Now connect the regulator input to the positive terminal of the filter capacitor. Make sure that the negative terminal of the filter capacitor is grounded to the chassis.

Temporarily connect a 10- to 50-Ohm, 10-Watt resistor across the voltage regulator output to act as a load. Connect a voltmeter across this load resistor and set the voltage control to the midway point. Turn on the power and verify that you are getting about 11 to 17 volts as the voltage-control pot is adjusted. If the output does not vary with the control, double-check the wiring to the LM317.

Pass Transistor Circuit

If everything is OK so far, the next step is to mount the pass transistors. See Fig. 4. Use large TO-3 heat sinks and mount the transistors using mica insulators and silicone grease. Be sure to drill holes in the chassis for the wires to the transistors. Use rubber grommets.

To determine the maximum power dissipation of the pass transistors, you will need the unloaded voltage you measured across the filter capacitor. Take this voltage and subtract 13.8 volts. Then multiply this by one third of the total output current. In my case, the power dissipated in each transistor was (21.2 volts minus 13.8 volts) times (22 Amps/3) = 54.3 Watts. Make sure that the heat sinks are large enough to dissipate this much heat. I found that a finned heat sink of about 3" times 4" times 2" was alright.

After the transistors are mounted to the chassis, connect all the bases together and run a wire from there to the voltage-regulator output. Small gauge wire is OK. Connect two 0.1-Ohm, 5-Watt resistors in parallel and solder one end of this to one of the emitters. Connect the other four resistors likewise. Finish the rest of the pass-transistor sections using 10- or 12-gauge wire for the emitter and collector terminals, the connections to the filter capacitors, and to the output terminals of the power supply.

Verify all wiring completed so far and then connect a 1- or 2-Ohm, 200-Watt resistor across the power supply output (you'll probably have to combine several resistors to get one of these). Connect a voltmeter across this load resistor. Turn the voltage control to minimum. Stand back and turn the power on! If all goes well, you should see a voltage of about 10 volts. If you are using a load resistor of 1 Ohm, then it is drawing 10 volts/1 Ohm = 10 Amps. Try adjusting the voltage control and record the minimum and maximum voltages. These limits should bracket the required 13.8 volts. Make sure that the maximum power supply voltage will not exceed the trip-point of the overvoltage protection circuit. Otherwise, it will trip and you will lose a fuse. If you choose not to install a protection circuit, you may lose a radio!

Output-Protection Circuit

It is surprising how many commercial power supplies, including those of various ham manufacturers, do not incorporate some form of overvoltage circuit. The following are three options that will work. All use some method of sensing an overvoltage condition and then clamping or "shorting" the power supply output, thus blowing a high-current fuse.

The first and simplest option is to use a zener diode directly across the output. See Fig. 5. Choose a zener voltage of about two volts over the normal power supply voltage. The current rating should be greater than that of the power supply so

the fuse, rather than the zener, will blow. The current rating of the fuse should be between the power supply output current and the zener current rating. For example, for this power supply, choose a 25-Amp fuse and a 16- or 17-volt, 50-Watt zener.

The disadvantage of this circuit is that it is not adjustable and there still may be a chance that the zener will blow first before the fuse. This will still protect your radio, because when zeners fail, they usually stay shorted and this will reduce the overvoltage to near zero.

The second option is also not adjustable. It is an SCR (silicon-controlled rectifier) crowbar circuit. This circuit was published by Tom Lawrence WB4QLW in *73 Magazine,* August, 1977. This is the one I used for my power supply because it is fairly simple and the parts are readily available. See Fig. 6.

Here is how it works: As the power supply output starts to increase from normal and reaches the zener voltage, the zener will start to conduct current. This current will produce a voltage drop across the 1000-Ohm resistor and trigger the gate of the SCR. When the SCR becomes triggered, it will latch on and short the power-supply output, thus blowing the fuse. It is really not necessary to heat-sink the SCR since the shorted condition will last only as long as it takes for the fuse to open. Make sure that the maximum adjustable output voltage is less than the zener voltage rating.

The third and last option is similar to the previous except that the crowbar voltage is adjustable. See Fig. 7. This circuit was published by Joel Eschmann K9MLD in *73 Magazine,* August, 1979.

The operation is the same, except the trip-point can be adjusted from the zener voltage rating upwards. To test this circuit, break the connection between the anode of the SCR and the positive output line. Insert a 12-volt lamp in series as shown. Adjust the voltage control for maximum voltage and adjust the overvoltage control to maximum (wiper all the way toward the ground end).

Turn on the power supply. The test lamp should be off. Start turning the overvoltage control until the lamp just turns on. Now turn the control about 1/8 to 1/4 turn back in the other direction. This will add a small buffer zone. The lamp should still be on. Now turn the power supply off and then on again. The lamp should stay off. If the lamp is still on, try the adjustment again.

Try turning the voltage-adjust control from maximum to minimum and then back to maximum. The lamp should remain off. If so, all is well. Note that to turn off the lamp it is necessary to reset the SCR by momentarily turning off the power supply. When the crowbar is adjusted correctly, remove the lamp and reconnect the anode of the SCR back to the positive output. Now, when the overvoltage reaches the trip-point, the SCR will turn on and blow the fuse.

Parts List

Item	Qty.	Item	Buy at	Approximate Cost
C1, C2	2	34,800 μF, 50 V ea., or equiv.	Meshna	$ 5.00
C3	1	0.1 μF	RS272-0135	$ .39
C4	1	1 μF	RS272-1055	$ .89
C5	1	4700 μF, 25 V	RS272-1022	$ 3.59
CR1-4	4	1N1185, 150 V, 35 Amp	Meshna	$ 4.50
DS1	1	Neon lamp w/series resistor	RS272-0706	$ 2.19
Q1-Q3	3	2N3055 or equivalent	RS276-2020	$ 5.97
R1	1	200 to 240 Ohms, 2 W	RS271-0135	$ .89
R2	1	1000-Ohm potentiometer	Meshna	$ 1.00
R3	1	1.5k, 1/2 W	RS271-0025	$ .19
R4-R9	6	0.1-Ohm, 3 W, or equivalent	Meshna	$ 1.00
S1	1	SPST switch, 5 A contacts	RS275-0603	$ 1.49
T1, T2	2	15 V, 15 A transformer or equivalent	Meshna	$16.00
		Option 1 Parts		
CR5	1	16 V or 17 V, 50 W zener (1N3315)		
		Option 2 Parts		
C6	1	100 μF, 35 V	RS272-1016	$ 0.79
C7, C8	2	0.01 μF	RS272-0131	$ 0.29
CR6	1	15 V, 400 mW zener (1N965A)		
O4	1	50-100 V, 16 A SCR (2N685, 2N1844, 2N4441)		
R10	1	1000 Ohms, 1/2 W	RS271-0023	$ 0.19
R11	1	47 Ohms, 1/2 W	RS271-0009	$ 0.19
		Option 3 Parts		
C9, C10	2	0.01 μF	RS272-0131	$ 0.29
CR7	1	10 V, 400 mW zener (1N061A)		
Q5	1	50-100 V, 16 A SCR (2N685, 2N1844, 2N4441)		
R12	1	100-Ohm potentiometer		
R13	1	47 Ohms, 1/2 W	RS271-0009	$ 0.19

Conclusion

This completes the construction of the basic power supply. If you wish, you may add a voltmeter and an ammeter. You also may wish to make and install a cover to dress up the chassis.

The voltage adjust and overvoltage-protection adjust controls may be placed anywhere out of the way. If you plan to use this supply in a dedicated application, the controls, once set, may be left alone.

If you will be using the supply at various voltage levels, I would suggest option 1 or 2 for your protection circuit. That way, there will be less chance to misadjust the overvoltage control and, consequently, less chance of blown fuses.

So, enjoy your new power supply and, at the same time, observe normal precautions while using its high-current capabilities. Also, if you have a well-stocked junk supply, just think how much you will have saved over a commercial supply! If you have any questions, please send an SASE for a reply. Have fun! ■

TVRO Q & A: Part III

LNAs are expensive, but rolling your own is a losing proposition.

Ken Rae WBØPOP
737 South Clarkson
Denver CO 80906

What is the purpose of an LNA?

The purpose of an LNA is to amplify the signal collected by the feedhorn (approximately 4 microvolts) to a usable level without adding any appreciable noise.

Are all 120-degree LNAs the same?

No, they are not. Some manufacturers meet the specifications by just a bare margin, and other manufacturers give you a 100-degree LNA yet call it a 120-degree LNA because it's sort of a stepping stone; you buy either a 100 or 120. There are some indications that manufacturers will include a 105-degree LNA as a step in progression of degrees Kelvin.

Is the LNA's bandwidth important?

A few years back it was said that the bandwidth of many LNAs was too wide for TVRO application. Since then most of the manufacturers have installed bandpass filtering to narrow down the amount of outside noise that could come in. We don't want the whole world walking through the LNA. We would like to amplify the TVRO frequencies exclusively.

Should I buy or build an LNA?

I recommend that you buy your first LNA. I've seen only 10% of the people who try to construct an LNA actually succeed and build something that is worth having. The disasters are horrible, so if you build an LNA, do it after you have bought one. Buy one, put your system up, get it running, and then go back and construct a low-noise amplifier for your own use and education. Then you can sell your commercial LNA for the same price you paid for it.

How hard is it to build an LNA?

An analogy would be if you went down and got plate-glass sheets and tried to grind your own zoom lens for a 35mm camera. You can just imagine the precision required to do this and to add optical coating that you would have to put on for color pictures. Well, you're trying about the same thing when building an LNA.

What is the most misunderstood thing about building an LNA?

That it is much like HF work or the old tube work clear back into the fifties, where you could simply insert a tube or transistor and turn the machine on to see it run. GaAsFETs have a very critical LC reactive component to their nature, and if these parameters are not met the transistor will not perform. Meeting these parameters is difficult and takes a lot of time and meticulous work. There are people who claim that they can throw transistors into a stripline design and learn the recipe for creating a low-noise amplifier. In some cases this does work. But as a general rule, the misconception is that you can put it together, turn it on, and it will run for you. I have never seen this first try, first serve situation.

Why are LNAs so expensive?

Profit is one reason, but in past years they've been extremely expensive because 20% of the LNA cost is materials and the rest is labor, much of which is because a design engineer or a microwave engineer has to sit and tune the LNA for proper specifications. This is extremely expensive at the rate of pay for engineers. The common laborer on a construction test bed is not able to bring a low-noise amplifier to specifications by simply plugging in the transistor, soldering it down, and shipping it out. It has to be tuned with precise instruments. The prices are dropping now, however, and they have come down almost two-thirds in the last 3 years.

Will the open-end LNA work with no feedhorn?

Yes, it will. You can take the common commercial LNA with the open mouth and omit the feedhorn; this works exceptionally well for a .3 to a .4 dish. Now, if you go much larger than a .45 or .5 dish, where they're flatter, then you'll want some sort of a funneling device on the front of your horn such as a square-flanged horn or a funnel to create a more directional beam from the focal point to the dish.

Is a 60-dB LNA better than a 30-dB LNA?

No, I wouldn't say so, not in natural use if the mixer is within the vicinity of the low-noise amplifier. If you're going to put your mixer inside the house and run 60-80 feet of coax or heliax to the mixer, then you need some extra dBs from your LNA and gain to pump the signal down the coax, but in effect they're equal in quality. A lot of people will think a 60-dB gain is better than a 30-dB gain. As far as the noise level goes, that is established by the first transistor amplifier of the GaAsFET LNA, and therefore stages added behind it do not improve the noise figure. They improve the ability of the low-noise amplifier to push the rf further down the coax without getting back down to an unworkable level at the other end of the coax.

My LNA works all right at night, but is very noisy during the day; why is that?

It sounds like you have a heat problem inside the LNA where the chip capacitor is separating and/or closing due to the heat and expansion of the circuitry. Normally the day and night transition is not noticeable on a TV screen unless you're a very particular person and see more sparklies during the day than you do at night. But if this is the case, it's usually due to the temperature of the LNA, and its circuitry is failing during the day. The other type of interference that comes during the day is unassociated with temperature, light, or conditions of the sunspot cycles. The satellite noise figure is due to its position relative to the sun on its receiving antennas and whether it's charging its batteries or not. And all these parameters influence noise during the day.

One of the biggest clues to terrestrial interference is the fact that it's usually more predominant during the day than at night due to the fact that telephone traffic is a lot heavier during the day. The deviation is higher due to the volume of FM traffic that is coming out of the terrestrial interfering signal and deviates further into the video portion of the band of the particular channel that you're watching. Therefore, you'll notice the interference is heavier during the day than it is at night. If around 9 or 11 o'clock at night, when telephone volume drops off, the TV gets more and more clear, then you can suspect that you have terrestrial microwave interference, and I would go look for it with a spectrum analyzer at that point.

What is a dc block and is it really needed?

Yes, most of the commercial LNA manufacturers require that the dc power for the LNA be fed through the coax from the center conductor—this being a plus 15 to a plus 28 volts in some applications. In order to put the dc onto the coax going up to the LNA and at the same time have the rf from the LNA coming down that coax, you must divorce the two from each other at the mixer. A dc block is simply a capacitor, usually in the neighborhood of 1000 pF, inserted into the signal path allowing the rf to go through but keeping the dc on the LNA side of the stripline. An rf choke in the neighborhood of 5.6 or 10 millihenries is used to divorce the rf from the dc bias line that comes from the house. This enables you to have just one cable going to the LNA.

Do holes in the waveguide hurt anything?

It depends on how large the holes are. If they're no larger than one-eighth to one-quarter inch, they don't have very much effect if there are only one or two in the waveguide. I have quite a few holes in the home-built waveguides that I've used and I can see no difference whether I leave them open or cover them.

Do waveguide flanges have to be airtight?

The only reason that you would need an airtight or sealtight flange between waveguide joints is to make sure that you don't interfere with another system. If you have a high-power oscillator feeding down one of these waveguides or if you were receiving side interference from terrestrial microwave or something of this nature, then airtight flanges are needed. At the low level of signal that we are talking about, the normal, compressed, bolted-together waveguides are extremely efficient. The amount of enhancement gained by goldplating, sealing, soldering, and shimming the flanges is nearly useless. Moisture seepage or air seepage might be another consideration if you're having condensation problems inside your waveguide, but most waveguides are open. My waveguide is open and has been for three years.

How much gain is necessary for a "perfect" picture?

For a perfect picture, something in the neighborhood of 30-36 dB is usually needed. The LNA output must be sufficiently strong to drive the mixer stage. The mixer diodes, if not driven properly, will add appreciable noise to the system. This dictates about 33-dB minimum.

Why do some people use round horns and others use square horns?

A long time ago it was understood that you get an easier impedance match and less loss with a square horn. I'm not sure whether that is true, but square horns do have one distinguishing factor: The pick-up probe and the impedance matching tend to be consistent in single-mode operation. Hence the square waveguide is heavily used in military and commercial applications.

Circular waveguides collect an equal amount of E and H fields, these being perpendicular to each other. That is, when the wave enters the dish, the E and H fields are perpendicular. The E field is the electrostatic field and the H field is the magnetic field; therefore, in getting the maximum power transfer, you must have an equal amount of these two properties.

The circular waveguide more readily matches the configuration of the circular parabolic dish, the spherical dish, and also the wavefront you are trying to receive. The circular waveguide is therefore more receptive to the incoming wave than the square waveguide. In summation, the circular waveguide outdoes the square waveguide by approximately 1 to 1.5 dB. However, the transition that you use may cause a loss of .5 to 1 dB, so you may not gain anything by going from circular to square, depending on how well your transition works.

Why use a horn instead of a dipole?

The dipole by itself does not have the gain. What you are trying to do is focus the waves onto the probe in the rear of the waveguide. This gathering of the waves is extremely valuable when you're working with small signal levels of TVRO.

What is a scalar horn?

A scalar horn is simply an rf choke that keeps the signal from going over the outside of the waveguide or feedhorn and traveling back out toward the satellite. It also represents a sort of yagi antenna; a scalar horn's ribs re-radiate the wave toward the center of the waveguide, acting as an electrical funnel that catches and shoves the wave into the mouth of

the waveguide. The scalar horn applies most readily to a deep dish—low focal-distance-to-diameter ratio (F/D). The horn must "look" at a wider angle. The funnel-shaped horns are more directional and are used with a flat dish.

Why is the spherical-dish horn so much larger?

The focal point of a spherical dish is quite a long distance from the surface of the reflecting spherical and therefore a larger area has to be gathered in. It is as if you are traveling 12, 14, or even 32 feet away from the spherical antenna to catch the microwave signal. You're sort of like a catcher in a baseball game; you want to use a large glove to catch that little ball. The further away you are, the more directional you want your view of the antenna. Therefore, the broader the horn is, the narrower the beam is. So you want to catch this narrow beam, making the horn appear much larger in physical size. The diameter of the mouth is much broader than for a parabolic dish.

What horn do you use on a .3-F/D dish?

On a .3 you would use a wide-angle horn such as a sawed-off waveguide, a sawed-off piece of 2-inch pipe, or a rectangular commercial 229 waveguide. The waves spread very rapidly as they leave the mouth of the horn. This leads us to use the scalar horn as the best choice.

Is a gold- or silver-plated horn better than a copper one?

Gold or silver is better, but for all the cost of having the gold plating or the silver plating done, you will probably increase the signal only a tenth of a dB. So it's cost prohibitive to do this type of thing.

Are there any surplus horns?

"Surplus" is not really the word because you can go to any plumbing shop and find a 2-inch diameter circular piece of downspout copper tubing—and that is your "surplus" waveguide. There are square and rectangular waveguides. An abundance of them are being thrown out every month by AT&T into scrap yards where they're sold for scrap copper. (They knock off the brass fittings on the ends of the flanges for brass scrap.) There are probably tons of this lying around all over the United States.

How thick should the walls of the horn be?

Thick enough to withstand abuse such as from dropping it or from wild weather. In mounting it, you might bang into it, so you don't want it to distort readily with normal handling. Something like 24-gauge or 28-gauge copper is the thinnest you should use to make it rigid.

Can you use PC material for the horn?

I don't like to use PC board material because you solder to only one side at a time, leaving only thin copper to hold the corners together. Bracing it on the outside takes extra work such as putting brackets around it to hold it together. Generally speaking it will work reasonably well, although I think there's easier material to work with.

Where can I buy a horn?

That, I wouldn't know. Most horns can be built readily out of sheet copper drawn out on the kitchen table, cut with a pair of tin snips, folded, and soldered together, just as you would fold up cardboard to make a box for Christmas wrapping. Most of the amateur enthusiasts construct their own horns. ■

Beep!! Your TS-180 is off the air, Charlie.

Tony Ruepp HB9BLU
Ifangstr. 73
CH-8153 Ruemlang
Switzerland

The TS-180 contains a very effective swr protection circuit. If ever the swr exceeds a given limit, this circuit immediately cuts off your transmission and lights the LED. This state is held until you (or the VOX) release the transmit button.

When transmitting CW, I very seldom watch the rig. I rather "see" the letters and words passing by while staring at a hole in the air. Several times I did not realize my transmission had been cut off, but I learned it immediately when I returned to receive and heard my partner in another QSO wondering where I might have gone. My 40m and 80m antennas swing in the wind and often exceed the swr limit for a moment.

The following very simple modification guarantees gaining your immediate attention whenever the protection circuit has fired. It simply steals the sidetone and even recycles the protection circuit if you're operating in the VOX mode. It's an easy job to do (takes about 15 minutes and costs less than a dollar) if you follow the instructions carefully:

Prepare a diode (1N4148 or equivalent) and a piece of insulated wire (length about 50 cm). Strip one end and pre-tin it.

1) Remove the eight screws which secure the top cover.

2) Lift the cover slightly and unplug the speaker.

3) Remove the cover entirely.

4) Locate the protection-circuit LED above the digital frequency display. This LED is mounted on the LED unit. The leftmost pin on it is labeled PRL and a blue wire is soldered to it.

5) Make sure no other wires are touching that pin, then solder the prepared wire to it.

6) Bend the wire 1.5 cm behind the pin to the left. Bend it to the rear again after another 3 cm and follow the edge of the PLL assembly to the rear of the rig.

7) Bend it to the right again and cut it 2 cm from the CW key jack.

8) Strip ¼ cm and tin it.

9) Now carefully place the wire in its proper position and tape it close to its end to the chassis.

10) The CW key jack has 5 soldering lugs. Locate the one with the brown wire. (This wire leads to the STS pins of the i-f assembly.)

11) Solder the anode of the diode to the lug with the brown wire and the cathode (ring) to the added wire.

This completes the modification. ■

Build the Re-Fuser

It's a self-replacing fuse.
Why blow one when you can blow two?

A. W. Edwards K5CN
456 Glenmore
Corpus Christi TX 78412

I am sure that many technicians have made a trip to a remote, unattended electronic installation to restore some piece of equipment to service only to find that the problem was an open fuse. When the fuse was replaced, everything was normal; no other defect was apparent.

This article describes a circuit which will detect the open-fuse condition, give the load and/or supply time to recover, replace the open fuse with a good one, and announce the fact that the reserve fuse is now in service.

Fig. 1 shows the general circuit for a dc-powered unit. So long as the regular fuse, F1, is good, the heater element of the time-delay device is shorted out by it. Should F1 open, the heater appears in series with the load. After a delay period for the thermal device to operate, the TD switch contacts close and power is applied to the gates of SCRs 1 and 2. SCR1 conducts and places F2 in the main load line. If the load now is capable of proper operation, F2 will hold, restoring the equipment to service. The TD heater is again short-circuited, so it resets.

SCR2 may be used to activate a small oscillator, e.g., a Sonalert™ or other type. This modulator can be made to signal, via an rf carrier, that the main fuse has failed and that the system is in the backup condition.

The modulating system may be a periodic beep or a continuous tone. The Sonalert device can give local aural notice, as well as providing electrical modulation.

A relay arrangement might also be employed, with the relay coil across the main fuse. ■

FAST SCAN ***$249**

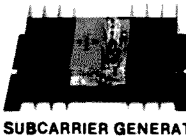
A modular approach . . . for your own custom-designed ATV system . . . . Here's how

TXA5-4 ATV EXCITER/MODULATOR. $89 ppd

This wired and tested module is designed to drive the Motorola MHW-710 module in the PA5 10 watt linear amp. The crystal in the 100 mHz region keeps harmonics out of two meters for talk back. The video modulator is full 8 mHz for computer graphics and color. Requires 13.8 vdc reg @ 70 ma. Tuned with xtal on 439.25, 434.0, or 426.25 mHz. Provision for sync expanding. Two frequencies available.

PA5 10 WATT ATV POWER MODULE $89 ppd

The PA5 will put out 10 watts RMS power on the sync tips when driven with 80 mw by the TXA5 exciter. 50 ohms in and out, plus bandwidth for the whole band with good linearity for color and sound. Requires 13.8 vdc regulated @ 3 amps



FMA5 AUDIO SUBCARRIER GENERATOR .... $29 ppd

Puts audio on with your camera video just as broadcast TV does at 4.5 mHz. Puts out up to 1 v p-p to drive the TXA5 or VM-2, 3, or 4 modulators. Requires low Z mic (150 to 600 ohms), and + 12 to 18 vdc @ 25 ma. Works with any xmtr with 5 mHz video bandwidth

TVC-2 ATV DOWNCONVERTER. . . . $55 ppd

Stripline MRF901 (1.7 db NF) preamp and double balanced mixer module digs out the weak ones but resists intermods and overload. Connects between uhf antenna and TV set tuned to channel 2 or 3. Varicap tunes 420 to 450 mHz. Requires + 12 to 18 vdc @ 20 ma. Super sensitive TVC-2L with NE64535 preamp (9db NF) stage $69 ppd

***TXA5, PA5, FMA5 and TVC Basic Module Pkg.**

No Smoking in the Ham Shack

Overvoltage kills solid-state finals. Protect yours for $1.00.

John J. Lapham, Jr. N7JJ
4718 18th NE
Seattle WA 98105

This two- or three-component addition to a power supply will give the experimenter a visual indication of an over-voltage condition and do it for much less than the cost of a meter (see Fig. 1). All that is required is a low-power zener diode, an LED, and (possibly) a low-wattage resistor.

For example, in Fig. 1, the unregulated voltage is 18 volts. Since a voltage-regulator failure could occur if there were a collector-emitter short, there conceivably could be 18 volts at the power supply output. Suppose the load can't safely operate at that potential for very long. By choosing the right zener, the experimenter can have an inexpensive visual indication of this condition. The mathematics are simple!

Remember Ohm's Law? E = IR. For this example, a zener is chosen which will reduce the 18 volts by the 1.5 to 1.7 volts which are used to turn on the LED: $V_{zener} = 18 - 1.7 = 16.3$ volts. In a normal output voltage condition, the zener will not conduct and the LED will not turn on, but if the output rises to the breakdown value plus the LED conduction value, the LED will light. But suppose you don't have (in this case) a 16-volt zener. Maybe you only have a 13-volt zener. What then?

Well, 18 V − (13 V + 1.7 V) = 3.3 V. What is going to drop that 3.3 volts? Remember that resistor? Now you can use it. The resistance must equal that 3.3 volts divided by the current through the conducting LED, in this case .02 Amperes. Using Ohm's Law we get: R = E/I, or R = 3.3 volts/.02 Amps = 165 Ohms. This value of resistance is then placed in series with the LED and zener to drop the excess voltage (see Fig. 2).

If the voltage is required to be monitored exactly, then a meter is the better choice. But if an absolute over-voltage value is the only concern, then this circuit could be utilized for around $1.00. It could be a bargain. ■

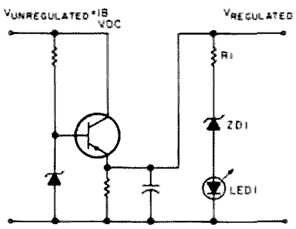

Fig. 1. R1, ZD1, and LED1 comprise the monitor circuit.

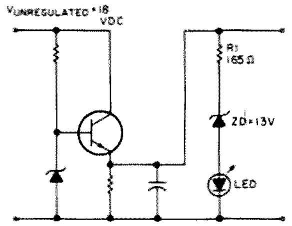

Fig. 2. The correct value for R1.

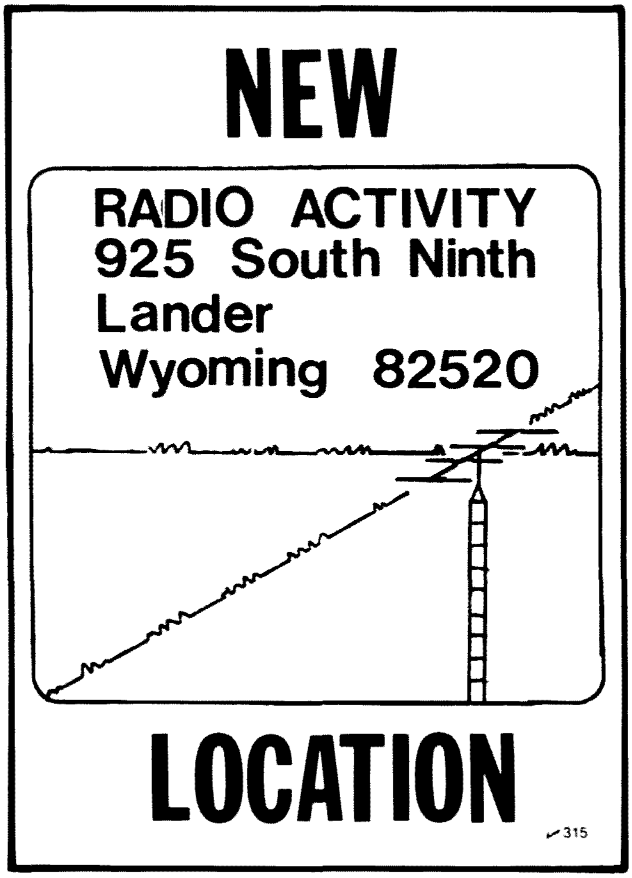

Tempo MARSer

Get the S-1 off those crowded ham channels. Expand your coverage above and below the amateur band.

Fig. 1. The Tempo S-1 transceiver.

Edison Fong WB6IQN
Signetics Corporation
811 E. Arques Avenue
Sunnyvale CA 94087

The Tempo S-1, introduced about two years ago, remains as one of the most popular VHF synthesized transceivers. This is because of its compact size, durability, reliability, and performance. This article will show that with some simple modifications, the radio's bandwidth can be extended to 140-155 MHz, thus covering MARS, mobile telephone, fire, police, etc. Although some degradation of performance occurs on the band extremes, no measurable degradation was observed within the amateur band. The few components and items needed are listed in the box.

The techniques presented here can be applied to similar transceivers such as the Icom IC-2A, but are much more complex with microprocessor-control radios such as the Kenwood TR-2400 and Santec HT-1200. Although the unit is capable of transmitting in the commercial band after the modifications, only authorized persons should do so. In addition, the modifications are not FCC-approved.

S-1 Background

The block diagram of the S-1 is shown in Fig. 2. The master oscillator is in a phase-locked-loop configuration so that only a single base crystal (6.82666 MHz) is used for the reference oscillator. This oscillator is fed through a programmable divider chip (NIS-103). Initially, this divider spans N=800-1600, giving the S-1 144-148-MHz capabilities. For example, the following divisions give the divider outputs and operating frequencies shown:

Division	Output (MHz)	Frequency (MHz)
N=800	1.33	144
N=1000	1.66	145
N=1200	2.00	146
N=1400	2.33	147
N=1600	2.66	148

NIS-103 does not directly divide the reference oscillator because NIS-105 contains other circuitry. The output signal is then mixed with the 43.1-MHz crystal oscillator. If the output of these two signals is summed and is fed through the vco consisting of the 2SK61 and then tripled via the 2SC1764, the output of the vco becomes 134.30 MHz. The vco generates the sum signal directly producing a clean signal as opposed to tapping the signal off the mixer

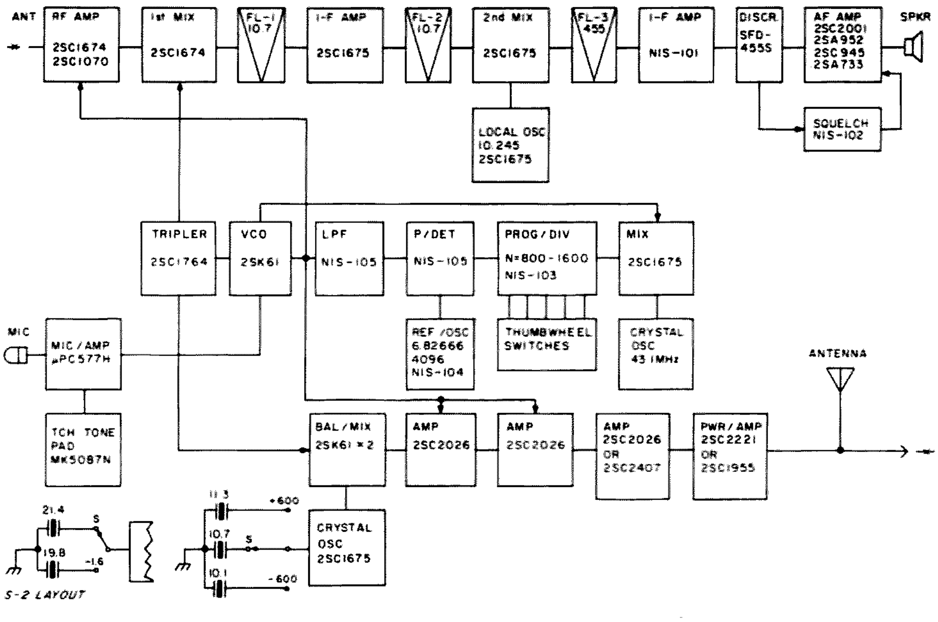

Fig. 2. Block diagram of the S-1.

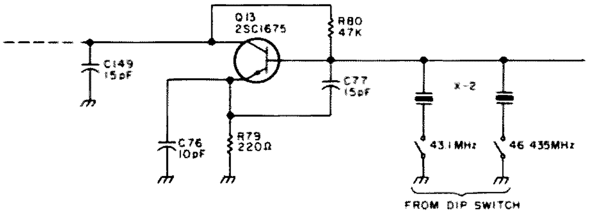

Fig. 3. Wiring configuration showing the switching of the two crystals.

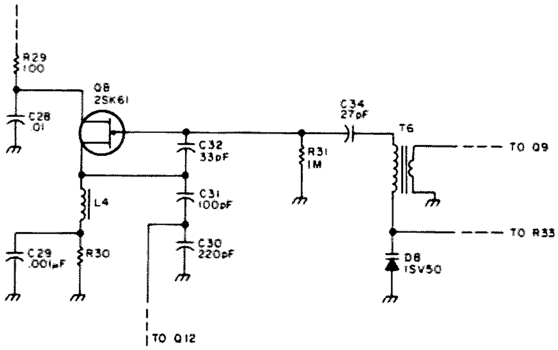

Fig. 4. Schematic of the vco. The only point at which the varactor diode can be connected is between C31 and C30 since the dc voltage will not disturb the circuit.

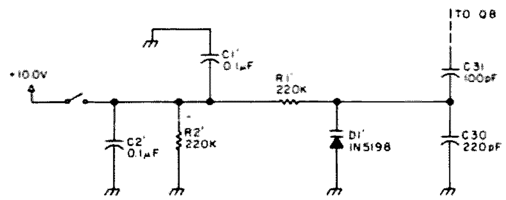

Fig. 5. Hookup of the varactor diode and how it is switched in and out of the circuit.

Fig. 6. Mounting of the varactor diode, C1', and R1' on the receiver board.

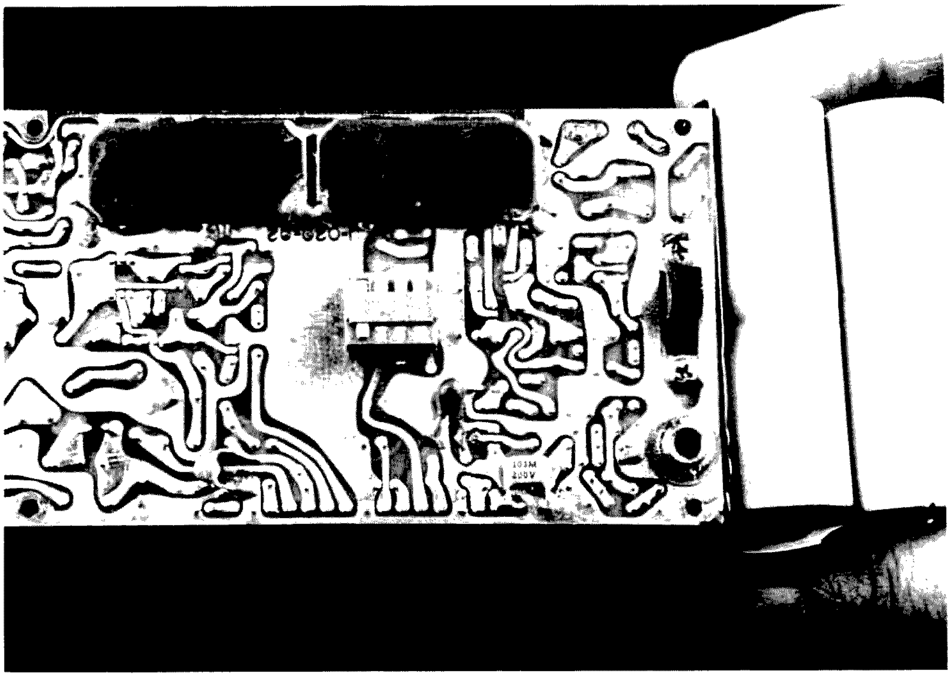

Fig. 7. Four-position switch mounted on the back of the transmitter board.

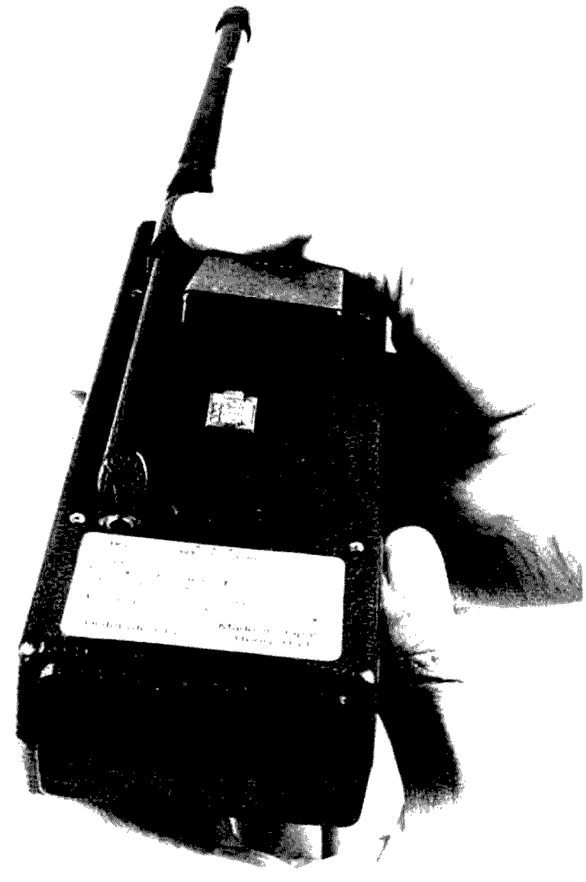

Fig. 8. The back of the transceiver showing the placement of the DIP switch.

(2SC1675), which will have spurious products within the band of operation. The two signals are compared by NIS-105 and a correction voltage is sent back to the vco (More on phase-locked-loop techniques can be obtained from Floyd Gardner's *Phaselock Techniques*, John Wiley and Sons, New York NY, 1966.) The signal is then fed either to the transmitter or receiver where 10.7 MHz is added on to it to obtain the 144.00 MHz shown in the example given above. For transmit offsets of +600 kHz, the crystal is 11.3 MHz, and for −600 kHz, the crystal is 10.1 MHz.

Extension to 140-150 MHz

The S-1 can easily be extended for operation from 140-150 MHz with minimum effort and no extra components. The programmability of NIS-103 is capable of N=0-2000. What prevents this action is not the electronics but the mechanics. Henry Radio is obligated to allow the radio to transmit only in the amateur band. This is done by placing rubber stoppers on the MHz section of the thumbwheel switches. With the unit removed from the housing, the three-section switch separates easily. On the switch furthest to the left, there are two rubber stoppers. Remove these and repack the switch. Coverage is now available from 140-150 MHz. Because of the varactor-tuned circuits in the transmitter and receiver, degradation in performance is minimal. With a dummy load into a Bird wattmeter, transmit power is still 1.5 Watts, and sensitivity is below 1 uV at the new band edges. No degradation was measurable within the amateur band.

Generally speaking, there is limited activity below 144 MHz, but from 148-150 MHz there is military, MARS, paging, and other action.

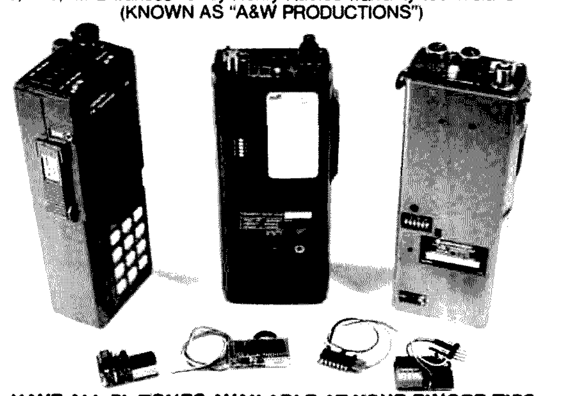
Extending the S-1 to 155 MHz

Most people would agree that 148-150 MHz is not where the major activity occurs. However, from 150-155 MHz, there are mobile telephone, paging, fire, police, ambulance, and other activities. A practical method of alternating the frequency is to change the 43.1-MHz oscillator crystal (X-2) to 46.433 MHz. This crystal will switch the synthesizer range to 150-160 MHz with direct readout. Unfortunately, the vco is capable of locking up only to 155.00 MHz. (This limit will vary from unit to unit.)

To switch the two crystals in and out of the circuit, remove X-2 and place it where the private line (PL) circuitry normally would go. Using RG-178 B/U (or RG-174, which is bulkier), connect one end to the receiver while the other end goes to the two crystals (43.1 or 46.433 MHz). For switching, a 4-position SPST DIP switch can be used. Since the crystal is grounded on the other end, it is best to disable the crystal by ungrounding it. Fig. 3 shows the wiring configuration. With the new

AT LAST!

This service will be available nationally. Lab tested & time proven modifications professionally installed in your amateur Handy-Talkie 2M, 220, 440, MH2 transceiver by Henry Radios warranty technicians (KNOWN AS "A&W PRODUCTIONS")



HAVE ALL PL TONES AVAILABLE AT YOUR FINGER TIPS

Outboard the dip switch! Have it neatly inlayed into the back cover of your Handy-Talkie making all 32 PL Tones Selectable at a moment's notice.

$25 Got your own PL? Send it to us with your Handy-Talkie unit and we do the professional installation for you.

$55 We will install a new PL and inlay the dip switch into the back cover of your Handy-Talkie ready to operate.

Send us your Handy-Talkie unit and a check or money order plus $3.50 for shipping and handling payable to **A&W PRODUCTIONS, INC.**

For **TEMPO** units the dip switch is inlayed into the Push-to-Talk bar. The **TEMPO S-15** will have the dip switch inlayed into the back cover.

$45 We will install a **NEW BATTERY BEATER** in your **TEMPO S-1, S-2, S-4, S-5 READY** to operate. Your New Battery Beater will use the same jack as the charger with no new holes and regulation circuits built into unit. Comes with Cigar Lighter Adapter with internal fuse.

CONTACT A&W PRODUCTIONS FOR SPECIAL MODIFICATIONS YOU MAY WANT TO HAVE DONE. WE SPECIALIZE IN THE TEMPO HANDY-TALKIES.

WE ARE AN OFFICIAL "TEMPO" REPAIR STATION
ALL WORK GUARANTEED FOR 30 DAYS. SEND YOUR HANDY-TALKIE AND A CHECK OR MONEY ORDER TO:

✓164

crystal switched in, it was found that locking of the vco extended only to 152 MHz. The range can be extended to 155 MHz by tuning T6, but the lower portion of the 2-meter band would not lock. This is an uncompromising situation, especially with the new repeater subband and fire and law enforcement between 153 and 155 MHz.

Is it possible to have the best of both worlds? Yes. This is the reason for the 4-position DIP switch rather than a two-position one. In order to extend the lock range of the vco, a varactor diode was incorporated.

Some general rules must be clarified before proceeding to any physical modifications. First, removing any components is out of the question. This is because the S-1 uses flow-through solder. The risk of damaging other components is high. Second, the varactor diode must be connected to a point where the dc voltage is isolated since the diode must be controlled by a dc voltage. The schematic for the vco is shown in Fig. 4. The node between C30 and C31 is the only point at which a varactor diode could be placed.

The 1N5148 varactor diode was chosen because of its range, 47 pF (no voltage) and 14.7 pF (minimum value), with about 10-volts reversed bias across it. A 220k (1/8-Watt) resistor was tied to Vcc to reverse-bias the diode. An additional resistor must be used to discharge the diode when the voltage is removed. Bypass capacitor C1' was placed next to R1' to prevent rf interference, and C2' was installed next to R2'. The final configuration appears as shown in Fig. 5.

In the 150-155-MHz area, the switch is closed, which reduces the capacitance on the varactor diode. In the 140-150-MHz region, the switch is opened. The two additional resistors should be 1/8-Watt to conserve space, but there is room for 1/4-Watt resistors. C1', D1', and R1' are placed at the bottom printed circuit board under the shield plate in parallel with C30, as shown in Fig. 6. This method is preferable to minimize lead inductance. R2' and C2' were mounted next to S3 since its lead inductance is not important. It is recommended that a frequency counter and rf generator be available so that T6 can be optimized for maximum bandwidth.

The uncommitted switch on the 4-position DIP switch can be used for subaudible tone or tone burst if desired. Mounting of the DIP switch is done on back of the transmit board, as shown in Fig. 7. A square hole is made on the back of the S-1 to access the switch, as shown in Fig. 8. Be sure to define the position of the hole carefully so that the position of the hole will match the position of the switch.

Useful Hints

Because the S-1 is so compact, rf tends to feed back into the critical sections of the transceiver. It was found that bypass capacitors (0.1 uF) installed in the supply leads in both the receiver and transmitter boards improved the PLL stability. As a general rule, do not solder the crystal case to ground. This can break the vacuum seal on most crystals and shift its frequency, and at times it may stop oscillating altogether. However, clamping the crystal to ground is permissible and is recommended. Also, placing a sheet of aluminum foil around the battery and then grounding it eliminates rf feedback into the touchtone™ pad.

Results

The original specifications of the S-1 are unchanged. In the low extreme (140 MHz) sensitivity is still below 1 uV, while at 155 MHz it was observed to be 1.5 uV, more than adequate for most applications. The vco lost lock at 156 MHz but was extremely stable below 155 MHz. By tuning T6, the upper or lower frequency extremes can be extended but the overall bandwidth is about 15 MHz. On transmit, at least 1.5 Watts was available at all frequencies. (Remember: A dummy load must be used when testing on unauthorized frequencies.) While switching from 140-150 MHz to 150-155 MHz, the unit must be turned off while the crystal is switched and then turned on again. This is because once the vco locks to a certain frequency, it is difficult to break lock and relock again when there is a 3-MHz difference between the two oscillator crystals.

The author would like to thank Glen Toth of Signetics for the photographs. ■

Items Needed

1—Crystal (same as for the AR-22C—X-3, 46.433 MHz)
1—4-position DIP switch
6"—RG-178 B/U coax or equivalent (RG-174 can be used but it is bulky)
1—Varactor diode, 1N5148
2—1/8-Watt, 220k resistors
2—0.1-uF bypass capacitors

The Tempo S-1 service manual can be obtained from Henry Radio, 2050 S. Bundy Drive, Los Angeles CA 90025, for $7.50

The crystal may be obtained from Ace Communcations, Inc., 2832-D Walnut Avenue, Tustin CA 92680, for $2.00

Orangevale CA 95622

CW and the Apple II

The simplicity of BASIC plus the speed of machine language equals a near-perfect Morse keyboard.

There are many good programs floating around for the Apple II microcomputer which will let one touch-type Morse code. However, CW isn't nearly as effective coming out of the Apple's itty-bitty speaker as it is coming out of your antenna. This article describes a very simple (and cheap!) interface for the Apple which should key most rigs.

The key to this interface is the neat little game I/O connector that Apple has so thoughtfully included with your computer. This connector is an ordinary 16-pin DIP socket with the layout shown in Fig. 1.[1]

Although there are 16 pins on this connector, only three of them are needed for this interface. These are: pin 1 for +5 volts, pin 8 for ground, and pin 15 as the keying output.

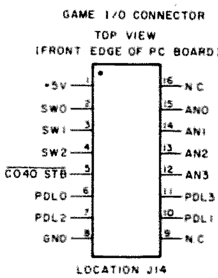

Fig. 1.

I next took an ordinary 16-pin solder-tail DIP IC socket (16¢ at James Electronics) and soldered wires to pins 1, 8, and 15 on it. I use this socket as a male plug, and plug it into the game paddle I/O socket whenever I get in the mood for CW.

Pin 15 is designated output AN0 by Apple, and is driven by chip F14, a 74LS259. The Apple manual suggests buffering this output, and Fig. 2 shows the buffering circuit I used to key my Ten-Tec Triton IV transceiver.

U1 is a single AND gate from a 74C08 CMOS quad AND gate (49¢ at Radio Shack). Q1 is a 2N2222 NPN utility transistor (10¢ at Radio Shack).

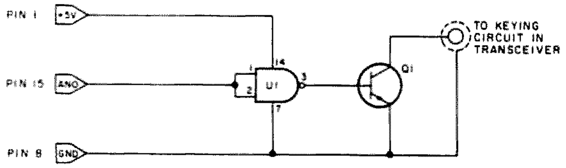

Fig. 2.

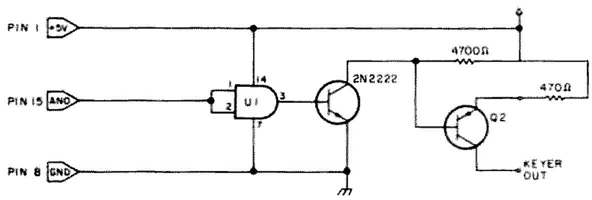

Fig. 3.

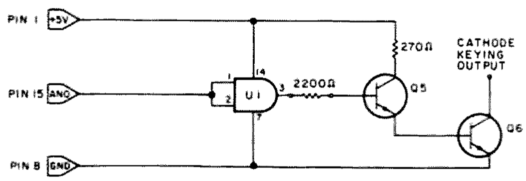

Fig. 4.

There are other combinations of parts that work which may even be cheaper than this circuit. However, these are the first ones I ran across in my junk box, and, as the old proverb says, "If it works, don't fix it."

One word of caution: If you use a quad CMOS chip, as I did, be sure to ground the inputs to the unused gates—otherwise the chip may malfunction. Thus, for the 74C08, you should ground pins 4, 5, 9, 10, 12, and 13.

My Triton IV is an all-solid-state rig employing low keying voltages that a 2N2222 can handle with ease. If your rig uses grid-block keying, a slightly different circuit should be used—see Fig. 3.

Q2 can be substituted, but should have a V_{ce} greater than the keying voltage employed in your rig. The 2N5401 and the 2N4888 can handle up to about 300 volts.

For a cathode-keyed rig, the circuit in Fig. 4 can be used.

Q5 is a 2N4123, and Q6 is a high-voltage, high-current silicon NPN power transistor such as the Delco DTS-801, -802, or -804.

The connoisseur of keying circuits may find the latter two of these circuits very familiar. They are borrowed from Jim Garrett's (WB4VVF) excellent article on the Accukeyer.[2]

Well, so much for the hardware end—the rest is free! (I spent 75¢ for parts for my interface. Add an extra buck or two if your rig requires one of the latter two circuits.) The only thing remaining is to add statements to your CW program which will tell it to turn the AN0 output on and off at the right times.

By POKEing a 0 into location −16296 (hex $C058), AN0 is set to zero volts. Conversely, by POKEing a 0 into memory location −16295 (hex $C059). AN0 is switched to +5 volts.

CW programs can vary greatly, but probably all of them, whether written in BASIC, assembly language, or machine language, will have one subroutine to send a dit and another subroutine to send a dah. If your program is in BASIC, then the statement POKE −16296, 0 should be added to your program as the first statement in both the dit-forming and dah-forming subroutines. Likewise, add the statement POKE −16295, 0 as the last statement in each subroutine. Also, it is a good idea to add the statement POKE −16296, 0 as one of the first statements in your program, so that output AN0 will be initialized to zero volts each time the program is run.

If your dit- and dah-forming subroutines are in assembly or machine language, the following commands will work. Insert the command:

```
AD 59 C0        LDA $C059
```

immediately before the command which starts the code element sounding. Likewise, insert:

```
AD 58 C0        LDA $C058
```

immediately after the command, which stops sounding the code element.

As a final example, here are a few details from my own CW program, which is based on "The Morse Master," *73 Magazine*, January, 1979, p. 114. A BASIC listing of the pertinent parts of my program is shown in Fig. 5.

The Morse code is held in an array A$(P), where 3s stand for dahs and 1s stand for dits. As each letter is typed on the Apple keyboard, the corresponding value in the array is returned. For example, when C is pressed, the value 3131 is returned from the array. The subroutine at 1000 then peels off the digits one by one from the left. If a 3 is present, the dah subroutine at 1300 is selected. If a 1 is present, the dit subroutine at 1200 is selected.

My dit and dah subroutines are almost identical. They each call the same machine-language subroutine at memory location 16002. This subroutine is listed in machine and assembly form in Fig. 6. In hex, 16002 is written as $3E82.

This machine-language program is almost identical to the tone-generator program shown on pages 43-45 of the Apple Reference Manual. Each time before it is called, two values must be POKEd into memory. The first is variable PP, which determines the frequency of the output tone through the speaker. This can be any number between 0 and 255 (I prefer 96) and this number is POKEd into memory location 16000 (hex $3E80). The second number required by the subroutine tells it how long the code element should be sent. In the dit subroutine, this is variable X, and, in the dah subroutine, I used variable T. This second number is POKEd into memory location 16001 ($3E81 hex). (I use X = 10 and T = 40 for a code speed of about 30 wpm.)

```

Fig. 6.

Fig. 7 shows a BASIC listing which will POKE the machine-language subroutine in Fig. 6 into memory at location 16002 (hex $3E82). One of the first statements in my main BASIC program calls this subroutine before any other action is taken by the program.

Well, that's it in a nutshell. If anyone has any problems, send me an SASE and I'll try to help. ■

Everyman's Audio Amplifier

Make this one-chip amp a permanent part of your test bench. It's an easy project for beginning experimenters.

Motivation seems to be a combination of need, circumstance, and availability. These all came together when my audio signal tracer died its final time, died when I needed to check a mike that someone said "doesn't sound like it used to."

I have long ago learned *not* to ignore good advice in small packages that come over the local repeater. The availability was provided by an IC, a Toshiba TA7205P that had been purchased from Digital Research, a good source of supply that I first met through *73*. The charm it held for me is that its pins will fit into one side of a standard 20-pin DIP socket.

The diagram of the finished product is shown in Fig. 1. The external parts count is low and non-exotic. The supply voltage range is wide enough to make it go from any small supply that you have around the bench, and it works "carside" quite well, running off a cable that goes into the cigarette lighter. The series RC network connected to pin 7 is the gain set.

As shown, there is ample gain to get a fair amount of noise out of the average mike. The volume control allows the handling of a good range of input levels, making it handy for many bench chores.■

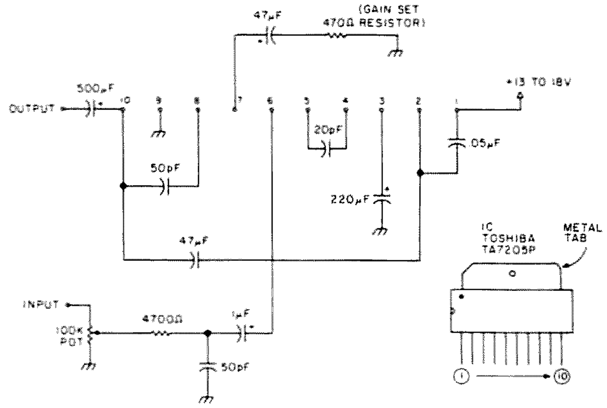

Fig. 1. Schematic of the general-purpose, one-IC audio amplifier.

COMPARE the HAZER™
with foldover + telescoping towers

- Antenna systems mount on Hazer-Hazer follows parallel to outside of tower - Raise to tower top or lower completely to ground level
- Safety - speed - convenience
- Ease to install and use
- Price
- For Rohn 20 & 25 tower
  Complete with winch 100 ft. of cable hardware and instructions

Award-Winning Program

Certificate hunters, cut your paperwork down to size. Let your Pet track your quest for excellence.

Here's a simple program for the Pet that was designed to keep track of what states have been worked on what bands for 5BWAS. For each state, the program records the callsign of the station worked on each band (80, 40, 20, 15, and 10 meters). You can display the entries, just the totals for one particular band, or the totals for all bands combined (mixed). The data is stored in a data file on cassette tape and takes about two minutes to load, save, or verify. The program also provides a way of changing or deleting any entry, if required.

The program was written to be flexible enough that it could be used for other awards records such as Worked All Zones (WAZ) or Worked All Continents (WAC). To change the program for another award, simply modify the values in lines 180-200 as required:

AW$ = The 3-letter award name (WAS, WAZ, WAC, etc.)

NE = The number of entries for the award—must be 50 or less due to the current Pet display limitations. (WAS = 50, WAZ = 40, WAC = 6, etc.)

IE$ = Entry input question used in line 770:
For WAZ you could use:
IE$ = "ZONE (01-40)".
For WAC you could use:
IE$ = "CONTINENT (NA, SA, EU, AF, AS, OC)"

K$ = The string of entry names each 2 characters long:
For WAZ you would use:
190 K$ = "010203......20",
200 K$ = K$ + "212223......40".
For WAC you would use:
190 K$ = "NASAEUAFASOC"
200 (deleted—not used!)

Program listing.

Reader Service for facing page ↙5→

Once these three lines have been changed, the rest of the program should not have to be modified.

The remainder of the program is very straightforward. Line 220 ensures that the Pet is in the upper-case/graphics mode and defines the data (D$) and totals (T) arrays along with the blank entry value (E$). Lines 260-340 display the program "menu" which allows the user to select the desired program function from those available. Lines 350-380 get the number of the desired function and check that a valid selection was made. Lines 400-420 then branch to the routine to perform the selected function, but the data must first be initialized or loaded from tape before any other function can be performed. This ensures that the data matrix (D$) has been set correctly before attempting to use any values contained within it. Each of the available functions is then performed by one of the routines in the remainder of the program.

The first time you use the program, initialize the data to clear all entries. Then enter each callsign for the appropriate QSO on each band for each state. You make the entries by first specifying the state to be entered. If you hit "RETURN" without making an entry, the program will return to the menu selection. If the state is not found (incorrect 2-letter code), you will be asked again for the band (80, 40, 20, 15, or 10 meters). If "RETURN" is entered without any data, you will be asked for the state again. If an incorrect band is entered, you will be asked for the band again.

When a correct state and band have been entered, the current entry for that state and band will be displayed. If you enter "RETURN" without any data, the current entry will be unchanged and you will be asked for the next state. If you enter a "D" followed by "RETURN", the current entry will be deleted (set back to periods). Any other data entered followed by "RETURN" is assumed to be the callsign to be entered for that state on that band. If the callsign is longer than 10 characters, you will have to reenter the callsign. All callsigns entered will have periods appended to make them 10 characters long before they are stored. The five callsigns for each state are stored together as one 50-character string to save memory space.

When all entries have been made, display the data on each band and check it correct. If required, go back and make any corrections. You also can display the totals and check for the correct number of states on each band. Before stopping the program, make sure that you save the data on tape. It's also a good idea to take the extra time to verify the data file, to make sure it was correctly saved. You might even want to save more than one copy on tape while you have everything in memory. Now you simply load the old data file the next time you want to add, correct, or examine anything. If you make any changes, don't forget to save the new data on tape. For those who want to go even further with their award records, you could keep separate data files for each mode (SSB, CW, RTTY, SSTV, etc.).

To answer the question before it's asked, for anyone too lazy to type in the program, I'll be happy to supply copies on tape for $2.00 each. However, *please send all requests directly to me* and not through the magazine. ■

Speed Demon

How fast was that? Find out with this wpm display for Heath's 1410 keyer.

Jerry Wayne Campbell K4ZHM
Rte. 4, Box 126 Barkley
Nicholasville KY 40356

In the following, I will describe a digital display I added to my Heath 1410 keyer to display the wpm setting of the keyer. The same principle can be applied to other keyers.

First, let's look at what we need to calculate the words-per-minute speed of the keyer. The *ARRL Handbook* gives the following formula for calculating code speed:

words/min = dots/min/25 = 2.4 × dots/sec

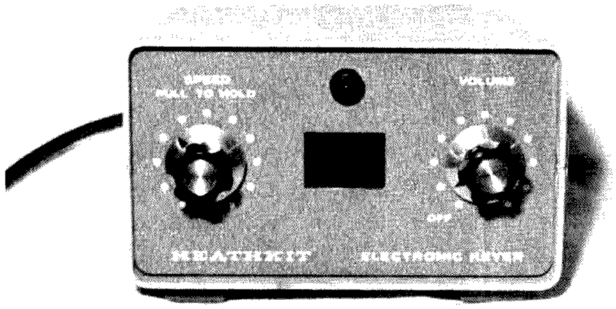
From the Heath 1410 keyer manual, we see that for each dot generated (space included), the clock in the keyer generates two pulses. The clock pulse rate is twice the dot rate. If we measure the clock pulses instead of the dots, the formula becomes:

words/min = 1.2 clock pulses/sec

Multiplying the clock pulses/sec by 1.2 is the same as measuring the clock pulses for 1.2 seconds. 1.2 seconds is 72 cycles at the 60-Hz power-line frequency; therefore, if we count the clock pulses for 72 cycles of the line frequency, we are effectively multiplying our keyer clock pulses/sec by 1.2. Thus, by counting the clock pulses from the keyer for 1.2 seconds, we can read the code speed directly on the seven-segment displays.

Referring to the timing diagram in Fig. 1, we see that by dividing the 60-Hz line frequency as shown (first by 6, then again by 6, then by 2, then finally by 2; see Fig. 2) we obtain a 1.2-second gating pulse. We now have the means to time the keyer clock pulses for 1.2 seconds and the count will update each 1.2 seconds. The reset pulse clears the counters 0.6 seconds prior to the counting interval. Send dots and/or dashes for over 2.4 seconds, and the readout will display for 0.6 seconds the speed at which the keyer is set.

Power, the 60-Hz line frequency, and, of course, the keyer clock pulses are all taken from the keyer. Refer to Fig. 3 and the Heath 1410 keyer manual for the fol-



The assembled keyer with the counter modification.

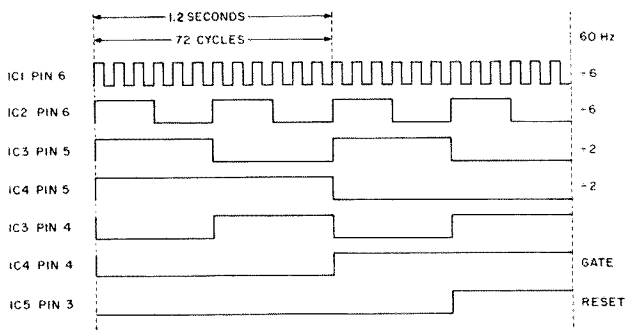


Fig. 1. Timing pulses appearing at various points in the circuit.

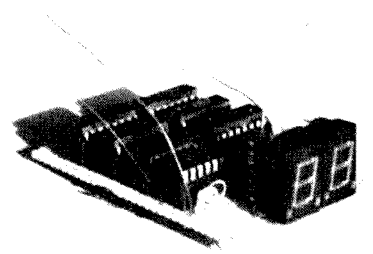
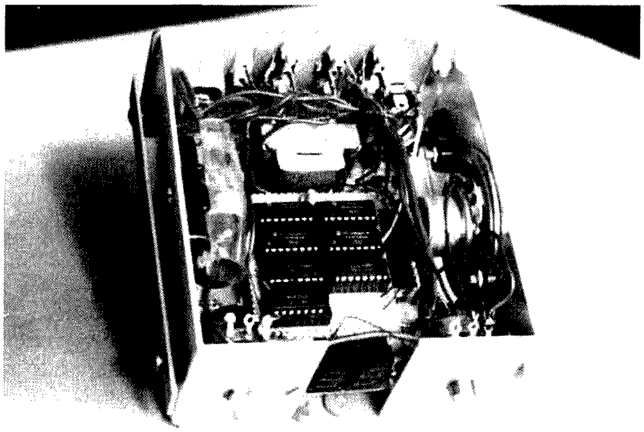


The completed counter board before mounting in the keyer.



The counter board is mounted using right-angle brackets and the mounting holes for the removed paddles.

BROOKLYN, N.Y. 11235

lowing connections. The keyer clock pulse is obtained from point D on the keyer speed control. The 60-Hz signal is obtained from either side of the secondary of the power transformer and ground. The resistor values shown, R1 and R2, are for the Heath keyer. A convenient source for the 5 V dc is the speaker lead that is connected to the 5 V dc supply.

I replaced the neon on-off indicator lamp with an LED. I then connected the inputs of the remaining 1/4 IC5 to pin 12 of IC3 in the keyer, and the output to the LED; see Fig. 2. The LED lights up on the mark portion of the code character.

When sending code, the display of the speed will vary. You are seeing the average speed at which you were sending in that 1.2-second interval.

There are several methods of housing the display. I use a Bencher paddle with my keyer, so I removed the keyer paddles from the keyer and took out the center post. I then mounted a red lens over the opening. The display and circuitry are then mounted behind the lens using the mountings for the removed paddle assembly. ■

Keyer on a Shoestring

Hams are cheap and so is this keyer. Big spenders will build the deluxe, two-chip version.

Joel R. Donaldson WB5PPV
17 Fenwick Drive
Laredo TX 78041

Most great keyers aren't very cheap, and most cheap keyers aren't particularly great. However, here's a fair-to-good one you can build for around $10.00 using all new parts. If you've got any sort of junk box at all, it should cost you quite a bit less. It's not iambic or self-completing, it lacks contest memories, weight control, and a few other bells and whistles, but it is simple, draws very little current, fits nicely into a small package, and is capable of sending good, clean CW. A keying transistor and floating ground make it usable with just about every modern rig, and a sidetone circuit can be added easily if your rig lacks one. In short, it makes a good first keyer or a nice second circuit for the vacation or QRP set.

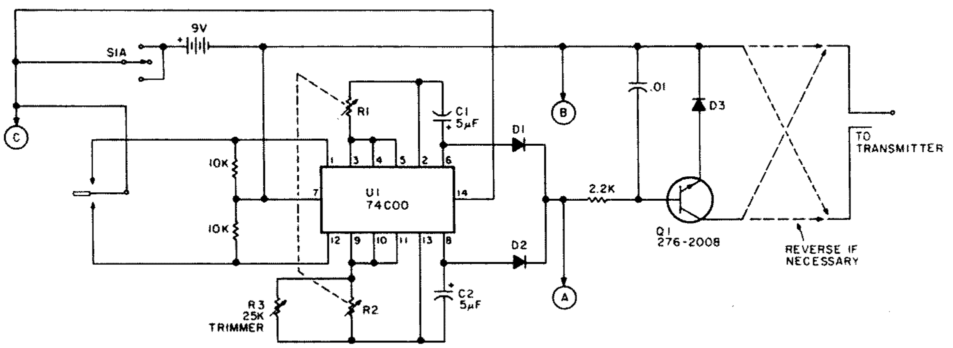

Fig. 1. One-chip keyer circuit. The entire circuit must be isolated from the enclosure. R1, R2—30k or 50k "stereo" linear taper dual pot. D1, D2, D3—any silicon diode. Q1 shown is a Radio Shack part number.

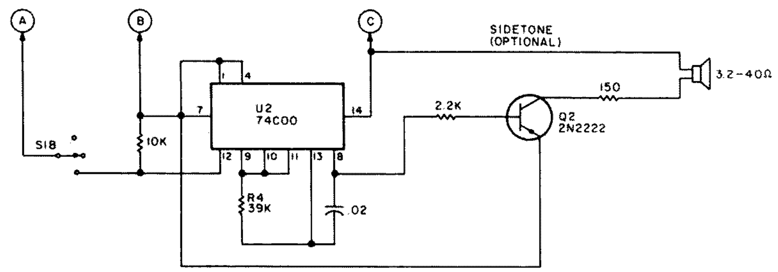

Fig. 2. Optional sidetone circuit connects to the keyer at points A, B, and C.

As shown in Fig. 1, the whole keyer is built around a 74C00 quad NAND gate which is connected to form two independent oscillators. The frequency of each oscillator is dependent upon a capacitor (C1 for one, C2 for the other) and a resistor (R1 for one, R2 for the other). By simultaneously varying R1 and R2, both oscillators can be sped up or slowed down, and a third resistor (R3) makes one of the oscillators run a

fixed percentage faster than the other, thereby providing a definite dash-to-dot ratio. The output of both oscillators is connected to the sidetone (if used) and to Q1, the keying transistor, through D1 and D2, which prevent one oscillator from interfering with the other. Q1 conducts whenever either oscillator is in the "on" state, thus keying the transmitter in step with the oscillators.

The sidetone circuit (Fig. 2) also consists of a 74C00 connected as an oscillator, but with R and C values changed so as to produce an audio-frequency tone. The output of this oscillator is switched by Q2, which provides enough drive to power a small speaker. The pitch of the sidetone may be changed by using a slightly different value for R4. The sidetone circuit connects to the keyer at points A, B, and C.

I mentioned earlier that this circuit has a floating ground. As shown on the schematic, no connections are to be made to the keyer cabinet. This eliminates expensive and hard-to-find reed relays, lowers power consumption, and sidesteps the need to modify the keyer whenever a different transmitter is used. Also, it is suggested that you stick to a battery to power your keyer unless you are certain that your power supply is isolated from ground. When connecting the keyer for the first time, it may be necessary to reverse the two keyer output leads to prevent the transmitter from being keyed all the time (wrong polarity to Q1). After the correct way has been found, a connector can be soldered on.

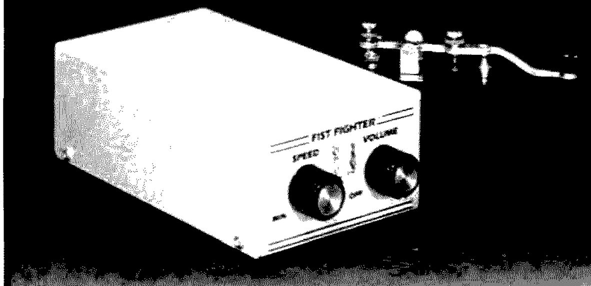
Adjustment consists of merely trimming R3 until the dits are about one-third as long as the dahs. Once this has been done, it will probably never have to be done again, since this ratio stays about the same over a fairly wide range of keying speeds and battery voltages. However, if it is anticipated that several operators of widely varying proficiencies will be using the same keyer, it might be better to make R3 a front-mounted control or at least provide a hole in the cabinet for quick screwdriver adjustments.

It seems kind of pointless to blow a considerable amount of money on a keyer paddle when the actual circuitry costs so little, so I would like to suggest a rather unoriginal but appropriately frugal alternative. It consists of a short piece of steel packing strap or hacksaw blade sandwiched between two telephone switch or relay contacts. The packing strap or blade is scraped clean of all paint in the contact area, and a piece of paddle-shaped Plexiglas™ which protrudes through the front of the cabinet is bolted to one end. When the paddle is moved in either direction, the strap touches one of the contacts. The strap need not make a perfect connection for the keyer to operate, since the CMOS oscillators will operate even with several thousand Ohms of contact crud. The strips of phenolic that insulated the switch or relay before modification are used in the same application; they make sure that neither the strap nor the contacts make an electrical connection with the cabinet. Fig. 3 shows one possible arrangement for the entire keyer, including the paddle.

Rf shielding for this circuit is not too critical; the prototype worked fine with no case at the 100-Watt level. I used a 1- by 1½-inch piece of perfboard for the keyer circuit, and the sidetone was added as an afterthought on another small piece of board. A center-off switch was used to control both the keyer power and sidetone, as the HW-101 already has a sidetone built in.

With the cost of amateur radio equipment what it is today, CW just has to offer one of the best potentials for having a lot of fun without spending a lot of money. Vintage CW rigs abound on the used market, and a good QRP rig can be purchased new without going too far into debt. Costing about as much as a cheap microphone, this circuit reflects the same spirit of fun on a shoestring. Use and enjoy. ■

NOT-A-KEYER



The FIST FIGHTER™

Using a straight key or "bug?" Then send your code with the Fist Fighter, and make it sound perfect. "Swing" and ragged edges are filtered out and your dots and dashes are always timed, 1:3. No new hand motions or special key needed, so you'll send code like a pro in no time. Great for novice or old-timer.

Price: From $59.95

I Got My Ticket! Now What?

A look at what Elmer forgot to tell you.

For many recently licensed hams, trying to operate a new ham station is just as difficult as learning the code or studying for the written exams. Anyone who has ever been involved in a licensing class knows people who have gotten licenses and set up stations, but never quite made any contacts on the air. New hams have many questions about operating. The following are some of the more common ones.

Local Time	80	40	Band 20*	15	10
6:00 am					
9:00 am			DX		
Noon			DX	DX	
3:00 pm	Local		DX	DX	DX or Local
6:00 pm	Local/ Ragchew	Local/ Ragchew	DX	DX	DX or Local
9:00 pm	Crowded	Crowded	DX/ Crowded	DX	Local/ Ragchew
Midnight	Ragchew	Crowded	DX/ Crowded		

***If allowed by license class**

Fig. 1. "Best bet" operating frequencies for a newcomer (1981-82).

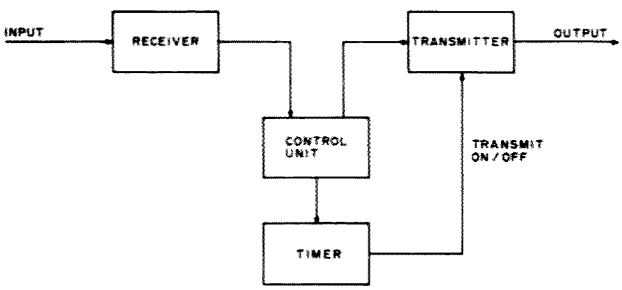

Fig. 2. Typical repeater.

I have had my station set up for a month and have managed to make just one contact. How come?

Let's assume your rig is working. The problem could be where and when you are trying to operate. For example, on a Friday or Saturday night, 80 and 40 meters (Novice band) are jammed and just about everyone has a problem. If you try 10 meters and the band is closed, you still won't work anybody. The trick is to pick a band and a time when there are a number of stations on, but the QRM is not overwhelming. Try 40 meters in the late afternoon, 15 in the early evening, or 10 on a Sunday afternoon (see Fig. 1).

Should I call CQ or just listen?

Use common sense. If you tune around for a few minutes and don't hear anyone calling, you can try a CQ, but pick a quiet frequency and limit your CQ.

Why limit it? I thought the traditional 3×3 or even a 3×4 was a good idea.

Look at it from the listener's point of view. If I hear you calling CQ for a long period of time and get tired of listening to you call, I won't want to reply to you. If you are that boring with a CQ, think how boring you would be in a QSO. With today's equipment, just call "CQ CQ CQ de WA1WTB WA1WTB," repeat once, and then K. If there is no answer, you can always try again.

You said to pick a quiet frequency. How can I tell if no one is using it?

Assuming you don't hear anything, just send QRL or IE. On voice, say "Is this frequency in use?" If there is no reply, you are perfectly correct to assume you can transmit without bothering anyone.

Am I better off operating CW or SSB to start with?

I am not sure what you mean by "better off." Assuming license class is not a consideration (you have more than a Novice license), try operating both and see what you like. Sideband initially takes less effort to operate but the frequencies are more crowded during prime operating hours. You usually can do better with DX on CW without fighting everyone's kilowatt.

What if I want to join a QSO that is already under way?

Let's be very blunt about it. In some cases, you won't be welcome. Hams are a cross section of people, no more and no less. However, on CW, a simple "BK" is enough to be invited in. On SSB, "May I join you? This is WA1WTB" or any English language equivalent is acceptable. Be careful of using "Break."

What is the problem with "Break?"

It used to be the normal and accepted way to break in but recently, especially on repeaters, "Break" or "Break Break" is used to indicate an emergency situation when you want to transmit in a hurry.

Is repeater operation different from other types of QSOs?

Yes. Almost every area or repeater is slightly different. It is a good idea to listen for a while before you get on a new repeater. Almost all are equipped with a timer which will cut you off if you talk for more than 1, 2, or 3 minutes, depending on the setting.

What controls the timer? I really don't want to get cut off in mid-sentence.

Some timers reset as soon as the repeater's receiver no longer receives a carrier. Others reset as soon as the repeater's transmitter shuts off. Some repeaters transmit a beep tone when the timer has been reset (see Fig. 2).

FREQUENCY	TRANSMITTER Preselect or Driver	Plate	Load	TUNER/MATCHBOX Input Cap	L	Output Cap

7200						
21000						
21100						
21200						

Fig. 3. Sample tuning chart.

Why limit the time for transmitting?

The primary reason is to force a pause between transmissions, and to do so often enough to allow anyone who wants to join the QSO time enough to transmit his call. In addition, it allows mobile stations to get into the repeater without having to wait any longer than a minute or two.

Do mobile stations have a priority?

Usually yes—both on repeaters and elsewhere. First, they are limited by their motion as to how long they will stay in range. Second, they are more likely to have seen an emergency situation or to need directions or other aid. Good procedure again follows common sense—let a mobile in quickly to find out if he has a problem.

I hear a lot about "kerchunking" repeaters. What is the story here?

Kerchunking is a very common practice of pressing your mike button to see if your transmitted signal is strong enough to bring up a repeater. Since it is a transmission without identification, it is technically illegal but it is also generally a worthless test. Quite often you can be on the fringe area of a repeater and be able to bring the repeater up but be too noisy to copy.

Is there a better way?

Sure. Key your mike and identify by saying, "This is WB1AJG—is anyone around?" If you don't make the repeater, nothing is lost. If you do make the repeater and no one answers, it doesn't make any difference since you won't have anyone to talk to!

When I identify myself on a repeater, should I use phonetics?

With a little experience you will know the answer to that question for your own call. If it contains an F, S, or other easily confused letter, you can use phonetics, but it is not usually done unless the station you are talking to does not repeat your call correctly. The same holds true for signal reports—they are not usually given unless asked for or you wish to indicate a problem.

Which signal reports are usually given on repeaters? Q5 S9 does not seem appropriate.

Since the signal strength you are receiving is due to the repeater and not due to the station you are talking to, the best you can do is tell if you are copying OK ("full quieting") or noisy. Some hams will say "50% quieting" which indicates they are copying half noise and half signal, but this non-technical use of "quieting" is a wild guess at best.

What about reports on other bands or when you are not using a repeater?

I suggest telling the truth. On CW, if you had a transmitter problem and your tone was not T9 or perfect, wouldn't you want the other guy to tell you? The

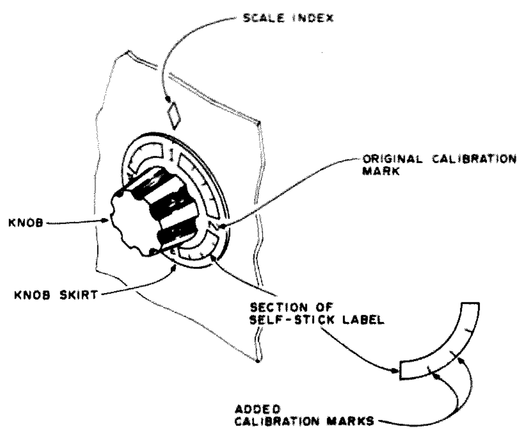

Fig. 4. Adding calibration marks to a skirt-type knob.

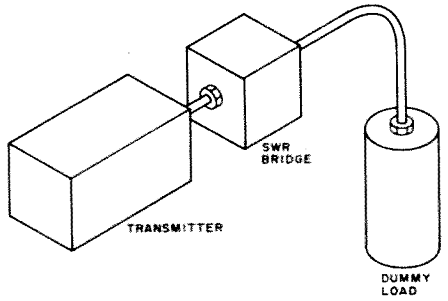

Fig. 6. Step 1: Tune up the rig into a dummy load.

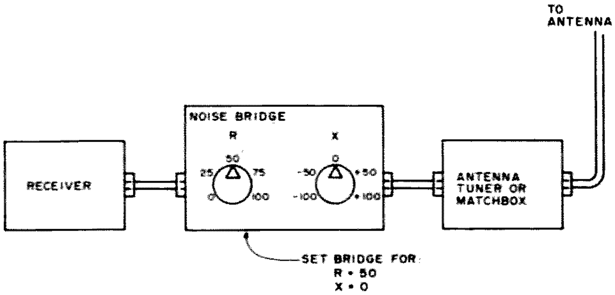

Fig. 7. Step 2: Adjust tuner to provide a 50-Ohm load.

same holds for asking the other ham to QRS or slow down.

Frankly, I was hesistant to ask. Won't a request to QRS brand me as a beginner?

Possibly, but we were all beginners once. Besides, what is the sense of sending "R" (I have solid copy) when you don't have the foggiest idea what the other station was talking about? I would rather be considered a ham who just is not too fast on CW than the character who sends: "R R R solid copy here OM please repeat your name, QTH, and my report." Besides, there are real ways to be branded a beginner.

For example?

Break into an emergency net when you cannot contribute anything. Keep making unsolicited, helpful suggestions to the station controlling the situation. An experienced ham would say nothing and listen carefully. If the net control station wants help, he will ask for it specifically.

Any other common things to avoid?

Sure. If you want to sound silly in the middle of a QSO, give out with an extended "H-E-L-L-O-O-O-O" to check your plate current or output power. Think how you must sound on the other end. If you feel absolutely compelled to make a check in mid-QSO, simply say to the other guy, "excuse me," put your rig in tune, and make a quick check. However, putting out a carrier for an extended period of time is a great way to be unpopular and cause unnecessary QRM. Besides, it's pretty rough on your finals.

I guess I don't understand. If I have to tune my rig and match it to the antenna, I have to transmit a carrier.

Yes, but you don't have to transmit it for very long. There are at least two ways to handle this problem. The first is to make up a tuning chart for your rig (and antenna tuner if you use one). Record the dial readings as you tune up every 50 or 100 kHz. Now, when you change frequency from one end of the band to the other, just set your knobs to the chart and you will only have to tweak them slightly to tune up, which can be done in 2 or 3 seconds (see Fig. 3).

Some of the knobs on my rig have calibration marks every quarter of a revolution. Is this good enough to allow me to preset them?

Probably not, but you can ink-in additional lines on the knob or use sections of self-stick labels. Place a small piece of self-stick label on the knob skirt (Fig. 4) or on the panel (Fig. 5) with the additional calibration marks inked in. Plain white paper fastened with rubber cement is also durable and easily removed later. If you draw lines on the paper or labels, you can protect them with artist's fixative or varnish.

What is the second way of tuning up without transmitting a carrier for an extended period?

Actually you can tune up without transmitting a carrier at all. It takes three pieces of equipment: your swr bridge, a dummy load, and a noise bridge. First, connect your rig (Fig. 6) through the swr bridge to a dummy load, and at the frequency you want to operate, tune up your rig into the dummy load. Then, connect the noise bridge as shown in Fig. 7 and set the resistance control on the noise bridge to 50 Ohms and the reactance control to zero Ohms. Next, tune your antenna tuner or matchbox for a minimum noise as heard in your receiver. If you have a transceiver, be very careful not to transmit with the noise bridge in the line or it will go up in a very rapid puff of smoke.

Now, remove the noise bridge and reconnect the transmitter through the swr meter to the antenna tuner, and you are ready to operate. What you have done is tuned your transmitter to its design condition of maximum power out into a 50-Ohm load, and you have made the antenna tuner and antenna look like a 50-Ohm load. Connect the two (Fig. 8) and you are ready to transmit, with maximum power out. You can also use this technique to make up a tuning chart so that you have to go through the procedure only once for each 50- or 100-kHz band segment you like to operate in. ■

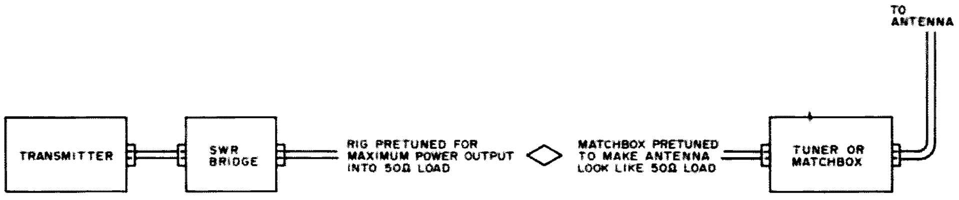

Fig. 8. Tuned up—without ever transmitting through the antenna.

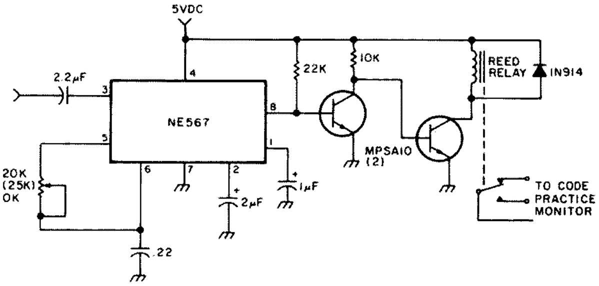
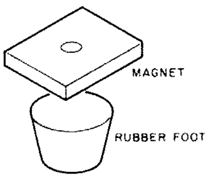
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

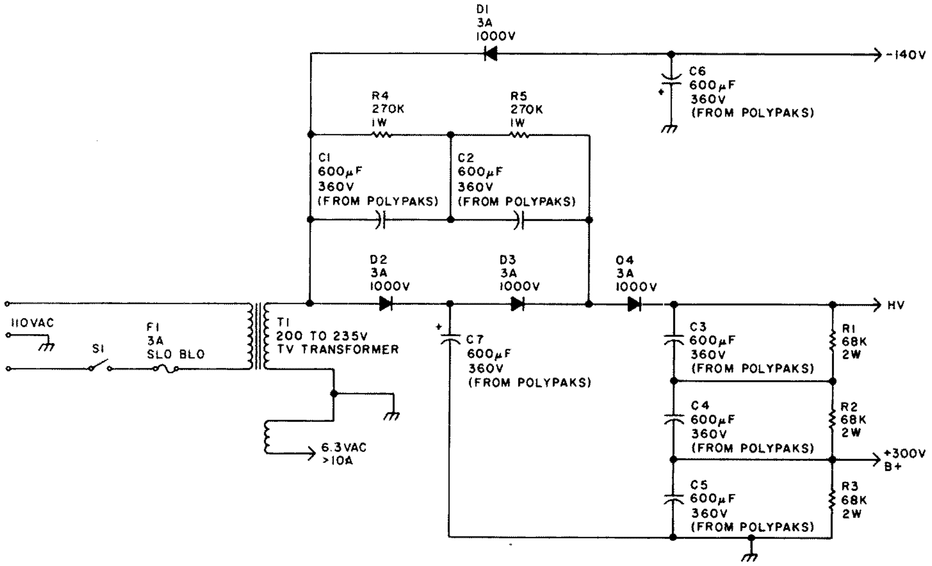
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



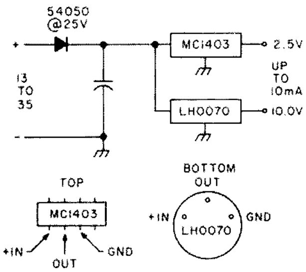
CW FILTER: This filter features a 40-Hz bandwidth and no ringing. To use it, tune your receiver so that the code-practice oscillator duplicates the signal you want to copy.—Ronald Folkert, Benton Harbor MI.



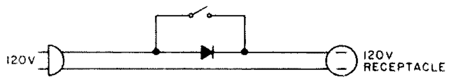
REMOVABLE MAGNETIC FEET: Gear such as Drake's TR-22C is fine for mobile or portable use but often lacks refinements like rubber feet that make it suitable for use in the shack. My solution to this deficiency was to epoxy several small magnets to some rubber feet and then stick them to the bottom of the radio. When the rig goes portable, just remove the feet. If you don't have any magnets handy, you can remove some from the magnetic cabinet latches sold in hardware stores.—Thomas Hart AD1B, Westwood MA.



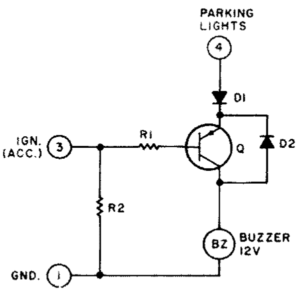
SUBSTITUTE TRANSFORMER FOR HEATH GEAR: The power transformer found in many newer TV sets can be used with a voltage-doubler circuit to provide up to 450 volts dc, as well as bias and filament voltages. I used this approach to replace the transformer in a Heathkit HX-10; it also should be suitable for the SB and HW series of Heath radios. (Note: Your rig's wiring may need to be modified if it has 12-V filaments.)—Terry Martin, Carrollton GA.

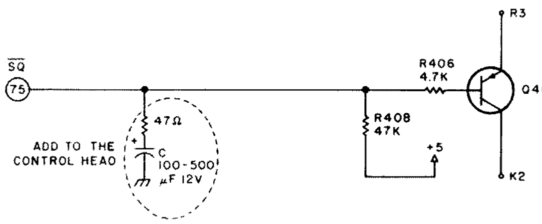


SIMPLE VOLTAGE STANDARD: This circuit gives you a voltage standard to check your VOM or electronic voltmeter. The MC1403 will deliver 2.5 volts while the output of the LH0070 is 10 volts. Both sources are accurate to one percent or better. You can get other voltages by using different members of the MC140X and LH007X precision regulator series. The diode can be anything rated over 40 mA and 60 volts piv.—J. T. Miller N6BM, Yucaipa CA.



HEAT CONTROL FOR A SOLDERING IRON: This handy circuit allows you to reduce the temperature of a soldering iron. Just place a diode in series with one side of the ac line. You can easily switch the control in and out by shorting the diode. The polarity of the diode doesn't matter. I used a 1N2070 diode rated at 400 volts, 0.75 Amperes. Any similar diode will do.—H. H. Hunter W8TYX, Columbus OH.





SCAN DELAY FOR THE AZDEN 2000: By adding a capacitor and resistor to the Azden 2000's control-head circuitry, you can have a delay before the receiver resumes scanning. There is approximately one second of delay for each 100 uF of capacitance added.—Hiam Sandel KB2IV, Flanders NJ.

HEADLIGHT REMINDER: If your headlights or parking lights are on, there will be 12 volts on terminal 4. If the ignition is off, terminal 3 will be at ground. When these two conditions are met, the transistor is turned on and the buzzer sounds. KA5CRI/9 suggests that this circuit can be built into a surplus seat-belt buzzer.—Steve Stout KA5CRI/9, Palatine IL.

CW REMEMBERED

Like it or not, we are witnessing the twilight of the CW era. After more than a century as a mainstay of electrical and electronic communication, CW is on the way out.

I make this statement purely as a rational observation. Nobody (including Wayne) has forced me to this conclusion. Just look at the facts. Thanks to microelectronics, radiotelephone transceivers need be no larger in size than CW-only rigs. Computer generated digital communication has now reached a point where it is inexpensive and portable. It's also faster and more reliable than code. CW—except as a means of personal enjoyment—is washed up.

Apparently, the FCC agrees with this point of view. Shortly you'll see the Commission remove the CW requirement from the Tech license. After that, it's just a matter of time (the year 2000 sounds good) before the feds eliminate all code requirements. In an age of 1s and 0s, dits and dahs don't make sense. Just as CW replaced spark, computerized communication techniques will replace CW.

By now your getting the feeling that I hate CW. Not at all. I've pounded the brass with the best of them. It's just that I, like most true radio amateurs, look forward to new challenges. And CW, while fondly remembered, should be relegated to the dusty attic of ham-radio history.

This month, we look back at CW and reflect upon the contributions it has made to our hobby. And if any of you have anything to say about what I've written about CW, remember: I passed a 20-wpm code test. Can you say the same?

Alton IL 62002

Does anyone have a recent list or roll tube chart for the Hickok 539B tube tester? It should be no more than 2 or 3 years old if possible.

Marvin Moss W4UXJ
Box 28601
Atlanta GA 30328

NEW TS830S for $150?

Yes indeed! Just add a Matched Pair of top-quality 2.1KHz BW (bandwidth) Fox Tango Filters. Here are a few quotes from users:

"... Makes a new rig out of my old TS830S!..."
"...VBT now works the way I dreamed it should..."
"...Spectacular improvement in SSB selectivity..."
"...Completely eliminates my need for a CW filter..."
"...Simple installation - excellent instructions..."

The Fox Tango filters are notably superior to both original 2.7KHz BW units but especially the modest ceramic 2nd IF; our substitutes are 8-pole discrete-crystal construction. The comparative FT vs Kenwood results? VBT OFF — RX BW: 2.0 vs 2.4; Shape Factor: 1.19 vs 1.34; 80dB BW: 2.48 vs 3.41; Ultimate Rejection: 110dB vs 80. VBT SET FOR CW at 300Hz BW — SF 2.9 vs 3.33; Insertion Loss: 1dB vs 10dB.

OPTIONAL CONNECTIONS

Fox Tango filters for RX and TX; Fox Tango for RX - Kenwood for TX; FT for RX - switch-select FT or K for TX; switch-select FT or K for RX/TX.

INTRODUCTORY PRICE: (Complete Kit)...$150
Includes Matched Pair of Fox Tango Filters, all needed cables and parts, detailed instructions.
Shipping $3 (Air $5). FL Sales Tax 5%

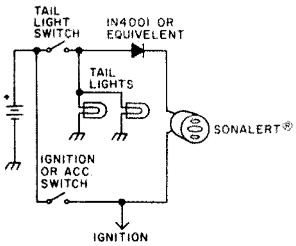
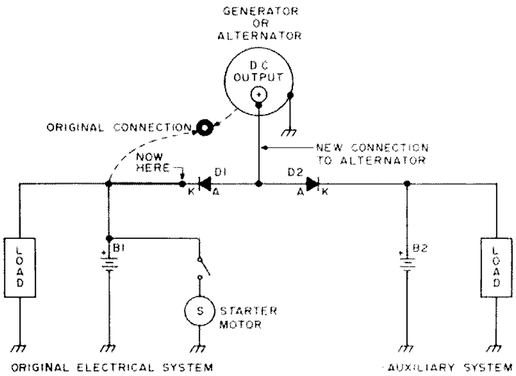
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

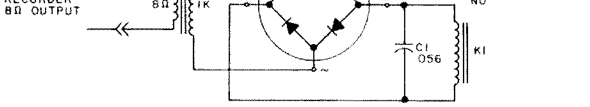
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



SIMPLIFIED HEADLIGHT REMINDER ALARM: The circuit uses just two components, one silicon diode and one Sonalert™ (4-28 V dc). Both of these items can be purchased surplus. The diode is a prevention device, protecting the signaling device and ensuring that the ignition switch is isolated from the circuit.—Richard S. Shepard AI5H, San Antonio TX.



DC AUXILIARY SYSTEM WITH ISOLATION: Presented here is a simple auxiliary battery system. Battery B2 is isolated from the primary battery by diode D2, and D1 is protected as well. Both diodes should be at least 40 Amperes forward current, and 50 to 100 piv. A heavy wire from the junction of the two anodes connects to the charging device terminal. Do not *rewire so that D1 is between the battery and the starter motor.*—A. W. Edwards K5CN, McAllen TX.



AUTOMATIC CQ CALLER: Record and send CQ or CQ DX—or any message—cheaply and easily. Begin by recording your message on a cassette tape. This recording will be used to drive the circuit. Mount the full-wave bridge astride the relay (K1). Solder the + and common leads to the coil leads. T1 is Superglued to K1. The assembly can be mounted inside a transceiver or outboard in a box. Wire the relay output to the keyjack. Install a jack to receive the audio output from the cassette. Endless-loop cassettes are available from Radio Shack. Five-minute cassettes are available from Pyramid Data Systems, 6 Terrace Ave., New Egypt NJ 08533.—Dave Nesbitt WD4AAW, Decatur GA.

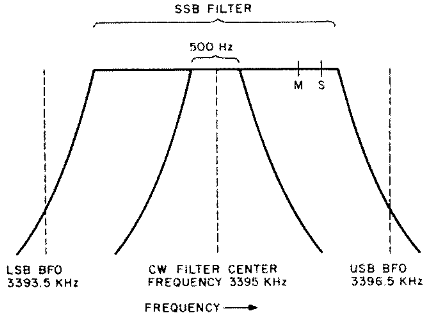


Fig. 1.

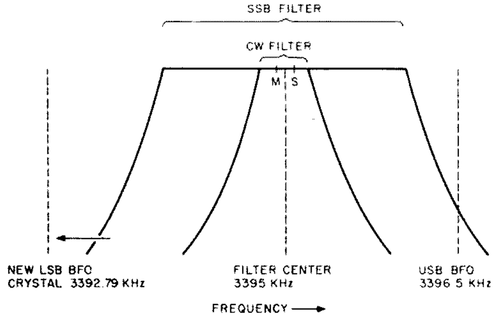

Fig. 2.

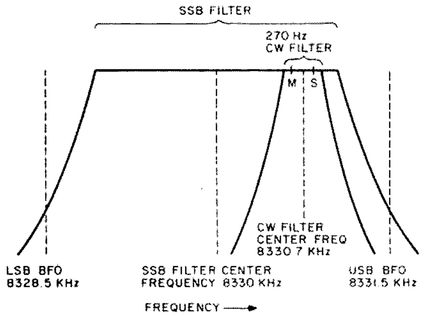

Fig. 3.

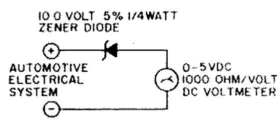
MODIFICATION TO THE KENWOOD TS-520S FOR AFSK: Fig. 1 shows the passband of the Kenwood TS-520S. By installing a crystal with a frequency of 3392790 Hz, the RTTY tones of 2125/2295 Hz will be right in the middle of the filters' respective passbands. See Fig. 2.

Fig. 3 shows the i-f filters. When installing the 270-Hz filter, follow the directions given in the manual except for the following: 1) install the filter in the SSB narrow position; and 2) jumper lead "A" to the "SSN" position and jumper lead "B" to the "SSB" position.

To set the filter, turn the switch to "CAL" and tune for a 2210-Hz tone (a scope is helpful, or else tune to a null on your RTTY tuning meter).—Richard Kulaga KA9EDX, Fond du Lac WI.



AN INEXPENSIVE EXPANDED-SCALE VOLTMETER: Use an unsealed 0-5-V-dc 1000-Ohm-per-volt meter movement. Solder a 10.0-volt, 5%, ¼-Watt zener diode to the positive meter terminal (this is located under the case). Use as short as possible a lead for good mechanical stability, observing zener polarity. Change the numbering on the meter face to 10-15 V dc. Use either a razor-pointed marking pen or dry-transfer numbers. Reassemble the meter and test it before installing it in your car. To ensure greatest accuracy, pre-check the zener and make certain that it is as close as possible to 10.0 volts.—Alan Christian WA6YOB, San Jose CA.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

DEARBORN MI
NOV 4

Encon Corporation, in cooperation with Solarex Corporation, will provide a free photovoltaic (electricity from the sun) seminar at 7:30 pm on November 4 at the Dearborn Hyatt Regency, Dearborn MI. A talk on the history, production, and applications of solar cells will inform and educate all those who attend. For reservations, contact Encon Corporation, 27584 School Craft Rd., Livonia MI 48150, (313)-261-4130.

SOUTH GREENSBURG PA
NOV 6

The Foothills Amateur Radio Club will hold its annual Swap and Shop on Saturday, November 6, 1982, at St. Bruno Church, South Greensburg PA. Tickets are $2.00 each or 3 for $5.00. There will be an indoor flea market and food. Talk-in on 146.07/.67 and .52/.52. For more details, contact Mario Carrera W3TTN, or write FARC, PO Box 236, Greensburg PA 15601.

SELLERSVILLE PA
NOV 7

The R. F. Hill ARC will hold its 6th annual hamfest on November 7, 1982, in the Sellersville National Guard Armory, Sellersville PA. Doors will open at 7:00 am for sellers and 8:00 am for buyers. There will be refreshments and heat. Talk-in on .28/.88 and .52. For further information, contact R. F. Hill ARC, Box 29, Colmar PA 18915.

CONCORD NC
NOV 7

The Cabarrus Amateur Radio Society, Inc., will hold its annual hamfest on November 7, 1982, from 9:00 am to 5:00 pm, at the Concord Boys Club, Spring Street, Concord NC. Admission tickets are $2.50 in advance, $3.00 at the door. Flea-market tables are $4.00; table space is $2.50. There will be bingo for the ladies, speakers, and forums. Hot food, beverages, and free parking will be available. Talk-in on 146.655. For advance tickets, flea-market tables, or space, send a check to CARS, PO Box 1290, Concord NC 28025.

NORTH HAVEN CT
NOV 7

The Southcentral Connecticut Amateur Radio Association's (SCARA's) third annual electronics flea market will be held on Sunday, November 7, 1982, indoors at the North Haven Recreation Center on Linsley Street in North Haven CT. Regular admission is $1.25; children under 12 with an adult will be admitted free. Sellers' spaces are $6.00. The best spaces will be assigned first. A limited number of free tables will be provided to the first reservations received. When those tables are gone, space will be available for selling from the floor or from your own table. Food will be available. Sellers may set up at 8:00 am, and walk-ins will be admitted from 9:00 until 3:00. For reservations, send check or money order payable to "SCARA" to Ed Goldberg WA1ZZO, 433 Ellsworth Avenue, New Haven CT 06511. Include an SASE for confirmation.

BANGKOK THAILAND
NOV 12-14

The Radio Amateur Society of Thailand (RAST) will hold the 12th annual South East Asia Network Convention (SEANET 82) on Friday, Saturday, and Sunday, November 12-14, 1982, at the Imperial Hotel, Bangkok, Thailand. There will be lectures, discussions, and commercial exhibits. For more details, contact RAST Secretary, PO Box 2008, Bangkok, Thailand.

NEWMARKET ONT CANADA
NOV 13

The York Region ARC will hold its annual flea market on Saturday, November 13, 1982, from 0800 to 1400 EST, at the Newmarket Community Centre, Newmarket, Ontario. Doors will open at 0630 for exhibitors. General admission is $2.00 (children will be admitted free of charge if accompanied by an adult). Refreshments will be available. Exhibitors' tables are $2.00 each. Talk-in on 142.52 (VE3YRA) and 147.225/.825 (VE3YRC).

FORT WAYNE IN
NOV 14

The Allen County Amateur Radio Technical Society, Inc. (AC-ARTS), will hold the 10th annual Fort Wayne Hamfest on November 14, 1982, at the Allen County Memorial Coliseum, Fort Wayne IN. Admission is $2.50 in advance and $3.00 at the door; children under age 11 will be admitted free. Regular tables are $6.00 and premium tables are $20.00. The Coliseum charges a $1.00 parking fee. Doors will open to the general public at 8:00 am and for vendor setups at 5:00 am. For further ticket or table information, write Becky Skinner KA9GWE, 9720 Pinto Lane, Fort Wayne IN 46804.

BILLERICA MA
NOV 20

The Honeywell 1200 Radio Club and the Waltham Amateur Radio Association will hold their annual amateur radio and electronics auction on Saturday, November 20, 1982, at the Honeywell Plant, 300 Concord Road, Billerica MA (exit 27 off route 3). Doors will open at 10:00 am and admission and parking are free. There will be a snack bar and a bargain parts store. Talk-in on 147.72/.12 and 146.04/.64. For more information, contact Doug Purdy N1BUB, 3 Visco Road, Burlington MA 01803.

CANTON OH
NOV 21

The Massillon Amateur Radio Club (W8NP) will present Auctionfest '82 on November 21, 1982, at the Nazir Grotto Hall, 6th and Dueber Avenue SW, Canton OH. Advance tickets are $2.50; at the door, $3.00. Doors will open at 7:00 am for setups and 8:00 am for others. The auction will start at 11:00 am. Talk-in on 146.52. For advance tickets or tables, contact Steve Nevel WD8MIJ, 1864 Massachusetts Avenue SE, Massillon OH 44646.

GREENSBORO NC
NOV 27-28

The Greensboro Amateur Radio Club will hold the second annual Greensboro Hamfest on November 27-28, 1982, at the National Guard Armory, Greensboro NC. The hours will be 9:00 am to 5:00 pm on November 27th and 9:00 am to 3:00 pm on November 28th. Pre-registration before November 12, 1982, is $3.00 and registration at the door is $4.00. There will be tables and tailgating available. Talk-in on 145.25, .19/.79, and .52. For pre-registration (please include an SASE) or more details, contact Russ Brandt KE4KL, 1301 Dayton Street, Greensboro NC 27407.

STONY BROOK LI NY
NOV 28

The Radio Central Amateur Radio Club will hold its fourth annual Ham-Central, 1982 edition, on Sunday, November 28, 1982, in the main social hall of Temple Isaiah, 1404 Stony Brook Road, Stony Brook LI NY (about 50 miles east of New York City). Doors will open at 7:30 am for sellers and dealers and at 8:30 for the general public. Admission is $2.00 and XYLs and children under 12 will be admitted free. Nine-foot tables are $5.00 each and half tables are $3.00. Features will include an updated antenna lecture by Art (W2LH) and Madeline (W2EEO) Greenberg, home-cooked hot food, and drinks. Talk-in on 144.550/145.150 (WA2UEC) and 146.52. For additional information, maps, and advance reservations, contact Scotty Policastro KA2EQW, 80 7th Street, Bohemia NY 11716, (516)-589-2557, or Bob Yarmus K2RGZ, 3 Haven Court, Lake Grove NY 11755, (516)-981-2709.

HAZEL PARK MI
DEC 5

The 17th annual Hazel Park Amateur Radio Club Swap and Shop will be held Sunday, Dec. 5, at Hazel Park High School, Hazel Park MI. Hazel Park High School is located on Hughes Street at 9½ Mile Rd., 1 mile east of I-75. Tickets are $1.50 in advance or $2.00 at the door. Tables are $1.00 per foot. Doors open at 8:00 am. Plenty of food and parking will be available. Talk-in on 146.52. For tickets, table reservations, and information, send an SASE to Hazel Park Amateur Radio Club, PO Box 368, Hazel Park MI 48030 or telephone (313)-398-3189.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ALARA CONTEST

Starts: 0001 GMT November 13
Ends: 2359 GMT November 13

Sponsored by the Australian Ladies' Amateur Radio Association, the contest is open to all licensed operators and SWLs throughout the world. YLs work everyone, OMs work YLs only. All bands may be used, phone and CW combined. Each station may be worked twice on each band—once on phone and once on CW. All contacts must be made in accordance with operator and station license regulations. No net or list operations, no crossmode, and no repeater contacts may be claimed.

EXCHANGE:

ALARA members send RS(T), serial number starting with 001, and ALARA number and name. Others (YL nonmembers or OMs) send RS(T), serial number starting with 001, and name.

FREQUENCIES:

Phone—3570-3590, 7100-7120, 14280-14300, 14180-14200, 21350-21370, 21180-21200, 28480-28520.

CW—3525-3535, 7010-7020, 14050-14060, 21125-21135, 28100-28110.

SCORING:

On phone—10 points for ALARA club stations contacted (VK2DYL or VK3DYF), 5 points for ALARA members, 3 points for YL non-members, 1 point for OMs.

On CW—double all point values shown for phone.

For SWLs—5 points for ALARA members logged and 3 points for YL nonmembers logged.

AWARDS:

Certificates will be awarded to the top scoring ALARA member in each country and VK call area; top scoring YL nonmember, OM, and SWL on each continent; and the top scoring VK Novice.

ENTRIES:

Send a single log containing date/time in GMT, band, mode, callsign worked, report and serial number sent/received, name of operator of station worked, and points claimed. Logs must be signed and should show full name, callsign, and address of operator along with final score claimed. Logs must be legible, either typed or printed, no carbon copies please. No logs will be returned and the decision of the contest manager will be final. Logs must be received by the contest manager by Dec. 31st. Address entries to: Mrs. Margaret Loft VK3DML, 28 Lawrence St., Castlemaine, Victoria, Australia 3450.

EUROPEAN DX CONTEST—RTTY

Starts: 0000 GMT November 13
Ends: 2400 GMT November 14

Sponsored by the Deutscher Amateur Radio Club (DARC). Only 36 hours of operation out of the 48-hour period are permitted for single-operator stations. The 12 hours of nonoperation may be taken in not more than three periods at any time during the contest. Operating classes include: single operator/allband and multi-operator/single transmitter. Multi-operator/single transmitter stations are only allowed to change band one time within a 15-minute period, except for making a new multiplier. Use all amateur bands from 3.5 through 28 MHz. A contest QSO can be established between all continents and also one's own continent. However, QSOs as well as OTC traffic with one's own country are *not allowed!* Each station can be worked only once per band.

EXCHANGE:

Exchange the usual six-digit number consisting of RST and progressive QSO number starting with 001.

SCORING:

Each QSO counts 1 point. Each QTC (given or received) counts 1 point. Multipliers will be counted according to the European and ARRL countries list. The multiplier on 3.5 MHz may be multiplied by 4, on 7 MHz by 3, and on 14 through 28 MHz by 2. However, contacts within the same continent only count as a multiplier of one per band (including 80 and 40 meters). The final score is the total QSO points plus QTC points multiplied by the sum total multipliers.

QTC TRAFFIC:

Additional point credit can be realized by making use of the QTC traffic feature. A QTC is a report of a confirmed QSO that has taken place earlier in the contest and later sent back to another station—the general idea being that after a number of stations have been worked, a list of these stations can be reported back during a QSO with another station. An additional 1 point credit can be claimed for each station reported.

A QTC contains the time, call, and QSO number of the station being reported, i.e., 1300/DA1AA/134. This means that at 1300 GMT you worked DA1AA and received number 134. A QSO can be reported only once and not back to the originating station. A maximum of 10 QTCs to a station is permitted. You may work the same station several times to complete this quota but only the original contact has QSO point value. Keep a uniform list of QTCs sent. QTC 3/7 indicates that this is the 3rd series of QTCs sent and that 7 QSOs are reported.

AWARDS:

Certificates to the highest scorer in each classification in each country, reasonable score provided. Continental leaders will be honored with plaques. Certificates will also be given stations with at least half the score of the continental leader or with at least 250,000 points. The minimum requirements for a certificate or a trophy are 100 QSOs or 10,000 points.

ENTRIES:

Violation of the rules, unsportsmanlike conduct, or taking credit for excessive duplicate contacts will be deemed sufficient cause for disqualification. The decisions of the contest committee are final. It is suggested to use the log sheets of the DARC or equivalent. Send a large SASE to get the wanted number of logs and summary sheets (40 QSOs or QTCs per sheet). SWLs apply the rules accordingly. Entries should be sent no later than December 15th to: DARC DX Awards, PO Box 1328, D-895 Kaufbeuren, West Germany.

EUROPEAN COUNTRY LIST:

C31, CT1, CT2, DL, DM, EA, EA6, EI, F, FC, G, GC Guer, GC Jer, GD, GI, GM, GM Shetland, GW, HA, HB9, HB0, HV, I, IS, IT, JW Bear, JW, JX, LA, LX, LZ, M1, OE, OH, OH0, OJ0, OK, ON, OY, OZ, PA, SM, S, SV, SV Crete, SV Rhodes, SV Athos, TA1, UA1346, UA2, UB5, UC2, UN1, UO5, UP2, UQ2, UR2, UA Franz Josef Land, YO, YU, ZA, AB2, 3A, 4U1, 9H1.

DELAWARE QSO PARTY

Starts: 1700 GMT November 13
Ends: 2300 GMT November 14

Sponsored by the Delaware ARC. Stations may be worked once per band and mode for QSO and multiplier credits.

EXCHANGE:

QSO number, RS(T), and Delaware county, ARRL section, or country.

FREQUENCIES:

CW—1805, 3560, 7060, 14060, 21060, 28160.

SSB—1815, 3975, 7275, 14325, 21425, 28650.

Novice—3710, 7120, 21120, 28120.

SCORING:

Delaware stations score 1 point per QSO. Multiply total by the number of ARRL sections and DX countries worked.

Others score 5 points per Delaware station worked. Multiply total by the number of Delaware counties worked on each band and each mode (maximum of 36 multipliers possible). The three Delaware counties are: Kent, New Castle, and Sussex.

ENTRIES & AWARDS:

Appropriate awards will be given to the top scorers. In addition, a certificate to all stations working all three Delaware counties. If you work all three counties and want the WDEL Award, send two 20-cent stamps and an address label. Mail logs by December 17th to: Charlie Sculley AE3H, 103 E. Van Buren Avenue, New Castle DE 19720. Send an SASE for a copy of the results.

SANDUSKY RADIO EXPERIMENTAL LEAGUE QSO PARTY

Starts: 1800 GMT November 13
Ends: 1800 GMT November 14

The 50th Anniversary of the Sandusky (Ohio) Radio Experimental League, Inc., will be observed and celebrated with a QSO party while members of the club operate on five amateur bands using the club call, W8LBZ. Frequencies will be: 28150 and 7125 for Novices; 3740, 7040, 14040, 21040, and 28040 on CW; 3910, 7265, 14280, 21360, and 28600 on phone. All frequencies plus/minus 10 kHz.

YELLOW THUNDER SMOKE SIGNALS

NEWSLETTER CONTEST WINNER

This month's winner is *Smoke Signals*, published by the Yellow Thunder Amateur Radio Club of Baraboo WI. The layout is superb and the articles are written in a humorous, low-key style. The newsletter is full of excellent news items from around the nation and overseas, making it appear more like a nationally-based newsletter. Also, a schedule of all the traffic nets in Wisconsin is included. The paper is full of interesting items, such as fox-hunt rules and updates on the members' activities. The editor, Jim Romelfanger K9ZZ, has done an outstanding job.

To enter your club's newsletter in our contest, send a copy to: Editorial Offices, *73 Magazine*, Peterborough NH 03458.

CALENDAR

Nov 6-7	ARRL Sweepstakes—CW
Nov 13	Australian Ladies' ARA Contest
Nov 13-14	European DX Contest—RTTY
Nov 13-14	W8LBZ QSO Party
Nov 13-15	North Carolina QSO Party
Nov 13-15	CQ-WE Contest
Nov 20-21	ARRL Sweepstakes—Phone
Nov 20-21	Trinidad and Tobago QSO Party
Dec 4-5	ARRL 160-Meter Contest
Dec 11-12	ARRL 10-Meter Contest
Dec 19	CARF Canada Contest
Jan 8	*73 Magazine* 40-Meter Worldwide SSB Championship
Jan 9	*73 Magazine* 80-Meter Worldwide SSB Championship
Jan 15-16	*73 Magazine* 160-Meter Worldwide SSB Championship
Jan 15-18	Hunting Lions in the Air Contest

All amateurs worldwide are invited to participate. A special QSL card/certificate will be sent to all who send their QSL card to the QSL Manager, W8LBZ, 2909 West Perkins Avenue, Sandusky OH 44870.

CQ-WE CONTEST

Starts: 1400 GMT November 13
Ends: 0500 GMT November 15

Sponsored by the Bell System Amateur Radio Fraternity, the contest is open to present and retired employees of Bell, Western Electric, AT&T, and subsidiaries of AT&T. Contact local interworks coordinator for logs and complete rules, or write Steve Wheatley WN8GUE, Bell Laboratories, 2525 Shadeland Avenue, PO Box 1008, Indianapolis IN 46206. Telephone: (317)-352-2442 at work or (317)-545-4029 at home.

NORTH CAROLINA QSO PARTY

1700 GMT November 13 to 0200 GMT November 14
1200 GMT November 14 to 0100 GMT November 15

This year's party is sponsored again by the Alamance ARC (K4EG). The same station can be worked on each band. Crossband and repeater contacts are not permitted.

EXCHANGE:

RS(T) and NC county or ARRL section.

FREQUENCIES:

SSB—3980, 7280, 14280, 21380, 28580.
CW—60 kHz up from lower band edge.
Novice/Tech—20 kHz up from lower band edge.

SCORING:

NC stations count one point per QSO and multiply total by sum of ARRL sections.

Others count 2 points per NC contact and multiply total by number of NC counties worked (100 max.). Add a bonus of 25 points for working the club station, K4EG.

AWARDS:

The top scorer in and out of state will receive the 1983 *Callbook* of his/her choice. Certificates to top scorers in each ARRL section.

ENTRIES:

Send logs and summary sheets showing essential details to: F. R. Ashley WB4M, 2731 Blanche Dr., Burlington NC 27215. Include large SASE for results. Mailing deadline is December 13th.

TRINIDAD AND TOBAGO QSO PARTY

Starts: 0000 GMT November 20
Ends: 2359 GMT November 21

The 9Y4 OSO party has been organized by the Trinidad and Tobago Amateur Radio Society, Inc., to commemorate 20 years of independence, 5 years as a republic, and 50 years of amateur radio. Use all bands from 10 through 160 meters on SSB, CW, or via satellites.

EXCHANGE:

The usual 5- and 6-figure serial number signal report plus a progressive 3-digit number starting with 001.

AWARDS:

A certificate will be awarded to any station working 5 or more 9Y4 or 9Y5O stations.

ENTRIES:

Logs must show date/time in GMT, station worked, and number sent/received. It is requested that a remittance of $2.00 or IRC equivalent be included with your log if you are eligible for an award. Entries must be postmarked no later than December 21st and addressed to: TTARS, PO Box 1167, Port of Spain, Trinidad, WI.

LETTERS

FEEDBACK

I know you like feedback, so here comes a long-postponed letter.

I still believe your magazine is the best all-around ham publication, but the cost is starting to concern me. You needn't defend it again. I'm fully aware that costs are continually rising. However, the saddle-staple binding of the July, 1982, edition definitely upset me. Is there an article shortage? Or are costs that high?

Speaking of articles, I had a few good ideas for short articles, but I fooled around and someone beat me to the punch—three times. Keep encouraging us to write. Even short articles are always interesting and often useful.

I particularly enjoy those about ham radio history and electronic history in general. I really loved that series your dad wrote a few years ago. Is it available in book form? By the way, how is the old gentleman?

In defense of your feelings about the code test, the July issue proves you have nothing against CW. I found the articles presented a fresh approach to some old gadgets, my favorite part of ham radio.

Incidentally, I preferred the table of contents cover when looking up old articles but I have enjoyed most of the photo covers also. My favorite was probably the chess board made up of vacuum tubes back around 1967. I once suggested a cover picture of sculpture made from the junk box. You did that a few years ago, too. I'm now working on a chess game from solid-state devices.

Another positive comment. No other magazine I have ever seen prints such an excellent mix of letters—pro and con—no matter what the subject.

Finally, I was very excited about the Braille DX Service ("Letters," July) but no address was given. I would like to pass this info to some sight-impaired friends. Could you please publish it?

Tom Grabowski K3SPY
Baltimore MD

Thanks, Tom. I don't think I get to a hamfest at which someone doesn't push me to get the Ancient Aviator articles by my father into book form. Our book division is working on this, although I'd like to get Dad to write more about some of the dirty work which went on during the time he was starting the first transatlantic airline. He's doing well at 86, spending half of his time in northern New Hampshire and half in New York. He really should write more. The saddle stitching is a little less expensive than the perfect-binding style, but the main reason for changing was our re-emphasis on construction articles. The saddle-stitched magazine lies flat on the workbench for reading or building, while the perfect bound style flops itself shut all the time. I've been pushing the fun of building gadgets for over 30 years now and I don't intend to stop. CW? The only thing I have against it is its being mandatory. I am convinced that if we made it a matter of ham pride, we would have more CW than ever. Many hams are obstinate people like me... as long as I am forced to do something they can go to hell. Call it Yankee perverseness, if you like.

The address you're looking for is BDXS, 8347 W. 6th Ave., Lakewood CO 80215; (303)-233-4335.—Wayne.

INNER PROCESSES

It is enjoyable to read such a practical and informative article as "Electric Health via Negative Ions" by Michael Windolph (July, '82). I especially liked the sensible statement, "Know what you are doing and be careful!"

I wanted to bring up a side point that might be of interest to your readers. To a large extent, we have become so accustomed to harmful environments that we have lost touch with our original, instinctive intelligence. It can be regained by patient, hard, and dedicated work, but it does take time.

To fully regain our instinctive intelligence to *know* when something is wrong, we must not only adjust our physical environment but also place our inner life in order. I find best-selling author Vernon Howard's books very helpful in this respect. Mr. Howard tells us that we have played a wrong note for so long that we have forgotten what the right note should sound like.

Using negative ions to enrich our air is 100% practical. To combine such simple and helpful projects on the practical level with intense observation of our inner processes would lead to better understanding of both worlds.

Keep up the good work. I look forward to every issue.

Tommy Russell
Boulder City NV

GEARVAKf

I can't tell you what a pleasant surprise and thrill it was to read that *The GEARVAKf Bulletin* had been selected Newsletter of the Month for August. It's gratifying to know that our "peculiar brand of madness" is appreciated by you folks out there in the real world of amateur radio publishing.

The *Bulletin*, of course, is a labor of love (we sure as hell don't make any money at it). It had its beginnings back in the distant past when my co-conspirators and I decided that too many hams, ham organizations, and ham publications tended to take themselves much too seriously. We started to poke fun at them—and ourselves—through the *Bulletin*.

We recognize that there is a serious side to amateur radio, but *The GEARVAKf*

Bulletin gives people a chance to take a "time out." With limited funds and distribution, we'll continue our periodic wackiness as long as possible. Your recognition has given us a chance to increase our readership some, and perhaps momentarily lighten the lives of our brother and sister hams. It helps us, too. Editing the paper is real therapy!

Anyway, on behalf of Dr. Felix R. Onehundredton, Dr. Elwood P. Lishnus, Dr. Avruell U. Harnishe, Ti-Grace Gaboon, Lelah Lilah Lowlou, and the rest of the GEARVAKI ruling mob, thanks from the bottoms of our warped little hearts.

Joe Ventolo, Jr. K8DMZ
Editor
The GEARVAKI Bulletin
Enon OH

SACRIFICES

Re Mr. Richardson's letter in the August *73* about rude tendencies in ham equipment salespeople:

I was formerly employed with one of the largest ham equipment dealers in the US, and I'd have to say that what he says is true to a certain extent. But give the guy behind the counter a break—there are a few legitimate reasons.

First, the salesguy is making a big sacrifice for the sake of his job; he has probably given up being an active ham. You can't talk, think, and eat ham radio all day and go on the air after work! No way. You get burned out sooner or later. Secondly, it was my experience that the amount of immature, rude nerds is disproportionately high in the ranks of hams as compared to the general population. Woe to the salesman who sold a guy an HT that breaks after a week!

I've had a guy threaten to kill me for refusing to return his money on a defective transceiver! If you take a radio in for service many times, you'll get incessant calls about its status until it's fixed, as if it'll get fixed faster while the serviceman is busy on the phone. So many hams go *berserk* when they don't have their daily radio fix, you wouldn't believe it!

You see guys come in, clamp a pair of headphones on and space out for hours listening to the Yamaguchi on display—without spending a dime. How many businesses would put up with that? If you politely tell them to leave, they get mad as heck. Hey, what can you otherwise do?

Finally, I ended up getting pretty darned disgusted with the technical ignorance of many hams of late. We had to wire dozens of mike plugs, even for Extra-class hams. As a salesman, you were expected to constantly give advice on how to hang antennas, read an swr bridge, or zero-beat a CW signal. That's fine to a certain extent, but so many wouldn't take the time to pick up an antenna manual to find out, even to maybe learn something. Why? If you are so damn lazy you memorized the Bash books to get your license, you're not about to read the ARRL antenna book to learn how to cut a dipole (which you should have known how to do in the first place). No, keep taking the easy way out and ask the radio shop guy.

So, after all this and more, a sincere guy or a beginning ham might come into a radio shop and just might get a little shortshrifted. Sorry, guys.

Name and address submitted

P.S. Please withhold my name from print. I might decide to go back into the ham business after all. (Where's my valium?)

By golly, you're not trying to tell us that you think that knowing the code isn't all that's needed? All these nerds who have been driving you crazy have passed the code test, so what are you beefing about? They may have an Extra-class license and be able to copy code at twenty per, but they can't wire a mike plug, eh? Well, that's what most hams want us to have, my friend, so stop beefing. Until I see some Bash books in shreds at ham stores I will continue to believe that most hams don't want anyone to know any theory . . . or how to build even the simplest of stuff . . . or to know one end of an antenna from the other. Your customer stories are the same as I'm hearing from all of the ham dealers. I've been pushing for a change from depending on the damned code to a real technical test, not a Bashed one. . . . with no noticeable success.—Wayne.

KEEP THE CODE

In response to your comments about having a no-code license, I was under the impression that amateur radio was developed "to provide a voluntary, non-commercial service that provides for emergency communications, the advancement of the state of radio art, and a trained pool of operators, technicians, and electronics experts (97.1.)"

Well, it seems to me that if we are to follow this rule we should go out of our way as licensed hams to help people become trained operators of CW. As you well know, CW can be heard when voice communications cannot be understood. Because of this, CW can be utilized much more efficiently during emergency situations.

I teach at the Virginia School for the Deaf and Blind in Staunton, Virginia. Two 14-year-old girls, both visually impaired, passed both parts of the Novice requirements this year and received their call letters (KB4AHA and KB4AGZ). For those who feel that the CW portion of the Novice exam is *too* hard, especially those who claim to be skilled enough to pass the technical portion of the Extra-class exam, I would like to have them talk to these two girls and the other 400-plus-thousand licensed hams across the United States.

In closing, if the no-code license is approved, the only people who will benefit are the 2-meter-rig manufacturers and those who don't really care enough about ham radio to take the time to learn one of the most important and useful aspects of amateur radio . . . CW.

William F. Bowman KA4UFI
Staunton VA

Well, Bill, what you say was true thirty years ago . . . maybe even twenty years ago. But you're so out of date with current technology that I don't know where to start. Apparently you are unaware of RTTY, which has been around for well over 30 years on the ham bands. You seem not to know about recent developments such as integrated circuits, digital electronics, and so on. Yes, in the days of spark, everything you've written was true. Alas, we still have a surprising number of hams who are living isolated in the old spark days.—Wayne.

PRICED OUT

These days, most countries, particularly Canada, have serious money problems, but even in our poor economic condition we haven't been reduced to the point where we have an official ½-cent coin.

I know the true value of our penny may not even be worth half of its face value, but it seemed very funny to me to see on the cover of your August, 1982, issue #263 that the price of the magazine was printed as $2.49½.

Either the proofreader missed it, or you have decided to print an error deliberately to see how many people really read it "from cover to cover."

ALSO THIS ISSUE!

R. Ian McAuley VE3MYO
Alexandria, Ontario

We have an opening for a new proofreader . . . any takers?—Wayne.

LAID OUT

Your new cover layout for the August issue of *73 Magazine* is great. Plus, I was glad to see that the articles were more in line with the *73* of a couple years ago. I was beginning to have my doubts about *73*, as the articles seemed to be getting away from ham radio somewhat. Having been a subscriber to *73* in excess of ten years, I hope the August issue is an indication of better ham radio articles to come.

Now, if you could just come out with a blockbuster RTTY issue like you did a couple of years back!

Vince Statlo WB2FYZ
Ilion NY

The September issue was packed with RTTY goodies, and let me make it perfectly clear (to coin a phrase) that I think that the future of hamming is tied in with digital communications . . . and that's RTTY. I want to publish articles on higher and higher-speed digital communications, on error-correcting code systems, on automatic relaying, and so on. If enough of us chip in (pun), perhaps we can set up some international relay system which will be of immense value in emergencies. We might even think about an organization which could be called the International Radio Relay League! The mind boggles. Anyway, glad you enjoyed the issue, and yes, we'll be having a lot more interesting construction projects.—Wayne.

NO THANKS

Just a short note to state that I have, over a period of 4 or 5 or 6 months, helped upwards of 50 hams and others through your "Ham Help" column (particularly on older receivers, transmitters, etc.).

Sad to say, only about 8 have even bothered to reply and thank me, or at least tell me to "get lost."

Kind of makes you wonder.

Roy H. Wilkinson
Bloomington MN

P.S. I have a much better "batting average" with the readers of Popular Electronics' "Operation Assist" column. Also, I miss your "want ads" column!

Roy, the place for your ham ads is in a ham ad paper, not a magazine. It takes about three months to print a ham ad in a magazine and by that time the stuff is usually sold. The ham ad papers get the ads out there in a couple weeks and do a nice job of it. I really hate to take bread out of the mouth of small entrepreneurs by competing with them in 73, so I urge all readers to use the specialty publications and keep them healthy. I wish that QST would do that, too. You'll note that we don't try to compete with CQ magazine and their specialized coverage of contests. Sure, there are only a couple thousand hams who are seriously interested in contests, but those who are should read and support the publication dedicated to them . . . which is CQ. I don't know what to say about the ungrateful cretins who get help and then say nothing.—Wayne

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

One of the questions raised a few months back regarding the design of a radioteletype receive program was how to make such a receiver immune to garbage or noisy signals. This month I'll take a look at one technique which can be used to overcome such a problem: multiple sampling.

Recall that each data pulse in a 60-wpm Murray character, of which there are five, lasts for 21 ms. Mechanical teleprinters do not use the entire pulse, but rather a small sample of it. Where this sample window is positioned depends upon the adjustment of the range selector. That is, only a small slice of each data pulse is read in order to determine whether that pulse is a mark or a space. Fig. 1 shows how this window overlaps the longer data pulse. Since mechanical printers time the "intra-pulse" interval from the position of the window on the data pulse, advancing the window toward the beginning of the pulse will enable the next pulse to be read that much sooner and can allow speeds slightly greater than 60 wpm to be read. It is by using this technique that so-called "66-speed" machines can be copied on an otherwise unmodified Model 15.

In an analogous fashion, simple RTTY receive programs such as those described here in the past sample each data pulse only once and use that information to reconstruct the Murray character. With the routines presented a few years ago, for example, a momentary sample from the middle of each pulse was obtained. A delay of 20 ms between samples kept the windows positioned near the middle of each data pulse.

The difficulty with such a scheme is that noise or fading can distort individual pulses within a character, thus changing the interpretation. A simple solution is to look at each pulse not just once, but several times, and base the decision of what to call that pulse on the sum of those samplings. Regular samples can be taken at, say, two-ms intervals to produce a time scheme such as shown in Fig. 2.

Having sampled each pulse many times and presuming we have stored that infor-

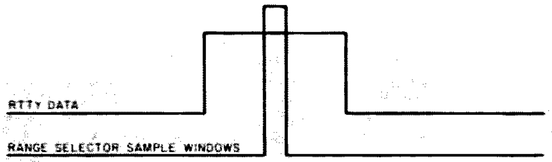

Fig. 1. The sample window.

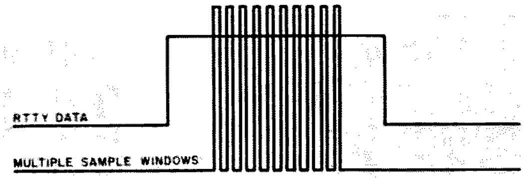

Fig. 2. Computer's multiple samples.

mation in some usable format, we must now decide what to do with that knowledge. Unless the circuit being monitored is an absolutely clear channel, it is doubtful that all ten (in this example) samples will be identical. In the case of pure noise, one might expect an average of half mark and half space, so a threshold would seem appropriate to adjudicate when to call a given pulse "mark," when "space," and when to throw it out. For want of a better suggestion, let's settle on seven or more samples one way or the other to label a state. Reading less than seven pulses of either mark or space will render the individual bit trash.

So you have a trash pulse, now what? It would seem that there are at least two ways to deal with that. Either you arbitrarily assign it as a mark or space and take your chances with the character, or you decide the entire character is lost and just loop out the time. The latter appeals to me the most; after all—garbage is garbage, no? In order to implement that, all you would need to do is keep track of how many bits you have read and delay whatever is left to get to the next stop bit.

I don't know how confusing that all is when you read it; it was not all that clear in the writing. I think that Fig. 3, a flowchart of what I am talking about, will help clear things up, though. The character reception routine is entered with a bit counter set at five, the number of pulses in a Murray character. After detection of a start pulse, additional counters for mark and space are set up and cleared. A loop is entered to sample each pulse ten times and register the state of the pulse sampled in the appropriate counter. After ten samples have been taken, the counters are examined to determine the probable identity of the pulse and record that in the correct position. Assuming all has gone well thus far, the sampling process is repeated for each of the five data bits, and the Murray character transmitted is recovered.

However, what if a bit is in error? What I have directed here is to trash the entire character. We do that by branching to a routine which waits out the remaining bits' time and then exits with a null for the received character. One presumes that the translation scheme used will ignore such a character.

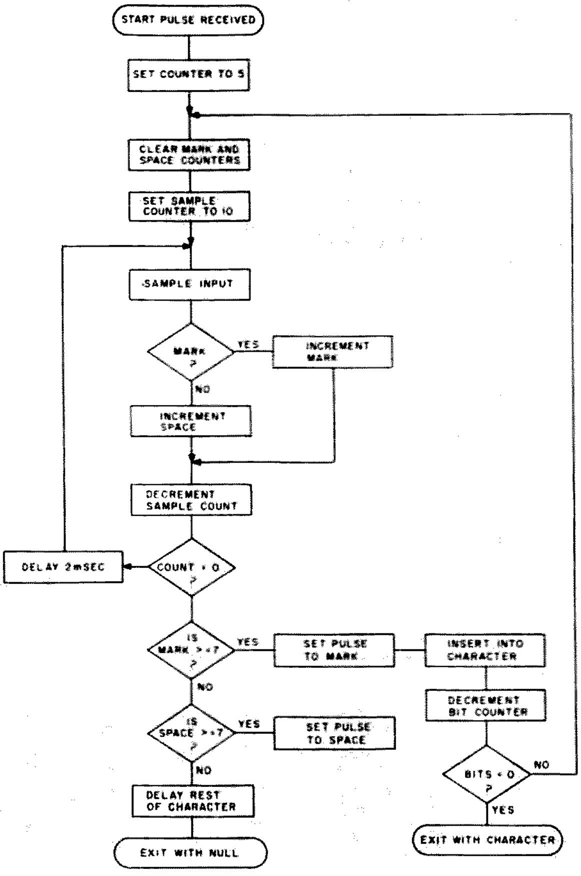

Fig. 3. Multiple sample flowchart.

This type of scheme is useful for eliminating erroneous characters where the error is generated between transmission and reception. For those errors generated on the operator side of the keyboard, you are on your own!

Turning to the mailbag, I have a note here from Leo F. McAuliffe, Jr., of Ashland, Massachusetts, who is a shortwave listener interested in copying RTTY. Leo is looking for a device which will display received RTTY on a TV screen, without having to invest a lot of money. Well, Leo, as you may have appreciated in the pages of ads here in *73*, there is not a lot on the market to do what you ask. Those units that are commercially available cost several hundreds of dollars, which you indicate is out of your range. I might suggest two possible alternatives. One would be to scout the hamfests in your area for an older, used, video RTTY unit, such as an old Microlog receiver. These were made some years back and should be turning up for reasonable prices on the flea-market circuit. Another idea is to put together a small unit yourself, using a dedicated computer, costing under $100, and an ASCII video display. Such displays may be old terminals or receive display boards, none of which should cost too much. For some time and elbow grease, you may be quite happy with what you will come up with. If there is sufficient interest, I would be willing to work out the design of such a unit. Let me know with, as they used to say on the tube, your cards and letters.

Among the new arrivals here at WA3AJR is another computer, an Atari 400. I bought it for the kids, but you know who is at the keyboard more and more. I am impressed by the programmability of this unit and hope that we will be able to use it on ham radio. I will keep my eyes open for applications, and I hope you do, too. I look forward to sharing with you whatever we all can discover in future columns.

Next month, some more investigations into the design of the ideal RTTY terminal program, as well as a look at what some of you are saying. Winter is a great time to work in the shack, even though these new transistorized/ICized rigs don't put out the heat of a pair of 807s. Let's see what kind of things we can do in next month's RTTY Loop.

DX

Chod Harris VP2ML
Box 4881
Santa Rosa CA 95402

THE TOP TEN

What are the Top Ten? No, not the best selling rock-and-roll records, but the most sought-after countries in the DX world. Every year *The DX Bulletin* surveys the top DXers in this country and other countries to determine which countries are most needed. *The DX Bulletin* concentrates on those DXers with more than 250 countries worked and is the most prestigious of all the bulletins. Its Top 73 list is the most complete and well-respected of any such list in the world. Some amateur radio manufacturers determine who will receive DXpedition rigs on the basis of this survey. *The DX Bulletin* recently granted permission for this column to reproduce the 1982 list of the most needed countries. Here is the list, with comments on future amateur radio activity. (For further information on *The DX Bulletin*, write 306 Vernon Avenue, Vernon, Connecticut 06066.)

1. *China BY.* China tops everyone's most wanted list, with almost no legal amateur radio since the early 1950s. But that is changing (see this column, July). More BY stations are coming on the air, and BY will move down the most wanted list in future years. Not rapidly, but it will slowly move down until everyone has worked BY.

2. *VK/Heard.* This tiny rock near Antarctica will host one or two major DXpeditions in 1983. Watch Heard drop completely off the most wanted list next year.

3. *VU/Laccadives.* The only island worth landing on in this archipelago is the base of considerable pirate activity. No, not radio pirates, but real life pirates who don't leave live victims. No one in his right mind goes anywhere near the Laccadives.

4. *Albania ZA.* It's the political climate that keeps amateur radio out of Albania. As one of the poorest of the Eastern European countries and one close to the Soviets, Albania has taken a dim view of ham radio for years. There are signs of a softening of this attitude, however, and rumors continue to fly of a DXpedition to Albania any day now. Don't hold your breath, but don't hesitate to work any ZA you might hear.

5. *Cambodia XU.* Political turmoil and civil war preclude ham radio from Cambodia. Official permission is unlikely in the near future; we'll just have to wait until things calm down.

6. *South Yemen 7O.* A similar case to Albania. South Yemen is in the Soviet camp, and they don't endorse amateur radio.

7. *Bouvet 3Y.* Another tiny island near Antarctica, Bouvet sees occasional tourist and scientific traffic. Permission from Norway can be obtained, and Bouvet might well be a target of a DXpedition soon, but probably not this winter.

8. *Andamans VU.* At least one amateur is listed as having a license for the Andamans, but activity has been non-existent. The Indian rules prevent outside amateurs from getting licenses, and the locals don't seem to show enough interest in activating one of the rarest of all DXCC countries.

9. *Burma XZ.* The official Burmese government says "No" to any amateur radio, and the ARRL refuses to accept the operations from the "rebel" north half of the

A gaggle of FO8s. Did you work 3 FO8 stations on two different bands during their Tiurai celebration July 14-22? If so, you qualify for a special award, but you must request the award before the end of the year. 15 active FO8s made more than 5000 QSOs during the celebration. (FO8GM photo courtesy of WB6GFJ.)

country. This political mess shows no signs of being straightened out in the foreseeable future.

10. *San Felix CE0X.* Getting a license is trivial (I have one), but getting onto the island is impossible. The entire island is a military base (like Aves in the Caribbean) and "gringoes" are not welcome. Even the Chileans have been unable to convince the military higher-ups that they mean no harm in their planned DXpedition. A recent "operation" from San Felix turned into a fiasco when the Chileans claimed the operator was nowhere near the island at the time. This could break at any time, but I rate it doubtful.

The main difference in this list from a similar one twenty years ago is in the reasons for lack of activity from a country. Twenty years ago the reasons were physical inaccessibility and lack of transportation and accommodations in the country. It's hard to mount a DXpedition when you have to pack your gear, generators, and fuel in on camels. The transportation picture has changed for the better, and no spot on this earth is out of reach of a determined amateur.

But the political realities have changed for the worse. Certain cheats and frauds in the last 20 years and increasing sensitivity to feelings in developing countries have led to a more formal approach to the documentation needed for a DXpedition to "count" for DXCC. The conservative attitude of the ARRL DXCC staff means an amateur cannot simply operate from a country; he must be welcomed by that country and operate with their full cooperation. This is simply impossible in many countries. Many emerging countries are reluctant to put *anything* down in writing, although they are eager to give verbal permission to operate.

Another reason for the reluctance of countries to permit even visiting amateurs to operate is the fear of spying, internal revolt, or outside takeover, all of which require radio communications. Unsophisticated customs officials cannot differentiate between spy gear and a TS-830. (On second thought, are there any real differences?) So it is simpler always to say "No" than to see if it is possible to say "Yes." We probably won't see this attitude change quickly. Only patient demonstrations and years of support, documentation, and assistance will win jittery governments over to the value of amateur radio, as we see happening in China.

What does this mean for the DXer? If you want to get on the Honor Roll (having worked almost all the DXCC countries), you must have patience. It may be many years before we see significant radio operations from many of the Top Ten.

If you do hear one of these highly desired countries on the air and are fortunate enough to work it, the battle is only half over. Now you have to get a QSL card to prove you worked him.

QSLS AND QSLING

There is more to DXing than working the DX station; getting the confirmation of the contact can be every bit as challenging as breaking through the pileup. But a few hints and suggestions can substantially improve your QSL percentage and get some of those coveted pasteboards "on the wall."

In this first part of this series on QSLing we will consider the card itself: the selection, design, and printing of your own QSL card. In future columns we will advise how to fill out the card, how to get the card to the appropriate place, and QSL bureaus.

Your Personal QSL Card

There are no rules requiring that acknowledgement of a DX contact must be in the form of a postcard-sized paper. QSL means acknowledgement of a contact, not a special card. But *everyone* who seeks those acknowledgements uses the universally accepted QSL card. In more than 100,000 requests for my QSLs, I have *never* received a request without such a card. Only a tiny handful have been other than postcard-sized. So while there are no formal requirements for the dimensions of the QSL, I recommend sticking to the standard format.

Choosing Your Card

Given the transient nature of most DX QSOs, the DX station has little opportunity to get to know you. If the QSLing is handled by a QSL manager, the person filling out your return card will know even less about you. So your QSL card reflects your personality and amateur radio interests even more than your DX contact.

When the time comes to choose your QSL card, you first have to decide on a custom card or an off-the-shelf commercial card. There are dozens of commercial QSL card printers. Most offer a set of samples and designs for a nominal fee. Once upon a time the QSL printers would obtain the FCC list of new licensees and send you a set of samples and order forms before you even received your license! You were so pleased to learn your callsign that you immediately ordered 1000 of their fanciest cards. 950 of these are probably still gathering dust in your basement.

The advantages of commercial QSL printers are many. They produce a good looking card at relatively small expense. The card is easily recognizable as a QSL and it is printed on stock heavy enough to go through the mail as a postcard. Prices range upward from a few cents a card. You can select from a bewildering variety of cards, including multi-colored cards, two-sided cards, and more. Ordering your commercial QSLs is trivial: You pick your design, fill in the blanks on the form, and send in your money. You will get your cards back in a few weeks—longer if you use one of the smaller printers.

But for DXing, standard QSL designs have one major disadvantage: They are all the same. No, not identical, but an active DX station who receives thousands of QSLs each year will have seen dozens or hundreds of similar cards. Your card will be one of the pack; it won't stand out. Some hams try to make their cards stand out by using bright orange QSLs that glow in the dark. I still see spots before my eyes from opening an envelope with one of these Day-Glo orange QSLs. But I have received bunches of these, too. Certain QSL designs are so popular that I have received hundreds of cards identical except for the callsign. Needless to say, I am not intrigued to receive yet another one of the same design.

This doesn't mean that standard design QSLs end up in the circular file. It just means that they get answered just like any other QSL, no faster or slower. The call and the individual operator will not be remembered any length of time.

The cards (and operators) who do stick in the mind after the QSL is answered are those personal cards, cards which say something about the ham and his station.

If you do decide on a commercially-produced, standard QSL card, there are a few things to keep in mind when making your selection. First, avoid commercially-produced two-sided cards. These are the cards with the personal information on one side (callsign, name, and address) and a standard QSL form on the reverse. Why avoid these? The DX station must first find your QSO in his log. This means comparing the time of the QSO on the back of the card and the callsign on the front with his pages and pages of log. Sometimes the card must be flipped several times before the QSO is located in the log. Then, in order to fill out the return card, the DX operator must first record the QSO information and then turn the card over to get the callsign. Big deal, you say. How difficult is it to turn the card over? Flipping one or two or ten or a hundred cards is no big deal. But when you deal with thousands and thousands of cards, the QSLer soon learns to dread the sight of another two-sided card.

Two-sided cards also lead to possible errors on your return QSL. In the process of flipping the card, the DX station might forget the call, or transpose two letters, etc. The result might be a QSL card which will be rejected by the DXCC checkers.

This does not mean that all two-sided QSL cards are useless for DX purposes. There is nothing wrong with a card which has the call and name on one side and the QSO information on the reverse, *as long as the callsign also appears on the reverse.* Then the DX station (or QSL manager) doesn't have to flip the card; the callsign is right there on the reverse with the QSO information. But few commercially-available two-sided cards offer this option. It requires custom printing of *both* sides of the card, greatly increasing the costs, and eliminating many of the economies of scale of QSL printing. So if you intend to do a lot of DXing, stick with single-sided QSL cards.

Another thing to check when you purchase commercial cards is the glossy finish. Many of these very handsome and attractive finishes will not absorb ink from felt tip pens. The ink puddles up and smudges off. Hard pencils may make a very light trace on some coated cards. Test your sample cards with your usual writing utensil. Does the pen make a clear, clean impression which doesn't smear? Not all shiny cards have this problem; you have to check the sample.

Another possible problem with commercial QSLs is the use of strange typefaces. Some amateurs choose an exotic typeface for their callsign and address, one that is different, on the hope that it will make their standard card more distinctive. Don't! These weird typefaces are often difficult to read. Typefaces that look like script or brush strokes are especially difficult to read. What difference does it make, you ask? If your callsign is difficult to read, the DX station might get it wrong. Then he might not find it in the log, or he might fill out your QSL to someone else's call! For the same reason avoid those ubiquitous silver-on-black QSLs. They are very difficult to read!

Custom QSLs

I personally prefer custom-designed QSLs, both to send and to receive. I feel the QSL card is an extension of your amateur radio personality, and it should say something about you and your *amateur* career. Custom-designed QSLs need not be elaborate or expensive, and the initial effort quickly pays off in improved returns.

What should go onto your personal QSL? Make sure you have the basic information: your callsign, name, and address including county. You will also need blanks for the QSO information. If you work one mode or band predominantly, you might want to customize the QSO information. For example, a 20-meter enthusiast might have "Freq. 14 _______MHz." Be sure to say that this card is a confirmation of the QSO described; many commercial cards omit this vital line.

I have used both the box format and a sentence format for the QSO information, and I definitely recommend the former. The sentence format (i.e., "This confirms our 2X_____QSO on _____ on _____MHz at_____UTC, with your signals _____ RST.") is cumbersome and very prone to error. The box format is clean and easy to fill in and read. Amateurs seem to be able to make the simplest task complicated and so produce a bewildering number of combinations of these QSO information boxes. For consistency and to assist the person filling out the return card, I suggest the following format: Callsign, Date, UTC, MHz (not band), 2X(mode), RST. If you are designing your own card from scratch, be sure to leave enough space in each of the boxes for the required information. In other words, the boxes for the callsign and date should be substantially larger than those for the other information. Better yet, take a blank QSL with well-designed boxes and steal the format.

Another important item to include on your custom QSL is a request for the DX station's card. You would be amazed at the number of QSLs I have received without such a request. Since I receive and

send thousands of cards each year, I do not answer cards that don't have a specific request for my card; I assume the card is an answer to a card I sent. By the way, avoid those cute QSLs with the QSO information hidden on a drawing of a rig, etc. Anything that makes the QSO information hard to find or decipher will slow up your return card.

So much for the nuts and bolts of OSL card design. What about the overall look? What personal information will customize your OSL? A photograph of yourself at your operating position with QSLs and awards in the background says more about you than any amount of text. A good photograph shows your equipment, station layout, your most prized awards, and (very important) adds a face to your call. My favorite QSLs to receive are definitely photographic QSLs, because they say so much about the operator without listing hundreds of awards no one has ever heard of.

The major drawback to a photographic OSL is the considerable initial expense. But if you can find a friend who will take a good black-and-white photograph, you can save a good part of the cost. There is usually at least one good photographer in every radio club.

What about listing your equipment and antennas on the OSL? Every time I have done this, I have changed the gear as soon as the cards come back from the printer. If you trade your equipment regularly and try new antennas every season, you should leave the listing of gear off the card. If you are satisfied with your Collins gear and Big Bertha, by all means list the equipment; the DX station is always interested in knowing what produced that strong signal.

Once your card is designed, there remains the choice of how to print it. Some of the QSL printers will produce a custom card from your sketch, but expect to pay for their services. I prefer the quick-print approach, as I usually print many thousands of cards at a time, and the quick-print shops will produce a card for less than a penny apiece. I provide camera-ready copy and the printer prints four cards on each sheet of paper and cuts them into QSL-sized cards. (Postal Service requirements insist on a certain minimum size for postcards; check this before you have the cards trimmed. Also make sure your card will fit into a standard small envelope without folding.)

Whatever format or type of OSL card you select, you still have to fill it out properly, get it to the correct individual, and get his card back. We'll discuss these other steps on QSLing in future months.

AWARDS

GLADESPEDITION

The Fort Myers Amateur Radio Club will be conducting a "Gladespedition" to Glades County, Florida. Operations will begin on November 13, 1982. W4LX will be operating in the General bands, both CW and SSB. Some Novice contacts will also be made. If you need Glades County, be sure to look for them. QSL to: David Fox KA8CXQ, PO Box 051131, Tice FL 33905. SASE please.

45th PARALLEL

The Tri-County Wireless group will mini-DX from Gaylord, Michigan, on the 45th parallel (halfway between the equator and the north pole) from 1400Z November 13 through 0600 November 14. Phone only at 3.925, 7.250, 14.300, 21.375, and 28.550. Certificate for QSL and SASE to N8COY.

ABC-TV

The ABC-TV Washington Engineering Group, celebrating the first year of operation from the network's new Washington news bureau, will be on the air Saturday, November 13, from 1400Z to 2200Z, on SSB frequencies (plus or minus 5 kHz): 7.245 and 14.285 and on CW for Novice and Technician contacts on 7.125 (listening at 45 minutes past each hour). KB7ZZ/3 will also be on 145.190 FM (W3DOS/R) throughout the operation period. Special events QSLs via business-size SASE to: Steve Malis KA4ORL, 2520 Heathcliff Lane, Reston VA 20091.

JERSEY DEVIL STATION

The West Jersey Radio Amateurs (WJRA) will mount a second operation from the South Jersey Pine Barrens, the haunt of the feared Jersey Devil. Beginning and ending at midnight, the courageous WJRA group will attempt again this year to operate the entire 24 hours of Halloween, October 31st. A unique, handsome certificate engraved with a countenance of the Jersey Devil will be sent to all stations worked who send an SASE to WJRA, PO Box 62, Burlington NJ 08016. Frequencies to be used are 15 kHz from the bottom of each General phone band, 80 through 2 meters, and 146.55 FM. Novice operation will also be 15 kHz up.

The Jersey Devil was born in 1735, a 13th child, in the Pine Barrens of Burlington County at a place called Leeds Point. Not long after its birth, on a foggy and dreary night so usual in the Pine Barrens, the child assumed a serpent-like body, cloven hoofs, the head of a horse, wings of a bat, and the forked tail of a dragon. With loud raucous cries, it flew up the chimney and into the heart of the Pinelands. Appearances and sightings occur even today. On Halloween, the WJRA will maintain a radio vigil, trying once again to capture a glimpse of the Devil. Will they see him? Give them a call—W2JUG—and get a first-hand report.

Table 1. AMSAT nets provide up-to-the-minute news about amateur satellite developments.

AMSAT NETS

Keeping up with the latest developments in the amateur space program is as easy as tuning your ham rig to one of the AMSAT nets. During these sessions, you'll hear information ranging from the latest Phase III news to tips on when and where to work the rare satellite DX. Technical discussions abound, and you can usually pick up the latest tracking data. Table 1 is a list of these informative gatherings.

PHASE IIIB PROGRESS

Summer was a time of further testing and refinement for the Phase IIIB satellite, now tentatively scheduled for January, 1983,

launch. According to the *AMSAT Satellite Report*, malfunctions which occurred in both communications transponders during a midsummer thermal/vacuum test were quickly corrected by the AMSAT DL crew in Germany.

If all goes as planned, Phase IIIB will fly aboard the seventh launch (L7) of the European Space Agency (ESA) Ariane missile. The January launch date depends to a large extent on the successful launches of L5 and L6. The former was scheduled for early September and the latter for late November.

ESA's Ariane is now a head-on competitor with the Space Shuttle as a commercial satellite launcher. By means of low prices, advertisements in satellite industry magazines, and other marketing tools, ESA has built a backlog of more than 20 spacecraft awaiting a boost into orbit.

NEW — REVOLUTIONARY MULTI—MODE & CRYPTO—DECODER

NOW FOR THE FIRST TIME—PRINT THOSE UNPRINTABLE SIGNALS

• BIT INVERSION • TOR—SITOR • NON STANDARD SHIFT • WEATHER FORMAT

• PLUS ALL SPEEDS AND SHIFTS OF BAUDOT, ASCII, AND CW—AMTOR WHEN ARRPOVED.

FEATURES:

ASCII 110, 150, 300, 600, and 1200 BAUD rates.

BAUTDOT 60, 66, 75, 100, and 132 WPM

MORSE CW—AUTO—RANGE Up to 60 WPM

TOR—SITOR Both ARQ and FEC modes with full receive only function on these codes. AMTOR when approved.

BIT INVERSION 5 level security BIT inversion for BAUDOT deccding from key pad. Decodes any combination of BIT inversion being used for security.

3 SEL CALLS Factory programmed - for amateur or RTTY listening Displays actual SEL CALL on screen.

2 VIDEO FONTS Weather box and standard ASCII font

SPEED READOUT ASCII & BAUDOT - Automatic search gives speed of transmission.

VIDEO OUTPUTS Composite video 1.5. V P - P negative sync, four formats.

PRINTER DRIVER Isolated Loop MIL -188 or RS -232 and optional parallel ASCII. All with handshaking available.

LOOP SUPPLY 60 MA/20/ MA auto adjusting loop supply available as option.

OTHER FEATURES Front panel indicators, rear panel jacks, status line, multiple scroll inhibit, and un-shift on space.

NEW PRODUCTS

GaAsFET VHF/UHF AMPLIFIERS

Lunar has announced a line of narrowband tuned receiving preamplifiers for the VHF and UHF communities. Typical specifications exceed those of previously-available receiving preamplifiers by up to ten times in performance. Exhibiting very high gain at VHF (typically 22–24 dB), moderate gain at UHF (typ. 16 dB), and a very low noise figure (typ. 0.3–0.4 dB on VHF and 0.5–0.6 dB on UHF land-mobile frequencies), these units are also well-suited to high-rf environments, exhibiting 1-dB compression power levels of + 10 dBm or more.

The good gain, coupled with the very low noise figure, effectively reduces a typical repeater receiver sensitivity to that of ambient limitations. 6–10-dB improvements in receiver performance have been consistently reported by users in a typical repeater installation between the duplexer and receiver input.

Units are built to the customer's specified frequency, but do exhibit a typical bandwidth of 5% CF with little degradation in performance. Dc input is well-filtered and regulated, which allows accepting any dc voltage between 12 and 28 V (drain approx. 35 mA). VHF connector options include BNC, SMA, N in and out; UHF connector options are SMA, N in and out, with SMA in BNC out the standard option. SMA to RG-58 connectors are included as options for UHF units. Frequencies are available from as low as 15 MHz to as high as the 800-MHz land-mobile bands.

For further information, contact *Lunar Electronics, 2775 Kurtz Street, Suite 11, San Diego CA 92110.* Reader Service number 484.

NEW FROM W-S ENGINEERING

W-S Engineering, manufacturers of the Porta-Peater, have announced the introduction of new related products that will be of interest to both Porta-Peater owners and other amateurs alike.

In addition to the Porta-Peater M-100, which will interface with any two transceivers or receiver and transmitter pairs to create a full-function repeater, W-S Engineering now offers its new Porta-Link PL-250 and MB-1 Multi-Board building block.

The Porta-Link PL-250 is a single-board simplex link and portable repeater that may be interfaced with two transceivers, or two receiver-transmitter pairs, to form a complete repeater system for applications that do not require a CW-ID system. Owners of the Porta-Peater can add the Porta-Link board and have a complete duplex link, remote base, and dual repeater. The PL-250 has on-board controls for timeout duration, hang time, audio balance, local mike gain, and local speaker amplifier gain. Connections to the PL-250 are done via a 22-pin, 0.156-inch edge connector.

The MB-1 Multi-Board building block is a "universal" circuit that can provide up to *ten* different functions. Configured by the user, the MB-1 can be a variable audio-frequency signal generator, variable radio-frequency signal generator, audible CMOS logic probe, LED output logic probe, repeater beeper, gated monostable, gated astable, pulse stretcher, adjustable timer, individual positive and negative edge triggers, and more.

The MB-1 is completely self-contained and operates on any dc voltage between 5 and 15 volts. Output level, pulse length, and frequency are fully adjustable with on-board controls. The MB-1 comes complete with an assembly and applications manual, and all parts, sockets, PC board, and accessories are furnished.

For further information about these products, contact *W-S Engineering, PO Box 58, Pine Hill NJ 08021.* Reader Service number 481.

YAESU FT-102

Yaesu Electronics Corporation has announced the availability of its new FT-102 line of HF equipment.

The FT-102 transceiver utilizes an all-new transmitter section featuring three 6146B final tubes for extremely low distortion. In addition to VOX and an rf clipping-type speech processor, the FT-102 transmit audio may be adjusted for optimum response to the operator's voice.

The FT-102 receiver uses husky JFET components in the front end for wide dynamic range. A number of filter options are available, with wide/narrow filter selection independent of the mode switch. Audio peak filtering for CW, audio shaping for all modes, and an i-f notch filter provide outstanding intelligence recovery. The noise blanker is highly effective against the "woodpecker" and pulse noises.

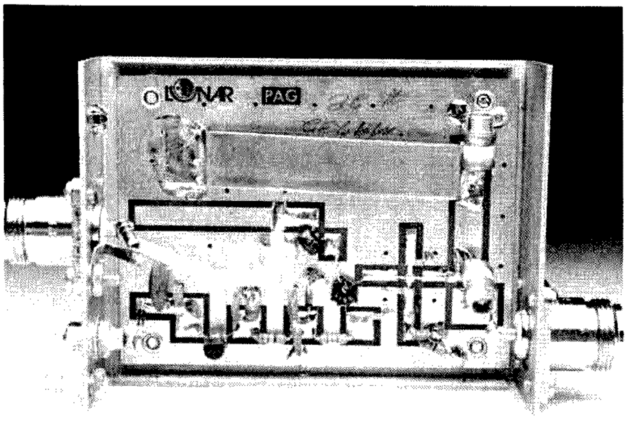
Equipped for SSB and CW operation, the FT-102 option list includes an AM/FM module for activating those modes. Other accessories for the FT-102 are the FV-102DM synthesized vfo, the SP-102 speaker with audio filter, the SP-102P speaker/patch, and the FC-102 1.2-kW antenna tuner with optional remote antenna selector.

For further information, contact *Yaesu Electronics Corp., PO Box 49, Paramount CA 90723.* Reader Service number 476.

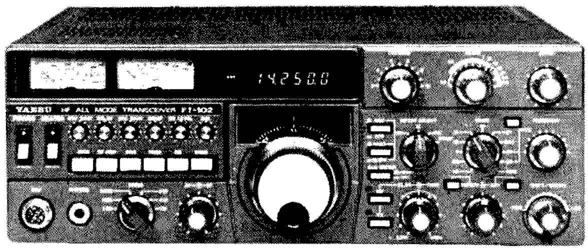
DENTRON'S NEW 5-BAND TRANSCEIVER

DenTron Radio Company has begun production on a new 200-Watt, CW, SSB solid-state transceiver named the Horizon One, which covers 80-15 meters and any 500-kHz segment of 10 meters. Its sensitivity is .35 uV for 10-dB signal-to-noise ratio, with selectivity of 2.4 kHz at 6-dB points and G-60-dB factor of 1.7:1. Performing with the latest MOSFET and ballasted emitter semiconductors, the Horizon One also has a pinpoint digital frequency readout using LSI technology.

Input power is 200 W PEP with an output of 100 W PEP nominal and 80 W PEP on 10 meters. Power requirements are 12.6–14.5 V dc regulated at 2.0 Amps maximum and 12.6–14.0 V dc regulated or unregulated at 18 Amps peak. The Horizon One has a built-in VOX, noise blanker, and hand mike as standard

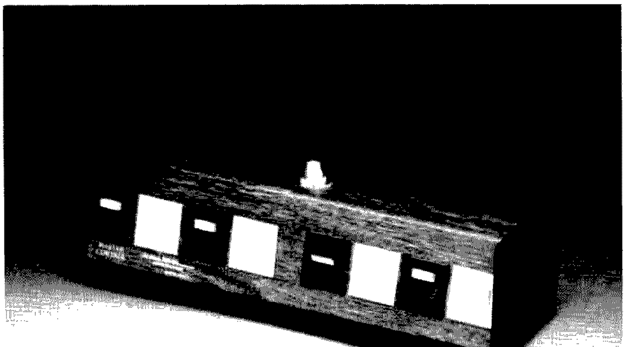


Lunar's GaAsFET VHF/UHF amplifier.



Yaesu's FT-102.

DenTron's Horizon One.



Alpha Delta's Master Control Console.

equipment. Optional accessories include an ac power supply, matching antenna tuner, linear amplifier, and mobile mount.

For further information, contact Tim Neill, Technical Sales Representative, *DenTron Radio Company, Inc., 1605 Commerce Drive, Stow OH 44224; (216)-688-4973.* Reader Service number 485.

DIVERSITY RECEPTION FOR REPEATERS

Pegasus Electronics has announced a new diversity receiving system for repeaters. Now you can turn any repeater into a "super repeater" by adding a VS-2 voting system and an rf link. The VS-2 compares the audio quality of any 2 receivers (they need not be matched) and connects the one that hears you best to the repeater for retransmission. Since the VS-2 is always listening to both receivers, it can continuously update as you go from a peak on one to a null on the other. The result: You have a repeater which sounds like it has no "dead" spots and your users are always readable as long as they are solid Into any *one* of your receivers.

The VS-2 was designed to work with anything. It has all its own level controls and ensures a constant output to your repeater. It was designed to be installed by anyone who knows how to read a scope. The VS-2 is supplied on a single circuit board (5⅛" × 5¼") and contains two squelch circuits (COS). It is fully compatible with 12-volt logic, 5-volt logic, and inverted logic by cutting the desired jumpers (or you can use your own logic and bypass that portion of the VS-2). The VS-2 is not a kit—it comes fully assembled and tested and is warranteed for one full year.

For further information, contact *Pegasus Electronics, Inc., 88 New Dorp Plaza, Staten Island NY 10306.* Reader Service number 488.

PHOTOVOLTAIC SYSTEMS

Encon Corporation, authorized distributors of Solarex photovoltaic products, has a publication entitled *The Complete Photovoltaic Systems Catalog* which can answer many of your questions about solar energy conversion and distribution. The catalog covers an introduction to photovoltaic systems, photovoltaic cells and panels, renewable energy batteries, charge controllers and metering devices, ac power inverters, how to select a workable system for your needs, basic 12-volt systems, large-dc/small-ac systems, components and accessories you will need, solar demonstrators, educational materials, marine and recreational panels, and much more.

If you have an interest in direct conversion of sunlight to power, you will enjoy this catalog and overview of the entire subject. A price guide as well as an applications questionnaire form are included so that you can obtain expert advice and assistance for potential applications that you may have in mind. Encon will assist you with your questions and needs in solar applications.

For further information, contact *Encon Corporation, 27584 Schoolcraft, Livonia MI 48150.* Reader Service number 479.

MASTER CONTROL CONSOLE

Alpha Delta Communications has just announced its new Master Ac Control Console which combines power-surge protection and centralized "on/off" control of several components. The MACC unit plugs into a single outlet and provides eight plug-in "U" ground outlets: one "hot" outlet for continuously-powered appliances such as a clock, for example, and seven outlets for individually-controllable components.

The front panel has rocker switches for the individually-controllable components, plus a master control "on/off" rocker which allows the entire system to be turned on or off at once. All rockers are lighted when "on."

The surge-protection feature is perhaps the most important feature of Alpha Delta's MACC unit. The delicate circuitry of modern solid-state electronic equipment is particularly vulnerable to damage from power surges and spikes which can be caused by natural or man-made sources such as lightning strikes, electric motors, transformers, wind-blown snow, clouds, fluorescent lamps, power outages, and the like. The MACC is tested to IEEE pulse standards and is rated at 15 A, 125 V ac, 60 Hz, 1875 Watts continuous-duty total for the console.

Priced at $79.95 (US), the MACC is available from Alpha Delta dealers or, for $4 more to cover postage and handling, direct from the factory. Alpha Delta will quote on overseas postage and on the "European Model" MACC-E available with VDE-approved socket for 240 V ac.

For further information, contact *Alpha Delta Communications, PO Box 571, Centerville OH 45459.* Reader Service number 486.

MORTTY SOFTWARE FOR COMMUNICATIONS

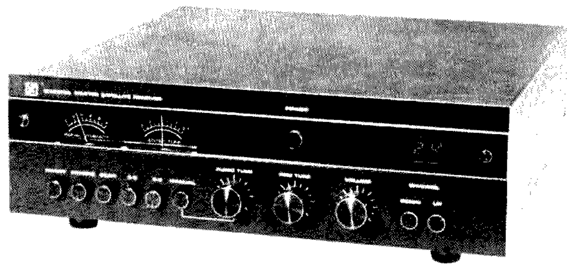
MORTTY is a general-purpose communications program adaptable to almost any set of conventions in current use. It includes ASCII and Baudot capabilities at a wide range of baud rates. There are 18 parameters for adaptation to particular conventions such as full screen, split screen, full or half duplex, and many more. There are 15 disk operations, including disk file send, receive, direct binary to hex upload, hex to binary download, automatic message capture with file sequencing, and automatic answering of messages from a disk file.

The equipment required to make use of the program is an H89 or Z89 microcomputer with 32K of memory and an H88-3 serial interface. MORTTY reprograms the serial interface for baud rate, etc., according to the communications mode selected, and does the translation between ASCII and Baudot when a Baudot mode is in use. In place of the H89 or Z89 with H88-3, you may use an H8 with H19 terminal and H8-4 serial interface with H17 disk system.

The software required is HDOS v. 2.0, which is the current Heath disk operating system. Heath claims that programs should be upward-compatible with new HDOS releases, but we cannot guarantee that this will always be true.

The price of the MORTTY pro-

MFJ's VHF converter.



Channel Master's model 6128 satellite receiver.

gram is $100.00 ppd in the USA. Ohio purchasers should add 6% sales tax. Foreign prices will depend on the additional expenses of mailing. This price buys a printed copy of a thorough user's guide of about 60 pages and a 5¼" hard-sector disk with the absolute binary MORTTY program.

For further information, write *"MORTTY program"* or *"Phillip L. Emerson" at 3707 Blanche, Cleveland Heights OH 44118.* Reader Service number 480.

MFJ-313 POLICE/FIRE/ WEATHER BAND CONVERTER FOR 2-METER HAND-HELDS

MFJ has introduced its new compact VHF police/fire/weather band converter for 2-meter hand-helds.

It turns your synthesized 144-148-MHz hand-held into a police/fire receiver (154-158 MHz) and gives you direct frequency readout on your hand-held. A programmable scanning hand-held becomes a sensitive programmable police/fire scanner.

You can also receive weather, maritime coastal, and more on the 160-164-MHz band. Feed-through allows simultaneous scanning of both 2 meters and the 160-164-MHz band.

A high-pass input filter and a 2.5-GHz transistor give very high uniform sensitivity over both the 154-158-MHz and 160-164-MHz bands. Each band is crystal-controlled for excellent stability.

A Bypass/Off position allows transmitting through the converter. It is protected against burnout if you transmit (up to 5 Watts) with the converter on. Short direct-signal paths give low insertion swr.

This compact converter measures only 2¼ × 1½ × 1½ inches and weighs 4 ounces. A single AAA battery (not included) gives you months of operation. The cabinet is black and is made of rugged, lightweight aluminum for years of hard use. BNC connectors mount the converter directly between your handie-talkie and antenna without cables.

For further information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 483.

NEW FROM VOCOM

VoCom Products Corporation has announced two new products for the amateur 220-MHz band: a "two Watts in, twenty Watts out" power amplifier with a suggested list price of $84.95 and a "Power Pocket" for the Icom IC-3AT hand-held transceiver with a suggested list price of $229.95.

With the Power Pocket, the 220-MHz operator now has the same advantage that he had on two meters: the convenience of a hand-held and the punch of a mobile rig. Styled essentially the same as the two-meter version, the 220-MHz Power Pocket offers a large speaker, an audio amplifier, an rf power amplifier, and a battery charger that meets the current requirements of the radio. For example, you can use the amplified hand-held in your car on the way to work, hold your own in any QSO, and arrive with a battery that is still charged...as good or better than it was when you started!

For further information, contact *VoCom Products Corporation, 65 East Palatine Road, Prospect Heights IL 60070.* Reader Service number 478.

EARTH-STATION RECEIVER

Channel Master has just introduced a new Earth-station receiver, the model 6128, offering a wide range of features and advanced electronics. The receiver is a 24-channel synthesized unit employing a single downconverter installed at the dish and a receiver unit located in the home.

For simplified tuning, the full 24-channel number format is displayed on the receiver's LED digital channel display. Channels are power-selected by Up/Down push-buttons and fine tuning is provided with the assistance of the Center/Fine Tune meter.

Two Priority Audio buttons select audio channels (6.8 and 6.2 MHz), while additional audio channels may be selected manually.

A signal-strength meter shows the relative strength of received signals. The Channel Scan button is depressed to cycle the receiver through the complete horizontal channel range in about one second, as an aid to aiming the antenna.

Automatic polarity switching allows one-button selection of any channel without additional polarity adjustments, and a built-in modulator eliminates the need for a separate modulator. The model 6128 is capable of receiving normal or inverted video signals. An optional model 6192 remote control unit offers the added convenience of remote channel selection and fine tuning.

For further information, contact *Channel Master, Division of Avnet, Inc., Ellenville NY 12428.* Reader Service number 482.

NEW TS-830, TS-930, R-820 FILTER KIT

Fox Tango Corporation has announced the availability of a special high-quality matched-filter kit designed to significantly improve the selectivity of the popular Kenwood R-820, TS-830, and new TS-930 series. These rigs all use similar dual-conversion i-f systems with 8830-kHz first and 455-kHz second intermediate frequencies. I-f bandwidth filtering at both frequencies is used to provide VBT (variable bandwidth tuning). However, in the TS-830S model, the 2.7-kHz bandwidth of both original filters (resulting in a net bandwidth of 2.4 kHz with VBT off), the combined filter shape

factors (1.34 with VBT off), and a combined ultimate rejection of about 80 dB leave much to be desired.

Under the same conditions, the Fox Tango filters (both 8-pole discrete crystal units instead of the original monolithic and ceramic types) each have a bandwidth of 2.1 kHz (net bandwidth of 1.99 kHz), a combined shape factor of 1.19 (the lower, the better), and an ultimate rejection greater than 110 dB (the higher, the better). The effects are even more pronounced when VBT is used to narrow the operating i-f bandwidth to reduce QRM.

The matched-pair filter kit, complete with detailed instructions, two 2.1-kHz Fox Tango filters (guaranteed for one year), and all needed cables and parts, is being offered at an introductory price of $150 plus $3 for shipping ($5 for air).

For further information, contact *Fox Tango Corporation, PO Box 15944, W. Palm Beach FL 33406; (305)-683-9587.* Reader Service number 477.

REVIEW

COM-RAD INDUSTRIES CR1720A "MOBILE EAR" ANTENNAS

Jim Waldron of Com-Rad has been interested in space-saving antennas for a long time, and he has built and tested dozens of them with the idea that a better antenna can be built and is much needed. Jim's idea of a "better" antenna is one that is small, compared with a full-size antenna for the band selected; one that is rugged and has a low profile; one that is easy to tune; and one that is duck soup for mobile operation, yet may be used in portable or fixed operation as well.

At first glance, the Mobile Ears look something like a cross between a giant coil and a short dipole, and that is almost exactly what they are. The large-diameter helix is resonated to frequency by the capacitance-to-ground of the adjustable "resonator"—a capacity hat which is basically two telescoping whip antennas mounted above the coil and parallel with the roof of the automobile. The helix radiates vertically-polarized rf energy in the radial, rather than axial, mode. . . similar to that from a conventional vertical antenna.

The CR1720A comes from the factory with a large magnetic mount that will defy almost any attempt to remove it accidentally from the roof of your car once it has been placed in position. The shunt feed has been factory-preset to provide the proper 50-Ohm feedpoint impedance, and a UHF chassis-type rf connector (SO-238) is located on the center support pillar just above the mounting base. Although it is normally used with the magnetic mount supplied by Com-Rad, the Mobile Ear can be used with any mount that is connected directly to ground, such as groundplane radials or the like. The reason for this is that the coaxial cable is connected to the antenna rather than to the mounting base; for proper operation, the base of the antenna should be grounded. For example, you might wish to replace the magmount with a permanent base for the home station, and this can be done by using the 3/8-24 bolt at the bottom of the antenna—the one that the magmount screws into.

The CR1720A comes completely assembled, except for attachment of the telescoping whips to the top of the support pillar. This is easily and quickly done by sliding the setscrew ends of each whip over the 5/16-inch stubs at the top of the support pillar and tightening the setscrews.

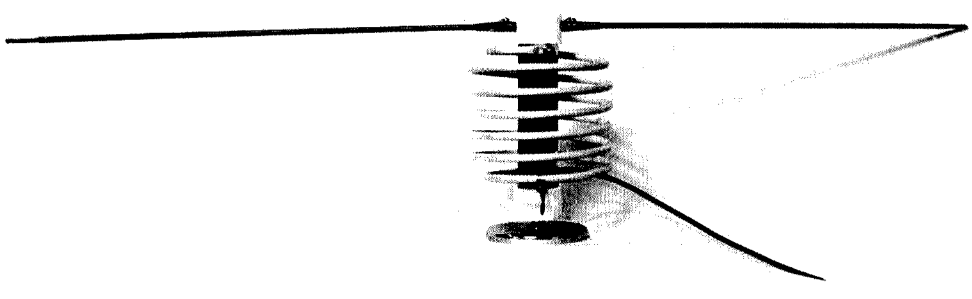
After you have mounted the antenna in the desired location on your car roof, connect an swr bridge in the line between the antenna and your transceiver or transmitter by means of a short length of coaxial cable, placing it as close as practical to the antenna itself (within two or three feet). Set the telescoping whips to approximately 50 inches each, and set your transmitter to the desired operating frequency. Apply a small amount of power and look at the swr. Small incremental adjustments of whip length by sliding the ends in or out (*out*—or longer—to lower the frequency and *in*—or shorter—to raise the frequency) will quickly provide a 1:1 vswr. Observe the lowest possible swr that you can get with your particular vehicle. If it isn't less than about 1.5:1, you can move the clamp ring of the shunt feed in tiny increments to achieve a perfect match. In the case of the test antenna, this wasn't necessary, as a perfect 1:1 match was obtained immediately.

I checked the bandwidth after achieving a perfect match and found that the frequency could be moved 65 kHz in either direction from the resonant frequency without exceeding 2:1 vswr. This means that with most rigs you can operate over your favorite phone or CW segment of the 20-meter band without any retuning at all. Of course, if you are a perfectionist, you can achieve exact matching at any frequency within the band. . . no sweat.

In the case of the test antenna, the inner sections of the whips were fully extended and the outer sections only partly extended. This gives the largest possible diameter at all times. I resonated the antenna at 14.025 MHz and found each whip length to be exactly 53¼ inches, measured from the surface of the support pillar. On the phone portion of twenty meters, I found that 14.3 MHz required a whip length of only 48½ inches. This is likely to vary slightly from car to car because of the different sizes of roof area, etc. A station wagon, for example, will have more groundplane area than a tiny subcompact, but both will work!

No doubt you are anxious to hear about results, and I won't disappoint you. The twenty-meter Mobile Ear really works. After tuning the antenna to resonance and firing up the *73* FT-707 transceiver (with my 1980 Olds Omega parked in my driveway), I found myself in the middle of the WAE contest on Sunday afternoon, August 15th. I answered many calls and received replies from each one. All were 599. Now, I'll admit that this is often the case in a contest, to make things easier for the report giver, but I got an answer to the first call every time! Not only that, but when I called CQ I got answers, too. In the space of only a few minutes I had worked UT5, UQ2, DL7, OZ1, OH5, UK5, G4, N9, KØ, and W4 lands! (Naturally, the US stations don't count, but I wanted to try the antenna.) To date, I've not done much with phone, as I am predominantly a CW operator. However, a few contacts up around 14.300 have been made with good results—G3, for example. . . and others.

I noticed that the noise pickup of the antenna is surprisingly low compared with other verticals I've tried. One possible explanation could be that the com-



Com-Rad's Mobile Ear antenna.

ponents are horizontally-configured and thus less subject to man-made or natural QRN.

I should mention that the CR1720A is beautifully made—the helix is heavy-duty aluminum tubing and the whips are stainless steel. The supporting pillar appears to be heavy-wall PVC and the magmount is chrome-plated steel. Everything considered, the CR1720A is a very fine portable/mobile/fixed antenna, one that the *73* staff really liked. You ought to know that the antenna doesn't need to be removed to put my car in the garage, so yours shouldn't need to be removed either, unless you want to. In public parking facilities, just slide in the whips, remove the coax, take the Mobile Ear off the roof and stow it in the trunk. It takes about 20 seconds . . . and, best of all, it can be remounted and ready to go in about the same time. In my case, I ran the whips fore and aft parallel to the car's centerline so that they wouldn't be sticking out into the side. If you live in an apartment or condo where outside antennas are forbidden, you might find one of the Mobile Ears to your liking.

By the way, the "17" part of 1720 means that this antenna will also work on the 18-MHz (17-meter) band whenever that becomes available to amateurs in the United States. The CR1720A is one of three Mobile Ears which cover 12/15 meters, 17/20 meters, and 30/40 meters: versatile, indeed. The CR1720A lists for $55 plus $4 shipping, direct from the manufacturer.

For further information, contact *Com-Rad Industries, 1635 West River Parkway, Grand Island NY 14072.* Reader Service number 487.

a lot, I suspect. It read: C/Q/THE/FASTEIET/GROWING/AMATEUR/RADIO/MAGAZINE/ That's operculiform sending . . . and does not surprise us.

BUNCH GETS BASHED!

The recent Bash debacle in Baltimore should put an end to the fantasy that Bash is doing anyone any good except Bash. I also hope it will shut up a lot of the hams who are moaning about the code and ignoring the fact that Bash has totally done away with any need for technical competence . . . or at least had until the Baltimore epic.

As usual, Bash collected his most generous fees and set about helping a large group of hopefuls to memorize the answers to the FCC exams. He drilled them thoroughly, as always. But this time the FCC had made some very minor changes in the wording of the exam, with the result that 89% of his group flunked. The word is that the changes were small, such as in some of the values in the math problems.

One of the new questions for the General class had to do with the yagi antenna, asking which way it radiated energy. Only *one* of the Bash trainees got this one right! We're dealing with massive ignorance of amateur radio theory, not superficial ignorance, with these memorization sessions and the Bash books.

You know, I've been writing about this problem for quite a long time now and I've had almost zero response from readers. I have yet to hear of one single case where an amateur or a club has protested to a ham dealer carrying the Bash books. Not one case of an irate ham tearing up the books. No protests to *CQ* for carrying the ads for these pernicious books. No, it is obvious that no one really gives a damn whether a newcomer to amateur radio has even the slightest technical knowledge or even the ability to pass a fair test. So why all the fuss about Morse code? Am I talking to a bunch of hypocrites?

The Bash books and the Bash high-priced blitz weekend course are designed for one thing: to help people cheat at the FCC exams and bypass the entry requirements. As long as you don't care if people cheat to get a ham ticket, why should you care whether they are sold by Sears along with a two-meter HT? I don't see any difference, do you? If you really, sincerely, believe that people who cheat to get their ham licenses are suddenly going to be wonderful and productive hams once they get the magic paper from the FCC, then you also believe in the tooth fairy and that Congress will balance the budget. In other words, you're crazy.

Frankly, I'd rather see Sears making all that money instead of Bash; at least we would have more than a tiny dribble of new hams. Bash, despite his heroic efforts, has only been able to bring in a few thousand new hams for us. True, he's probably responsible for much of the few we've had. But if we are going to go along with the Bash system, which you have wholeheartedly accepted, let's go all the way and get some mass merchandisers into the act.

You've seen this thing happening and you haven't done a damned thing about it. Why should I have any respect for you? The hypocrisy over the code just makes this all the more irrational. And don't try to tell me that this is all news to you. Baloney.

NO SECOND LANGUAGES

There has been a liberally-fueled effort to cope with the inrush of Hispanics by allowing them to continue to use Spanish in school rather than force them to learn English. Fortunately, there is now a gathering movement against this policy. We showed that the "melting pot" system worked in America and then we tried to ignore it.

The more we keep newcomers to the United States able to make do without learning English, the more we are taking away from them the benefits which they presumably came here for. I'd like to see our schools teaching foreign languages, but not catering to students who do not have a solid use of English. I'd like to see the publication of foreign-language newspapers and foreign-language radio and television programs discouraged.

The lesson in Canada of how different languages split a country should be heeded. When a group in a country holds on tight to its language and culture, it is a disruptive force. Americans living in other countries tend to stick together and avoid learning the language as much as possible. This hurts both them and the country in which they are living.

The Indians (Asian) have long had a problem with this. In every country where there are a significant number of Indians, they are clannish and generate resentment with the other people. We don't have many Indians in the US, so we are not aware of them, but we do see the Chinese, who have the same problem. For many years we sort of accepted that the Chinese for some reason don't know English and run either laundries or restaurants.

Both the Indians and the Chinese are very hard-working people and, I suspect, if either group had made an effort to integrate into their new countries, they would have virtually taken over. Of course, Americans used to be hard-working people . . . and a few still are . . . but for the most part I see few remnants of this heritage. Perhaps we are most fortunate that the Chinese in America are so clannish and thus are kept from enjoying and benefitting from our educational opportunities.

We still live in a world where hard work pays off. This is one of the reasons we have so few wealthy people. Given equal opportunity, I suspect that the US would be as proportionately populated with wealthy Chinese as it is wealthy Jews. In Taiwan, Hong Kong, and Singapore, we see how well the Chinese can do when they are not held down by Communism. Perhaps we are fortunate, in a way, that the political systems in China have been so destructive. I'm sure that the Chinese could, if working in a free country, run circles around us.

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego, 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lamar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Diego CA

We buy and sell Surplus Army Navy Electronics, also Terminated Material. What do you want to sell? Write for catalogue. **Electronictown, Inc., 440-7th Avenue, PO Box 2048, San Diego CA 92112, 232-9379.**

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full Line of Accessories. No Sales Tax in Delaware. One mile off I-95. **Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Smyrna GA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. **Britt's Two-Way Radio, 2506 N. Atlanta Rd., Smyrna GA 30080, 432-8006.**

Preston ID

Ross WB7BYZ has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 478003, 238-1456.**

Baltimore MD

Always buying lab grade test equipment HP, Tek, Gr, L&N, Etc. Also buy microwave coaxial & waveguide HP, fxr, waveline, etc. Prefer "K", "P", "R" but will consider larger wg too. **Cadisco 514 Ensor St., Balto, MD 21202, 685-1893.**

Littleton MA

The Reliable Ham Store Serving N.E. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. **TEL-COM Electronic Communications 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, DenTron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.**

Hudson NH

New England's Distributor and Authorized Service Center for all Major Amateur Lines. **Tufts Radio Electronics, Inc., 61 Lowell Road, Hudson NH 03051, 883-5005.**

Somerset NJ

New Jersey's only factory-authorized ICOM and Yaesu distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.**

Buffalo NY
WESTERN NEW YORK

Niagara Frontier's only full stocking Amateur dealer. Also Shortwave, CB, Scanners, Marine, Commercial. Operating displays featuring Kenwood and others. Towers, Antennas, Sales and Service. **DX Communications, 3214 Transit Road, West Seneca NY, 668-8873.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Syracuse-Rome-Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy-Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 736-0184.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

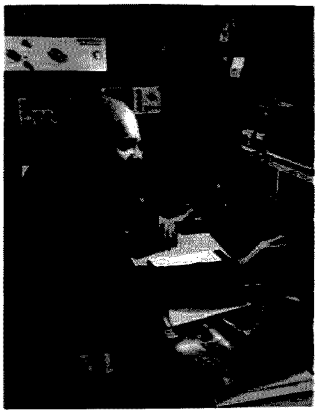
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



SHOULD DXCC BE PROHIBITED?

The blatant arrogance of the PY0SB DXpedition shook the amateur bands, bringing on wild attacks of jamming in retaliation. Frankly, after trying to use the twenty-meter band for an hour, I didn't blame the jammers much. Not since Don Miller have I heard such a total disregard for the hobby.

This was, in my estimation, amateur radio at its worst. Those refugees from CB set up on one of the most rare spots in the world and then, transmitting outside of the American phone band, asked US hams to call them anywhere from 14,200 to 14,300. This went on, totally killing the band for any other use as thousands of stations called steadily, hour after hour. There was no possible way to make a normal contact anywhere in that entire band while this was going on.

This is totally unnecessary, as anyone with even a small amount of DXing experience knows. It is arrogant. It is a shameless flaunting of the power of one group to bring the whole band to a halt. It isn't even a fast way of making contacts. There is not even a remote excuse for such a display.

I've operated from some fairly remote spots and have faced as big pileups as anyone. I got started in seriously working DX in late 1945, the day our first DX band opened after the war. When I moved to New Hampshire, I started all over again, working 100 countries in the first week on twenty phone, 200 in the first month, and 300 in the first year. So I know the receiving end of the stick.

In 1958, I went on my first serious DXpedition...KC4AF, Navassa Island. Since then, I've operated from a bunch of places...come to mind 5Z4, ZS6, 3D6, 7P8, OD5, YK1, YA1, VU, 9N1, HL6, VR2, 5W1, KS6, FO8, HH, JY, OH0, KH2, KW6, and a bunch of non-rare countries. I've tried every way known to ham to get the most contacts per hour on the air from these rare places, so I have a good idea of what works and what does not work. Hmmm, I forgot to mention VP5, J6, and a revisit to Navassa in 1972.

The results of all this? Well, unless your signal is particularly weak, the fastest operation is when you operate on a fixed channel, thus containing the band mayhem to one single pileup. I've found that out by making regular announcements to this effect: "I will be listening for about ten seconds on this channel for the last letter of your call. Please do not all jump in immediately, but wait so your calls will be spaced a bit. I will make a note of the last letter of your call and call you with it after writing down as many as I can hear. Do not...I repeat...do *not* call more than a couple of times. If I hear anyone pushing and shoving on channel I will work you, but there will be no QSL. Neither of us wants that."

The result is a relatively orderly sorting out of the problem, which is to get the call letters of those on channel as quickly as possible. The rest of the contact is a matter of a couple of seconds. The long, hard part is getting the calls through.

By asking for the last letter, I am able to quickly get things down to two or three, at most, responding when I break. It makes everyone shut up and listen. I can then confirm the call, exchange signals, and be on to the next. With this system, I can double or triple the throughput of any system which calls for tuning a band of frequencies, looking for calls in the open.

The calling stations, perceiving that I am able to cope with the chaos and that they will have a fair chance of getting through, respond very positively and line up, doing as I ask. Megawatts of power are saved. The entire band, except for about 6 kHz which I am using, is open for everyone...and at least twice as many operators are made happy with a new one. And think of the agonizing frustration saved for the thousands of ops, calling hour after hour, hoping to get through.

Another solution to the whole problem would be, of course, to get the League to cancel their Honor Roll and DXCC certificates so we wouldn't have this enormous pressure to make a radio contact with some stupid island somewhere. That would spoil a lot of fun for thousands of us DXers, but it would at least stop such carnage as the Peter and Paul jokers dumped on us.

This whole DX thing, while it may be fun for amateurs in most of the ordinary countries, is a royal pain in the...er...ear for the ham who lives in a rare spot.

HAM BILL SIGNED

It began as S.929, turned into H.R.5008, and came out of the Washington mill as H.R.3239, but the effect is the same: sweeping changes in amateur radio.

The bill, which has been signed by President Reagan, will give hams more control over licensing and policing and may also expand the 5-year ticket into a license renewable every 10 years.

With this moneysaving measure, FCC-approved hams and ham organizations will be both writing and administering exams. However, the exams may be written only by a ham with at least the class license that the exam is for, and tests can be given only by hams with a higher-class license. Extras, of course, will be allowed to test Extras.

Amateur radio's traditional self-policing policies have also been given a shot in the arm by the bill. The FCC can now use hams to track down illegal transmissions and accept reports on illegal activities which have been filed by hams. This bill gives the FCC permission to "recruit and train" hams for this purpose, and these amateurs will also be allowed to send warning notices to offenders. However, the amendment does not give hams authority to officially charge violators.

The self-regulatory aspect of the bill is the brainchild of Sen. Barry Goldwater K7UGA, who drafted the initial version as S.929. But to get it enacted, the concepts of S.929 were incorporated into a larger house bill, H.R.5008, which addresses a wide variety of changes in the Communications Act of 1934.

Hams plagued by RFI will find some respite under this bill, which will "establish minimum performance standards for home electronic equipment and systems to reduce their susceptibility to interference from radio frequency energy." However, the bill does not affect equipment already manufactured.

Other changes in the Communications Act eliminate licenses for CBers and radio control operators. Though CB operators will still be expected to comply with regulations, the change allows the Commission to officially wash its hands of the 27-MHz band.—WB8JLG.

You wouldn't believe how soon the thrill of working stations for ten-second contacts palls. You might not find it as difficult to believe what a nuisance being expected to fill out and mail thousands of QSL cards is. Imagine, if you will, the excitement with which a ham in Tonga receives his 780th QSL from a WB2 station. It just goes into the nearest leftover washing machine carton.

Even with a QSL manager to take on the brunt of the card chore, the responsibility for keeping the log, getting a copy to the manager, and forever making instant contacts, with growing resentment whenever you stop to try to make friends with anyone forcing you to shut down... it's driven most hams in rare spots off the air.

QSL OF THE MONTH: XE1JRV

This month's QSL Contest winner is Jesus Retana XE1JRV. This modern rendition of an ancient temple is highlighted by the bright yellow sun, adding warmth and contrast to an otherwise stark scene.

To enter *73*'s QSL of the Month Contest, put your QSL card in an envelope with your choice of a book from *73*'s Radio Bookshop, and send it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries without an envelope or book choice will not be considered.

With so many things of value which people can accomplish in this world, I am saddened when I see some ham who has gotten swept up in the DX Honor Roll excitement. What a frivolous waste of life it is to devote it to trying to make this silly list... and stay there... often at almost any expense.

The Hangman's 2-Meter Collinear

Make your tower do double duty. Drop this array from the top and get 6-dB gain.

Here is a 2-meter FM base-station antenna that's inexpensive, easy to build, and has about 6 dB omnidirectional gain. It can be mounted on the side of a tower or put on a mast of its own. No special tuning equipment is required. All you need is an swr meter.

Design

The antenna described here is a 6-element vertical collinear array. It consists of six half-wave radiators placed end-to-end and fed in phase. The resulting directional pattern is theoretically a circle in the horizontal plane, with a gain of about 6 dB over a dipole. Results of testing at W1GV/4 indicate substantial improvement, both for transmitting and receiving, over a 5/8-wave antenna with ground plane at 25 feet.

Fig. 1 shows the configuration of the collinear antenna. Each element is 38 inches long. The end-to-end spacing between elements is negligible, about 1 inch. Allowing for a foot or two at the top and bottom, the entire antenna requires a vertical space of about 22 feet. Of course, the higher the system is placed, the better the performance will be.

Proper phasing is obtained by quarter-wave stubs between the elements. For all practical purposes, these stubs do not radiate, provided they are cut to the correct length. At 146.5 MHz, 18 inches with 2-inch spacing gives a reasonant, ultra-low-loss matching section. Fig. 2 illustrates the construction details for each stub.

The antenna can, as previously mentioned, be mounted on the side of a tower or alongside a TV mast; it can even be hung from a tree branch! If the antenna is mounted on the side of a tower, the directional pattern will be modified slightly. The gain will be reduced in the direction of the tower and increased in the direction away from the tower. Therefore, you should position the antenna to provide the most gain in whatever direction you desire the best coverage (Fig. 3).

If the antenna is suspended next to a TV mast or hung from a tree limb, the pattern will be omnidirectional.

Construction

To put this antenna on a tower, you will need the following hardware, in addition to the usual tools and soldering apparatus:

- 6 42-inch lengths No. 12 solid uninsulated copper wire

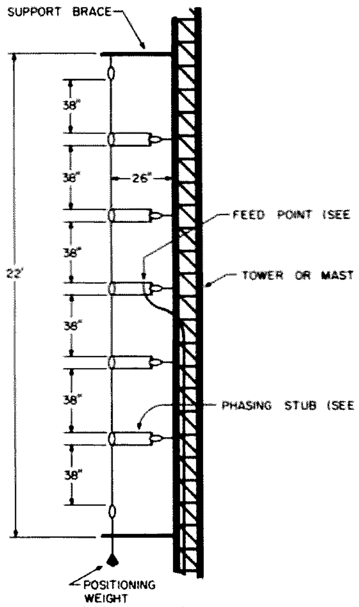

Fig. 1. Configuration of the 6-element, 2-meter wire collinear antenna. The overall height is 22 feet. The array is fed at the physical center.

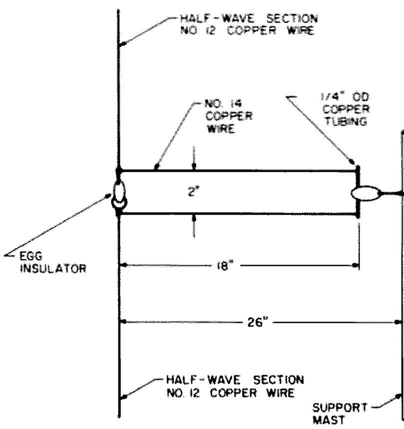

Fig. 2. Construction details for the tuning stubs. A spacing of 2 inches provides minimum loss while allowing essentially no radiation. When the stub is pulled tight, the wires will stay in place because of their stiffness.

● 10 20-inch lengths No. 14 solid uninsulated copper wire
● 1 20-foot (approx.) roll No. 12 solid wire
● 5 2-inch lengths 1/4-inch o.d. copper tubing
● 5 porcelain insulators (non-egg type)
● 7 small egg insulators
● 2 3-foot, 2-inch o.d. wooden dowel rods
● 2 screw-in-type TV standoff insulators
● 1 15- to 20-pound weight
● 1 roll of electrical tape
● 1 strong set of legs

First, screw the TV standoffs into one end of each dowel. Then, attach the rods sideways to the tower braces, 22 feet apart. (If the tower braces do not exactly line up to 22 feet, use the next brace that will allow a spacing greater than 22 feet.) Of course, the higher the overall position, the better! The dowels should extend 26 inches out from the tower. Use No. 12 wire to secure the dowels to the tower braces.

To assemble the antenna, attach the seven egg insulators at the ends of the six antenna elements, making a long chain. Wrap and solder each wire end to the egg insulators. To minimize interelement capacitance, it's best to loop the wires through the egg insulators as shown in Fig. 2, in such a way that if the insulator should break, the wires will come apart. The elements should each measure exactly 38 inches from loop tip to loop tip. Attach an 18-inch length of No. 12 wire to one end of the array and a 48-inch length to the other end.

To construct the phasing stubs, solder two 20-inch lengths of No. 14 wire to each element end (see Fig. 1). Wrap 1 inch of wire around each element end. Space the wires 2 inches apart. Put a 2-inch piece of copper tubing through one end of a standard porcelain or glass insulator and twist a short piece of stiff wire

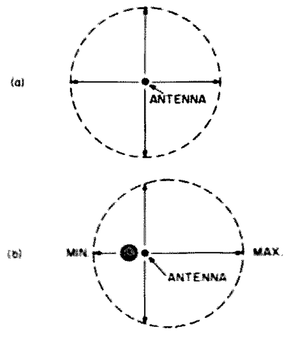

Fig. 3. Radiation patterns for a vertical array in free space (a) and near an obstruction such as a tower (b). The viewing position is directly overhead. The obstruction tends to reduce the gain in some directions while increasing it in others.

around the tubing if necessary to keep it from slipping up and down in the hole. Wrap 1 inch of the free ends of the stub wires around the ends of the tubing and solder them in place. When you are done, you should be able to pull the stub tight and have both wires evenly spaced, straight, and 18 inches long (Fig. 2). You will have to construct five of these stubs, in locations shown by Fig. 1.

Now you're ready to hang this contraption. Grab the top end—the one with the 18-inch piece of wire attached—climb the tower (don't forget your safety belt!), and affix the wire to the TV standoff insulator at the end of the upper dowel. Then, climb back down to the lower dowel and run the 48-inch end wire through the standoff insulator there. Rotate the plastic inside the standoff so the wire can't pop out, and crimp the insulator ring to keep it in place. Cut the lower wire so that roughly 8 inches remains below the standoff. Then attach the weight to the end of the wire (Fig. 4). This weight keeps the array taut as the wires expand and contract with changes in temperature. An alternative arrangement to the weight is

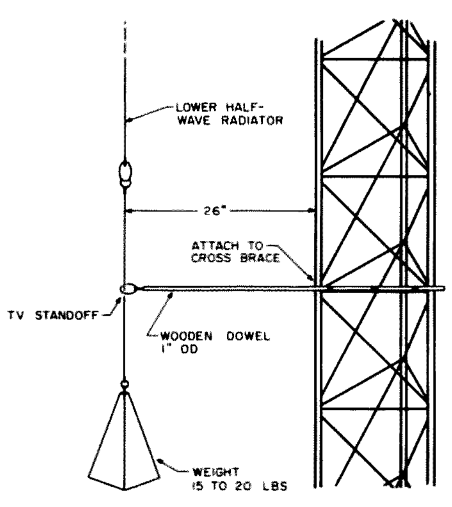

Fig. 4. Arrangement for keeping the array taut. The distance between the weight and the TV standoff should be great enough to allow for contraction with cold weather, but small enough to prevent excessive swinging of the weight.

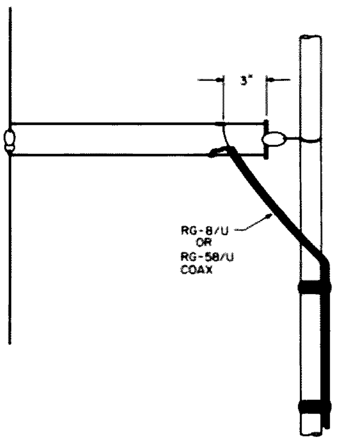

Fig. 5. Feedpoint diagram. The array should be fed at the center stub. A good starting point is 3 inches from the shorted end; however, some adjustment will probably be necessary to get a perfect match. Here, the center conductor of the transmission line is connected to the top part of the antenna and the shield to the bottom part. However, they could just as well be reversed.

to use an elastic band in place of the lower section of wire; however, the array may have a tendency to "oscillate" in the wind if this scheme is used.

To position the stubs, you'll need five pieces of wire about two feet long. Run one end through the insulator at the end of the stub, twist the wire onto the insulator, and pull the stub reasonably tight. Twist the other end of the wire around the tower support nearest the array (Fig. 2).

The Feedpoint

You can rest a bit now. As you're sipping a cool drink, admire the new appendage to your antenna farm. But don't get carried away; you still don't have it hooked up. And the final tuning procedure may require three or four more excursions up the tower.

Fig. 5 shows the matching section for the 6-element wire collinear. The transmission line is connected to the center stub. A good starting point

is 3 inches from the shorted end, as shown. However, you'd better not solder the wires there right away. The size of your tower will have some effect on the exact final position. Larger towers will lower the impedance for any given tap point, as compared to smaller towers.

The feedpoint should be moved slightly toward or away from the shortened end of the stub until the swr is minimum at 146.5 MHz. It should be possible to get a nearly perfect match (at W1GV/4, a 1.3 swr was obtained). Always keep the coax shield and center-conductor taps at the same distance from the end of the stub; don't try to get fancy by putting them in different places.

The final tap position will be about 15 percent of the way from the shorted end of the stub to the antenna end. When the ideal position has been found, solder the wires in place and wrap the connections with electrical tape. Or, better, use silicone rubber cement. Tape the feedline cable to the inside of the tower to minimize possible induced currents on the coax from antenna coupling.

Closing Remarks

This antenna is a pleasure to use and requires essentially no maintenance. Since it is made from materials usually available at flea markets, the cost can be very low. I had much of the necessary hardware already in my junk box.

A gain of 6 dB over a dipole represents a quadrupling of the effective radiated power. But you get this gain on receive, too! With my Azden PCS-3000 at 25 Watts, I'm running 100 Watts effective radiated power, neglecting line losses. My installation, being attached to a TV mast with the bottom almost at ground level, is essentially omnidirectional. It is generally possible, in this pancake-flat South Florida area, to communicate with mobile stations via simplex out to 50 or 60 miles. Before, with the 5/8-wave antenna at 25 feet, the reliable range was only 30 to 40 miles. Of course, repeater operation is a breeze. I'm full-Q into all of the local repeaters.

There isn't any reason why more elements cannot be added to this array, except for height limitations and certain engineering requirements. An 8-element array would require about 28 feet of vertical space and would produce about 7.5 dB gain over a dipole; a 10-element array would give around 8.5 dB gain.

As the number of elements is further increased, tuning of the stubs and elements becomes more and more critical, and special equipment will be required to ensure correct phasing for optimum performance. (Even with a 1-inch error on each element, the total discrepancy would be 5 inches at the top and bottom of a 10-element array; this is 23 degrees at 146.5 MHz! Such an imprecision would surely degrade the performance of the antenna.) Furthermore, as the number of elements increases, the bandwidth of the array gets narrower because the error adds up for each element off resonance. There is a point of diminishing returns.

A 6-element array can provide good communication without the headaches of painstaking adjustment and narrow bandwidth, and so it represents a good compromise. This antenna is ideal for the 2-meter FM operator who wants omnidirectional operation, but is presently using only a ground plane.■

Deep-Six Squelch Tails

Kerchunks take a dive with the addition of this audio delay.

Squelch tails are ugly. Few things are more annoying to repeater users than a long squelch tail every time someone drops his carrier. At WR3AFM, a Baltimore Amateur Radio Club (BARC) multiple-receive-site repeater,[1] this problem is compounded by a second squelch tail, that of the link receiver. The resulting overall squelch tail is approximately 110 milliseconds in duration. However, thanks to the circuit described below, it is no longer audible.

A squelch tail is the noise heard at a receiver's audio output after the transmitting station has dropped its carrier but before the receiver's squelch circuit can mute the audio output. This is what you hear whenever the repeater carrier drops off the air, for example. The duration of the squelch tail is a function of your particular receiver.

Another source of squelch tails is a repeater receiver. Consider first a conventional single-site machine. Whenever the transmitting station drops its carrier, the repeater receiver's output follows with a burst of squelch noise. Since the repeater transmitter is still on the air at this point, this squelch tail is heard by all stations monitoring the machine.

Next, consider a split-site repeater (or a multiple-site repeater like WR3AFM) as shown in Fig. 1. In this type of setup, the repeater receiver (or each satellite receiver in a multiple-site scheme) is coupled to the repeater transmitter via a link, often on 450 MHz. The repeater receiver operates as before, appending a squelch tail to each transmission. The receiver output is sent by the link transmitter to the repeater transmit site, where it is received by the link receiver. When the link transmitter carrier drops, shortly after the repeater receiver squelch tail ends, the link receiver will append a squelch tail of its own to the audio output. Since the link receiver feeds the repeater transmitter (or voter, in the multiple-site case, which, in turn, feeds the transmitter), this (link) squelch tail also is heard by all monitoring stations.

In order to eliminate the squelch tail nuisance, a delay line was inserted into the audio-signal path. To see how this will allow the squelch tail to be silenced,

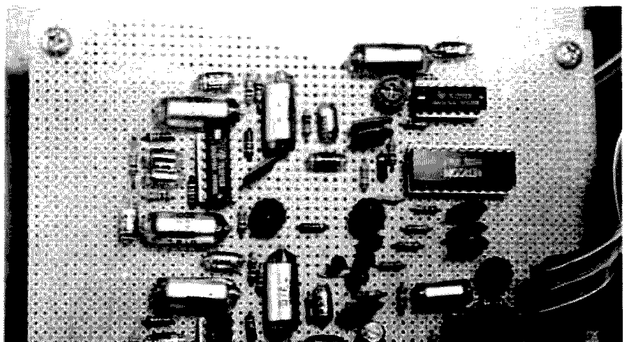

Photo A. The completed board installed at WR3AFM. The delay line is in the upper right. The I/O connector is in the far right. (Photo by N3IC)

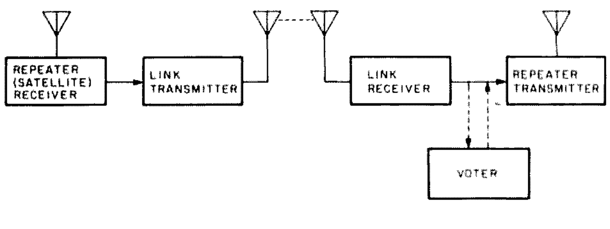

Fig. 1. Split-site (or multiple-site) diagram.

Reader Service for facing page ✓ 191 →

refer to Fig. 2. Note that although the figure specifically illustrates the multiple-site (or split-site) system, by ignoring the link (second) squelch tail it is valid also for a single-site system.

Fig. 2(a) shows the audio output of a satellite receiver and its associated squelch tail. This signal is sent via a link transmitter to a link receiver, and from there to the voter, with the added link receiver squelch tail. The audio output of the voter, shown in Fig. 2(b), contains the satellite receiver squelch tail and the link receiver squelch tail. The carrier-operated switch (COS) depicted in Fig. 2(c), with logic high equivalent to on and logic low equivalent to off, changes state after both squelch tails are completed. Since the COS is usually employed to gate (switch on or off) the repeater transmitter audio (or the transmitter itself), both squelch tails are transmitted by the repeater.

Fig. 2(d) shows the voter audio output delayed in time. It can be seen that the squelch tails in Fig. 2(d) occur after the COS goes low. Using the COS signal to gate the audio in Fig. 2(d) gives Fig. 2(e). This audio contains no squelch tail at all.

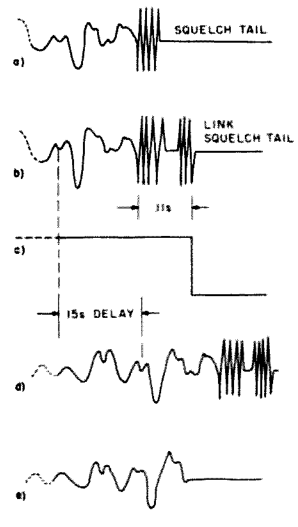

Fig. 2. Using delayed audio to eliminate squelch tails. (a) Repeater (satellite) receiver audio output. (b) Link receiver audio output. (c) COS. (d) Delayed link receiver (voter) audio output (e) Gated repeater transmitter audio.

The length of the satellite-receiver squelch tail is somewhat dependent on the received signal. Since the link transmitters and receivers are fixed, the link squelch tail is always the same length. To take this variability into consideration, the length of the delay was chosen to be longer than the worst squelch tail usually encountered. This ensures absolutely no transmitted squelch tail, but also chops off a small amount of audio in some cases. At worst, however, if the carrier is dropped immediately following a word, one syllable might be lost. This turns out to be insignificant in practice. Of the almost 500 members of BARC, only one seems ever to have problems with lost syllables, and then only on one-word transmissions! Overall performance has been great, and the total parts cost of approximately $70 puts the project within reach of most everyone.

General Theory

A block diagram of the overall system is shown in Fig. 3. Starting with the delay itself, the various blocks will be examined.

The heart of the circuit is a Reticon R5101 Charge-Coupled Device (CCD) which performs the delay. The CCD acts as an analog shift register. It stores time samples of the analog input signal as packets of charge. The amount of charge in each packet is proportional to the amplitude of the analog input at the time of sampling. The packets of charge are shifted through 2000 stages before they reach the output of the CCD. Thus, the chip has 2000 samples of the input stored at any given time, each separated in time by T seconds, where T is the time between samples. The CCD uses two clock cycles per shift, and hence the overall delay time (Td) is given by $Td = 2000 \times (2/Fc)$, where Fc is the clock frequency supplied by the oscillator block and is equal to 2/T.

Instead of using a CCD, other schemes could be used to achieve the desired delay. These include tape loops and digital sampling, which are discussed briefly below.

The tape-loop scheme involves continuously recording and simultaneously playing back the received audio on a tape recorder. Since there is a physical gap between the record head and the playback head, a time-delay is introduced ($Td = G/V$, where G = gap length in inches and V = tape speed in inches per second). A Td of up to one second is typical at slow tape speeds with this approach. This scheme is the simplest to implement, but was not used because of the problems of reliability of such factors as the tape transport mechanism, tape breakage, and dirt on the tape heads.

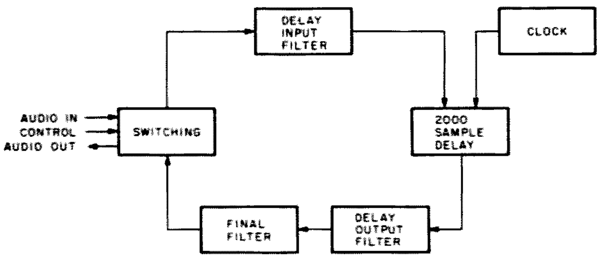

Fig. 3. System block diagram.

The digital-sampling scheme is similar to the CCD technique except that the audio signal is first digitized by an analog-to-digital converter, then stored in a digital shift register, and finally converted back to analog form by a digital-to-analog converter. This approach has the advantage of being able to achieve any desired delay by adding more shift registers. To get a reasonable signal-to-noise ratio and still preserve the dynamic range of speech, we would need either many bits (12 or more) in the digital words or we would have

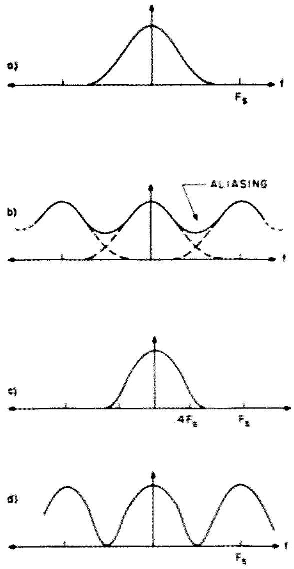

Fig. 4. Aliasing. (a) Spectrum of signal to be sampled at F_S (b) Spectrum after sampling without first low-pass filtering. (c) Spectrum of input signal after low-pass filtering with cutoff at .4 F_S. (d) Spectrum after sampling the low-pass-filtered signal.

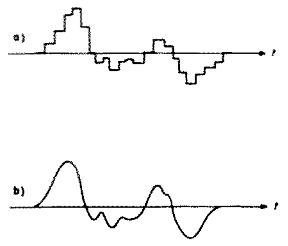

Fig. 5. CCD output filtering. (a) Before filtering. (b) After filtering.

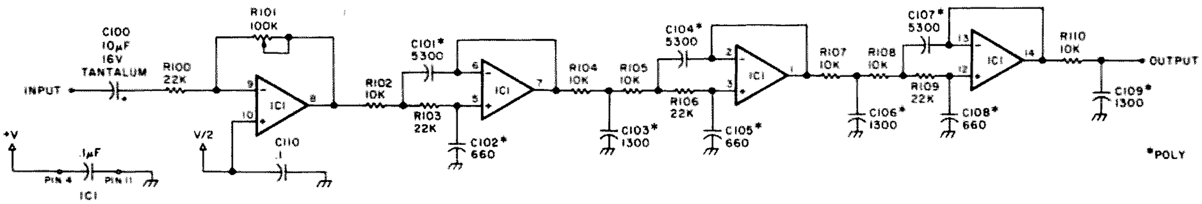

Fig. 7. Delay input and delay output filtering. Note: IC1 and IC2 are TL074Cs. IC1—100 series; IC2—200 series.

Frequency (Hz)	Gain (dB) (I/O 2 to I/O 6)
12	−3
20	−1.32
50	−.21
100	0
1k	.53
2k	1.59

2.37k	1.59
3k	0
3.43k	−3
4k	−10
5k	−30
6k	−51

Fig. 6. Measured overall response. Conditions: 1) Delay = 150 ms (F_{clock} = 26.67 kHz); 2) two-pole adjustable low-pass filter set for 0 dB at 3 kHz.

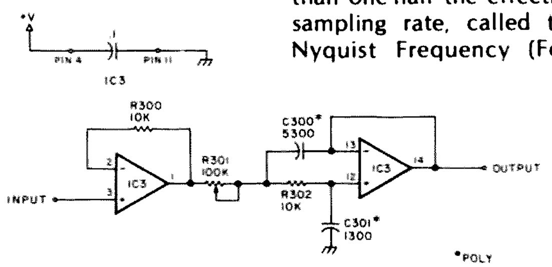

Fig. 8. Final filter. IC3 is a TL074C.

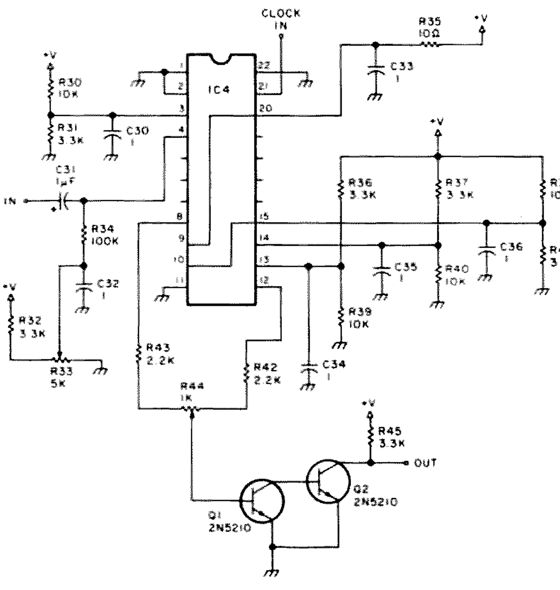

Fig. 9. 2000-sample delay. IC4 is a Reticon R5101.

to use a compression-expansion (companding) technique. Either way, due to the high cost of analog-to-digital converters and digital memory (the shift registers) and because of its higher total package count, these approaches were undesirable.

As in any time-domain sampling system, the input must be a band-limited process. In a low-pass application, such as with speech, any input components whose frequency is greater than one-half the effective sampling rate, called the Nyquist Frequency (Fc/4 here), must be removed prior to sampling to prevent a form of distortion called "aliasing." If not removed by filtering, these components will appear at the output as lower frequency (alias) signals (see Fig. 4).[2] Once aliasing occurs, it cannot be removed by filtering, since the aliased components are indistinguishable from the original components. The necessary filtering is performed here by a 3-section, 9-pole low-pass filter.

Since the CCD is a discrete time system (that is, its output changes only at specific times, resembling a staircase), the output also contains high-frequency terms which must be removed by filtering (see Fig. 5). This filtering is again performed by a 3-section, 9-pole low-pass filter.

Since the frequency response of the CCD is somewhat dependent on the clock frequency selected, a tunable low-pass filter is provided. By tweaking this filter, the overall response may be optimized for a particular clock rate. The response for the board at WR3AFM is given in Fig. 6. The tunable filter was set so that the response at 3 kHz was equal to that at 100 Hz (0 dB). Notice the excellent flatness over the speech bandwidth (−0 dB, +1.6 dB). The steep roll-off past 3 kHz also serves to attenuate wideband noise from other sources preceding the delay line.

Variable-gain input and output buffers are provided. The input buffer is set to limit the input to the CCD to less than 1 volt peak to prevent overloading the device, and the output buffer is set to achieve unity overall gain (0 dB) at 100 Hz. Thus, the whole board is transparent to the rest of the repeater.

The switching stage allows the delay to be bypassed (if desired) and permits the audio to be gated with the COS signal. This eliminates the need for any external audio switching.

Circuit Design

Filters

The circuit was designed in a fairly straightforward manner. Quad bi-FET op amps were chosen because their high input impedance makes designing with them simple. Specifically, the TL074 is a low-noise version of the popular TL084, which could be substituted, as could many other audio op amps.

Since the frequency response of the CCD starts to roll off at about 1.5 kHz when set for a 150-millisecond delay, some form of equalization was required to extend the usable bandwidth of the system. High-frequency pre-emphasis (that is, boosting the high-frequency components ahead of the CCD, as opposed to post-emphasis) has the advantage that the input signal is kept large with respect to the noise at all times. However, since the CCD overloads at about 1-volt peak input, any boost in the spectrum ahead of the CCD must be accompanied by an overall cut in the input level (relative to that permissible with no pre-em-

phasis). Post-emphasis completely avoids this problem, but it also boosts any noise added by the CCD circuitry. As a compromise, equal amounts of pre- and post-emphasis were employed.

The low-pass filters were designed to provide the needed boosting as well as to attenuate the high-frequency components. In order to achieve a 150-millisecond delay, Fc = 26.67 kHz from the equation, above. Thus, the Nyquist Frequency (Fc/4 here) is 6.67 kHz. The low-pass filters must attenuate at and above this frequency. The 9-pole filters shown in Fig. 7 have a peak (boost) of approximately 6 dB before rolling off at −54 dB/octave. The overall response is shown in Fig. 6.

The final output filter, a buffer and 2-pole low-pass filter combination, is shown in Fig. 8.

CCD/Clock

Fig. 9 shows the circuitry surrounding the CCD that was suggested by the manufacturer, which was found to work well. The clock signal is produced from a simple two-inverter oscillator and is shown in Fig. 10.

Switching

Since WR3AFM is controlled by an 8080 microprocessor, all control signals are supplied by TTL open-collector outputs. Thus CMOS 4066 analog switches were a natural choice to handle the audio gating. The switching circuits are shown in Fig. 11.

Construction Notes

The board was built using point-to-point techniques. The actual layout, shown in Fig. 12, was carefully planned to ensure neat wiring and no ground loops. Any popular construction technique should work. Whatever method is used, however, the ground leads should be heavy enough to keep op-amp noise reasonable.

All op-amp Vcc inputs were bypassed to ground with a .1-uF disc capacitor right at the chip, on the underside of the board. Polystyrene capacitors were used in the filters to achieve close tolerance and good temperature stability. Sockets were used for all chips, with the one for the CCD being a must.

The input and output audio, switching, and power-supply connections can conveniently be made using ribbon cable and a 14-pin DIP socket. A suggested pin configuration is shown in Fig. 13. Unused lines should be grounded at the board end only, to reduce noise and prevent ground loops. The ground lead from the DIP socket should be connected to the ground bus on the board at the spot that results in the smallest amount of noise on the audio-output line. In the layout shown in Fig. 12, the best spot was found to be near the inverter chip.

Finally, as shown in Fig. 14, a 10-uF filter capacitor was placed from Vcc to ground and from Vcc/2 to ground. Tantalum capacitors were used because of their small size and low leakage, but any type capacitor will do.

Parts

The CCD is available for $50 from Reticon Corporation, 910 Benicia Avenue, Sunnyvale CA 94086, and their distributors (write to them for info). For most other parts, a good supply house is Digi-Key Corporation, PO Box 677, Thief River Falls MN 56701.

Adjustment

To set the clock fre-

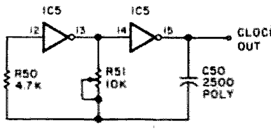

Fig. 10. Clock. IC5 is a CD4049AE.

quency, adjust R21 while observing pin 15, IC5, on a scope or frequency counter. The desired frequency may be found from the equation, above. For a 150-millisecond delay, Fc = 26.67 kHz.

R101 is adjusted to prevent overloading the CCD. Since the maximum pre-emphasis is 6 dB, the maximum signal at pin 8, IC1, must not exceed .5 volts peak for any input signal. However, to achieve the best signal-to-noise ratio, it is desirable to keep the signal as large as possible. Therefore, apply a sine wave at the maximum level to be encountered in operation (such as the level that gives 5-kHz deviation on the repeater) to the input (I/O pin 2) and adjust R101 until the level at pin 8, IC1, is .5 volts peak.

To adjust the bias and symmetry of the CCD, apply an audio-frequency sine wave to the input (I/O pin 2). Adjust the amplitude of the sine wave until distortion is just evident at pin 14, IC2. Next, set R33 and R44

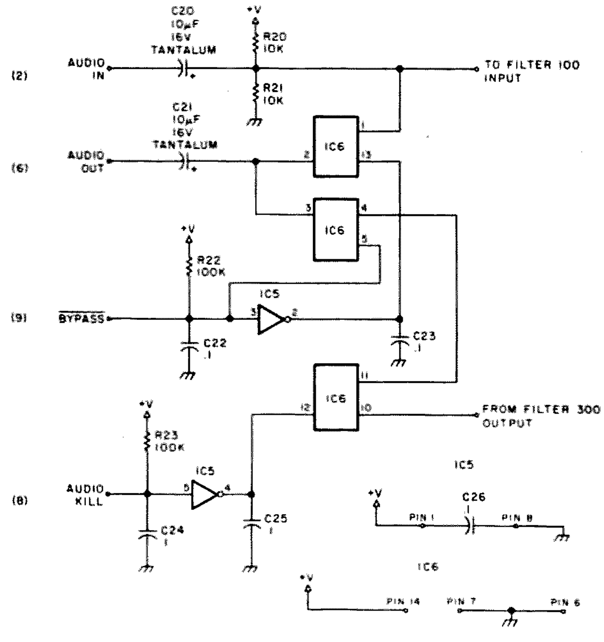

Fig. 11. Switching. IC6 is a CD4066.

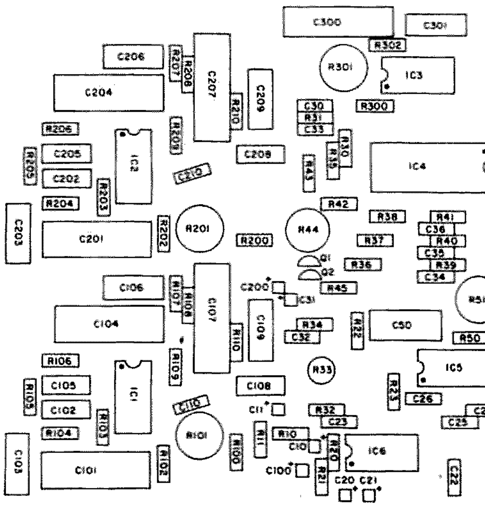

Fig. 12. Parts layout.

to minimize the distortion, and then increase the input until the distortion is again visible. Continue this process until no further reduction in distortion is observed.

Adjust R301 so that the overall gain is equal (I/O pin 2 to I/O pin 6) at 100 Hz and 3 kHz. This gives a desirable response for a voice channel.

Finally, adjust R201 so that the overall gain (I/O pin 2 to I/O pin 6) is unity (0 dB) at 100 Hz (or 3 kHz).

Pin 2—Audio input
Pin 6—Audio output
Pin 7—Ground
Pin 8—Audio kill
Pin 9—$\overline{\text{Bypass}}$
Pin 14— + 12 volts

Fig. 13. I/O connector wiring.

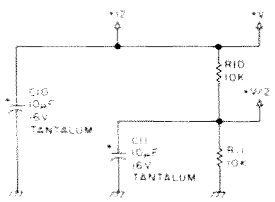

Fig. 14. Power supply filtering.

Echoes, Etc.

Since the unit introduces delay in the audio path, a rather interesting echo effect can be observed. Referring to Fig. 15, notice that due to the delay some audio output continues from the repeater after the transmitting station's carrier drops. The length of this audio is equal to the length of the combined squelch tails. Depending on the speed of the station's T-R switching, the operator will hear the end of his transmission coming back.

The only drawback of the device also is visible in Fig. 15. The final portion of audio is chopped by the circuit. The amount of audio lost is equal to the difference between the length of the delay and the length of the combined squelch tails. Since the usual squelch tail lasts for 110 milliseconds (at WR3AFM), if a short squelch tail was acceptable, the delay could be shortened to 110 milliseconds. In practice, almost everyone holds their PTT for a short amount of time after they stop speaking, so this is really a moot point.

The delay also causes a strange phenomenon if an operator is monitoring the repeater on a secondary receiver. It is virtually impossible to talk while listening to your own voice delayed by 150 milliseconds. This effect has encouraged the more fun-loving walkie owners to engage in the friendly game of sneaking up behind an unsuspecting repeater user while he is transmitting and then turning up the volume on the walkie. This fun alone justifies the work involved in building the delay line. ■

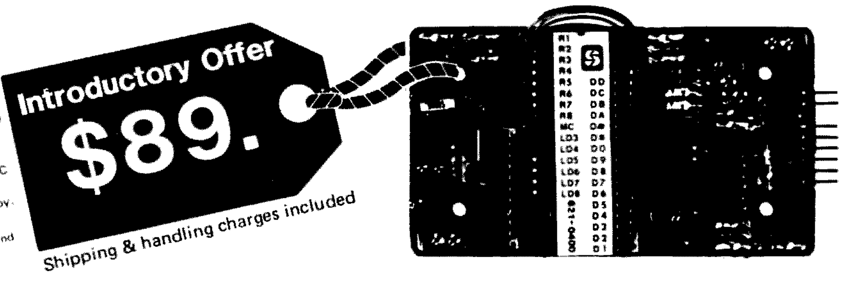
SPEEDCALL'S NEW #312 TOUCH-TONE DECODER ENDS RADIO BACKGROUND "CHATTER" FOREVER.

Output: Single open collector output, 200mA
Input Signal Range: 20 mV to 6 V (flat input)
Code Capacity: 3 to 8 digits address plus select any of the 16 touch-tone digits as desired.
Battery Voltage: 13.8 VDC Nom. (9 to 16 VDC) @ 30 mA nominal on standby.
Assembled Dimensions: 3/4" high, 2 1/8" wide and 3-3/4" long.



- **LOW COST COMMERCIAL GRADE KIT!**
- **EASY TO ASSEMBLE COMPACT UNIT!**
- **STATE-OF-THE-ART FLEXIBILITY!**

Speedcall Corporation, with 20 years of reliability and know-how in the Mobile Radio Industry, now offers the Model 312K; a unique, low-cost DTMF selective call Touch-Tone® Decoder. It's specially designed in kit form for radio buffs, with all of the quality and performance that made Speedcall #1 in signaling!

No more annoying background chatter, no more missed calls. At last it's possible for individuals and repeater groups to have their own personal and emergency touch-tone DTMF network! And you may use all 16 touch-tone digits to expand your selection of formats and permit special control applications.

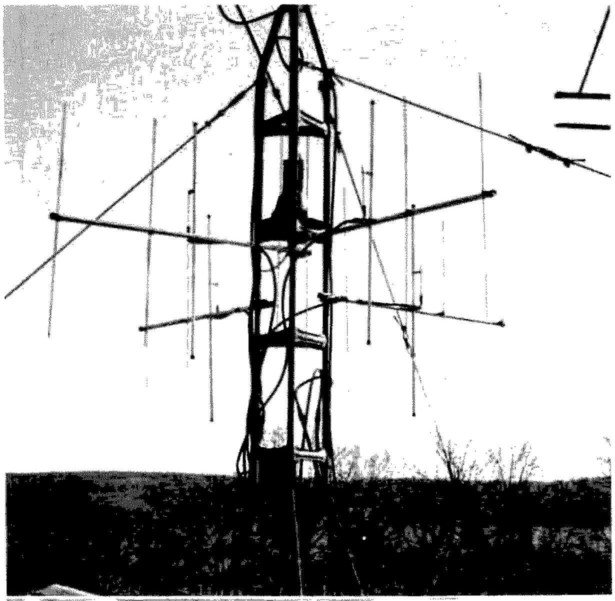
Build Yourself A Paralyzed Beam

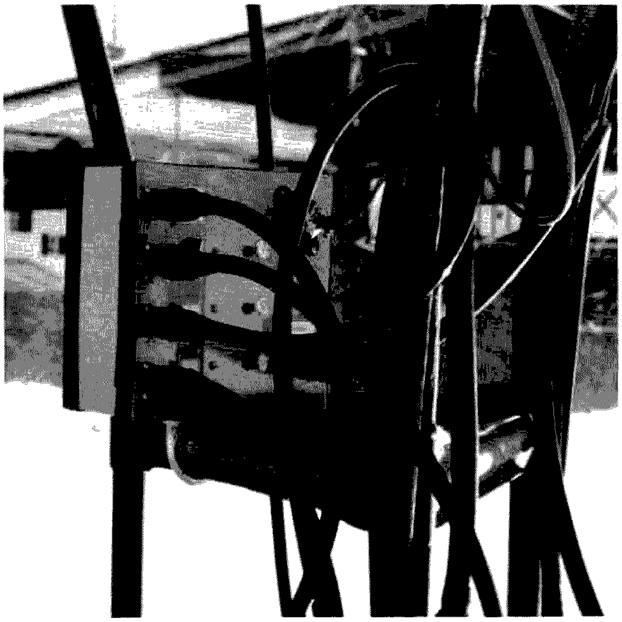
Go from east to west in less than a second with this 2-meter array. And put your rotator out to pasture.

"Five-nine here in Northern New Jersey, OM. 73 and thanks for the point. Anyone else calling?" Bzzz, whoosh "three" sputter, bzzz, whrrr. "Oh, gosh . . . the W3 calling, you're in the noise here, but you're off the back of the beam; I'll start turning in your direction . . ." Click, click, click . . . 30 seconds later . . . click, click, click. "OK, now the W3 who was calling, are you still there? Try again now."

What a waste of time to be constantly turning beams during a VHF contest. Especially on FM, where a good operator in the metropolitan area can run 60 or more contacts per hour on 146.52 MHz or other popular simplex channel, if only he doesn't have to spend half his time turning a beam. But in a densely-populated area (and there are many such regions in the US) one simply cannot use an omnidirectional



The four A147-4 beams installed on the tower.



The relay box mounted on the tower. Note the well-taped PL-259s.

gain array, due to high QRM levels. What to do? Thought you'd never ask.

How about four vertical yagis, aimed at compass points or areas of known activity, side-mounted on your tower or mast, with remote switching from a single feedline? Too expensive? Not really. Cumbersome? Not as much as a rotator. Tricky? Not at all. Simple, in fact, and requiring little time or homebrewing expertise. And the benefits are attractive, not only to the VHF contester, but to any active FMer; of course, the principle described lends itself to a variety of other interesting applications, such as diversity reception experiments or phasing of HF steerable arrays.

Personally, I used four Cushcraft A147-4 short-boom 4-element 146-MHz yagis, for their ease of matching to an unknown line impedance, light weight, and low cost. If all the control box parts listed in the parts list are purchased new at list prices per the 1980 Allied Electronic catalog and added to the *73* advertisers' prices for the coax and antennas listed, the total cost of this entire project is $159.88. The only additional expense would be the feedline (hardline sells for 49¢ per foot from several *73* advertisers), the hardline connectors (brand new for $8.00 each from Phelps-Dodge, or available for much less at flea markets), and the 4-conductor control cable (the Belden cable listed sells for $12.00 per 100' list price).

Sound like a lot of dough? I agree; that's why I bought most of the stuff (except for the antennas) at local surplus stores, which brought the cost of this project down to less than sixty bucks (minus antennas). The Cushcraft antennas specified sell for $21.00 each, but could be replaced with home-brew antennas—either yagis or quagis—for a fraction of that.

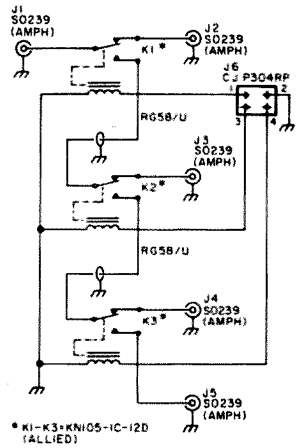


Fig. 1. Relay box.

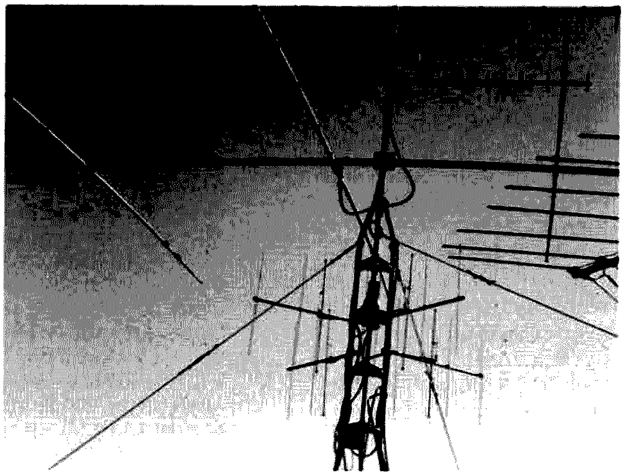
The A147-4s were selected here because they are small and light, they are end-mount types ideal for direct tower mounting, and they develop slightly over 6 dB gain, which is a tad more than my omnidirectional Phelps-Dodge Stationmaster. The Stationmaster, a well-respected, 20-foot-long fiberglass monster, sells for about $240.00; my 4-beam system works as well, and offers the advantage of selectable directivity for QRM reduction . . . and it costs far less.

See Fig. 1 for the circuit of the relay box and Fig. 2 for the control box. Real Novice stuff. Mount K_1, K_2, and K_3 in a line on one flat, removable panel of the Bud AU-1029 cabinet. Mount the four output SO239 connectors in a line parallel to and about an inch away from the relays. Mount the SO239 "common" or "input" connector an inch from K_1, on the opposite side of the relay from the four output connectors. Mount the Cinch Jones P304RP connector in whatever space is left on the same panel. Now all components and all wiring are on just one flat aluminum panel. The rest of the utility cabinet is only a weatherproof box for the relays.



Here you can see the company the four A147-4s have: 4 el on 20, 15, and 10 meters; 19 el on 70 cm; 16 el on 2 meters. Guys are broken up with ceramic insulators.

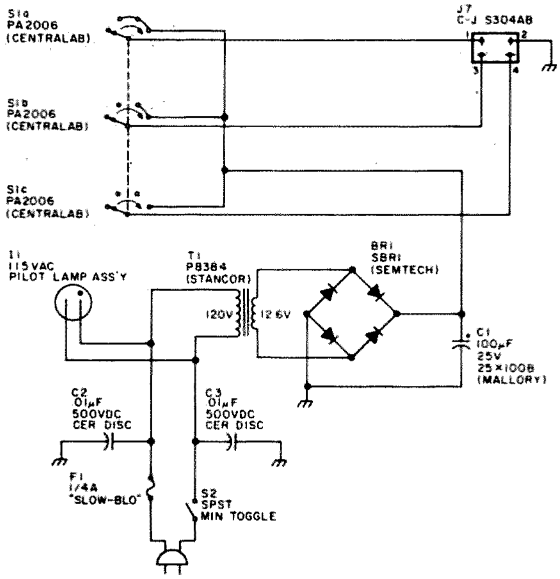


Fig. 2. Control box.

Use the flattened braid from RG-58/U for the connections from each UHF receptacle to each corresponding relay terminal, per the schematic in Fig. 1. Keep these braid jumpers as short as possible—mine are about one inch long each. If this box is intended for use at 146 MHz, this is important. Use short lengths of RG-58/U to make the K_1-to-K_2 and K_2-to-K_3 jumpers (see Fig. 1), keeping all exposed leads short. Solder the RG-58/U braid to ground lugs installed near each relay for this purpose.

The three relay coils must operate independently but they can have a common ground: thus, the wiring shown and the four-pin connectors.

After all the wiring in both the relay and control boxes is completed and double-checked, make up a short 4-conductor cable with the appropriate Cinch Jones connector at each end, and bench-test the two

units together. The dc output from the bridge rectifier should measure slightly over 17 volts with the rotary switch in position 1 (no load). This will drop to less than 17 volts with the switch in position 2, and then to about 16 volts in positions 3 and 4. The 12-volt relays specified seem to handle the slight overvoltage (and resultant overcurrent) just fine—their coils do not get hot even after hours of applied voltage. The maximum power dissipated in each relay coil is about 1.8 Watts.

Before the final installation of the relay box, drill two holes through one side of the box for a suitable U-bolt to clamp the box to your tower leg or mast. Then assemble the box on the tower or mast and caulk all corners and joints with the specified silicone caulking compound. I also wrapped the corners with Scotch 33 vinyl electrical tape.

The relay box provides a nice low vswr through about 50 MHz, but at 146 MHz it does not. Using my Bird model 43 wattmeter, a range 25C slug, a Dielectric Communications model 4050 50-Ohm, 50-Watt microwave dummy load, and a 146-MHz, 25-Watt transmitter, I measured the vswr looking into the box (with each output terminated in the 50-Ohm load) and found it to be less than 1.5:1 in position 1, but over 2:1 in the other three positions. However, there was no actual *loss* through the relays, just an impedance mismatch. What to do? Simple; tune the antennas to match the box!

Here's what to do to make it all work well at 146 MHz:

● Connect each antenna, once mounted in its permanent position, to its respective port on the box, using the 64" RG-8/U foam cables and PL259 connectors. The 64" is a nice length because it reaches, and also because it is one wavelength (in foam cable) at 146 MHz, thus making the box think the antenna is coupled directly to it.

● Connect the control box to the relay box with a length of 4-conductor cable. Locate the control box on your roof or tower for this temporary arrangement.

● Connect a 10-to-25-Watt two-meter exciter through 50-Ohm cable (any length) to a 50-Ohm coupler (I used a Bird 43) which is connected directly (like with a double-male UHF adapter) to the "common" port of the relay box.

● Apply power to the rig and the control box. With the control box switch in position 1, transmit and measure vswr. If it's low, great. If not, adjust the gamma match on antenna 1 to bring reflected power to a minimum.

● Perform the same gamma-match adjustments on antennas 2 through 4, switching to each in turn by using the control box. It should be possible to bring the vswr of each antenna down to reasonable proportions with the gamma match provided on each A147-4.

Now the system is adjusted. Remove the wattmeter, etc. Locate the control box in the shack, run the feedline and control cables down into the shack, and you're on the air.

Voila! A really high-class antenna system in just an afternoon's work. My whole installation (pictured) took about four hours, including wrestling with the hardline. The two boxes took just one evening to assemble. It was worth it. As you can see in the picture, I do own a Stationmaster for 146-MHz FM work, and although it is an excellent antenna, it is 20' long, weighs over 25 lbs., catches a lot of wind (and ice), and cost over $200.00. The four beams are more versatile, occupy less space, work at least as well, and were far less expensive.

Now, when I hear a weak station calling, I can "turn the beam" in less than one second to pull him in. What a difference! ■

Parts List

4	lengths of RG-8/U foam coax (Belden 8214), cut 64" long each
1	length of RG-58/U, about 36" long
1	suitable length of RG-331/U (½" alumifoam "hardline") feedline
8	PL-259 UHF plugs, silver-plated (Amphenol 83-1SP)
1	Phelps-Dodge #66-654 UHF hardline connector
1	Phelps-Dodge #66-656 UHF hardline connector
5	SO239 UHF receptacles (Amphenol 83-1R)
1	Cinch Jones P304CCT, 4-conductor cable plug
1	Cinch Jones S304CCT, 4-conductor cable receptacle
1	Cinch Jones P304RP, 4-conductor recessed panel plug
1	Cinch Jones S304AB, 4-conductor flush panel receptacle
1	Bud AU-1029 utility cabinet
1	Bud SC-2133 cowl minibox
3	Allied KN105-1C-12D relays (SPDT, 12 V dc/150-Ohm coil, 10-A contact rating)
1	Stancor P8384 transformer (12.6 V c-t, 1 A)
1	Semtech SBR1 bridge rectifier (100 piv/leg, 1.5 A dc)
1	Centralab PA2006 rotary switch (3 pole, 4 position)
1	Allied #652-0503 SPST miniature toggle switch
1	Mallory 25X100B electrolytic capacitor (100 μF, 25 W V dc)

Miscellaneous: #4-40 and #6-32 hardware and solder lugs; knob for rotary switch; pilot lamp assembly, 120 V ac; zip-cord/ac line plug assembly; GE silicone bathtub caulk, waterproof; terminal strips; grommet for ac line cord; hookup wire.

Note: None of the parts listed is particularly critical, and each may be substituted for as desired. However, I strongly recommend the following:

● Use only Amphenol rf connectors. Cheap substitutes may work at low frequencies, but at 146 MHz, PL-259s are marginal performers unless they're good ones and assembled properly.

● Use Cinch Jones 4-conductor plugs and sockets. They're easier to work with and are far more durable than cheap substitutes.

● Use Belden 8214, Times FM-8, or other high-quality, foam-dielectric cable for antenna/relay-box interconnects. Avoid CB-grade coax.

● If you cannot find truly high-quality foam coax, use Belden 8237 or any brand MIL-Spec RG-8/U cable (be sure the cable says "MIL" or "MIL-C-17" right on it) and change the length from 64" each to 53" each.

● *Do* use hardline as transmission line if your run to the shack is more than 50 feet. The difference in loss at 146 MHz is well worth the slightly higher cost. Why use a gain antenna system if that gain is thrown away in the feedline?

● The relays listed are somewhat critical. Avoid miniature and encapsulated relays; also avoid the plug-in type. Usually, the built-in interconnect leads are far too long for rf work, especially at VHF.

Taming the 2-Meter Linear

It lives in the forests of spurious oscillations and answers to the call of the correct bias. Catch one for yourself.

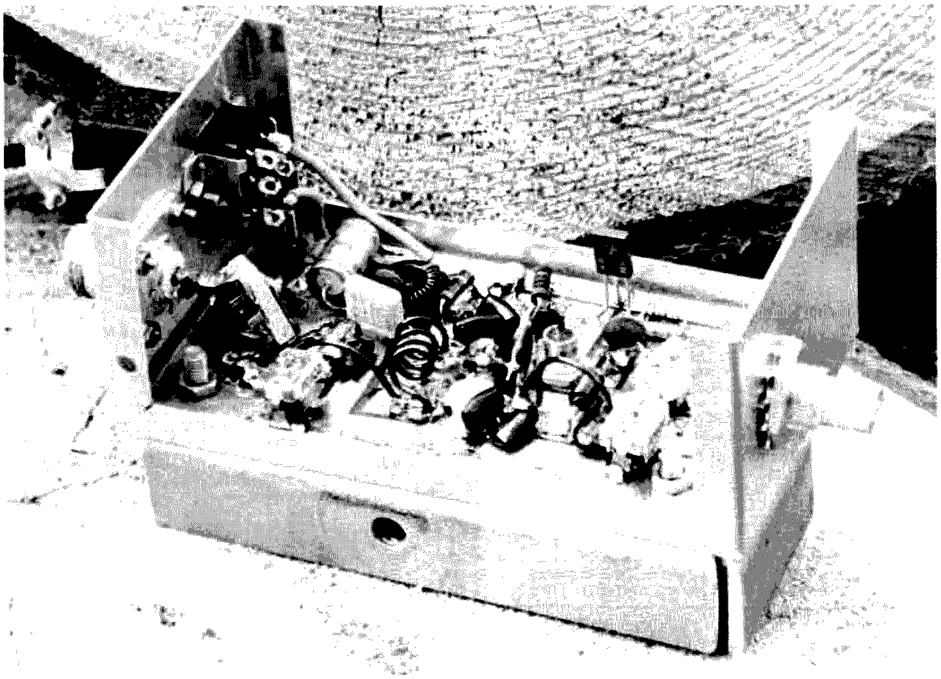
Class C amplifiers for the two-meter band are a "dime a dozen," with commercial models, kits, and schematics available from a good number of suppliers. Linear amplifiers are another story. Their design and construction is all black magic, and manufacturers are the only wizards in on the mystery. With a little sleuthing, I found that Motorola would sponsor my initiation into this exclusive cult, allowing me to build an amplifier to boost the output of my 2-meter OSCAR station from 2.5 Watts to 20 Watts.

In order to linearize a solid-state rf power amplifier, you must solve two problems. First, you must bias the transistor into the linear region while supplying a substantial amount of varying base current. Secondly, you must tame any spurious oscillations generated by the high-gain transistor used.

First, the biasing problem will be faced. A small-signal transistor amplifier is usually biased with a voltage-dividing network such as that shown in Fig. 1(a). The current flowing through the network resistors is set to be about ten times the current needed by the base. With our amplifier needing from 10 mA to 100 mA of base current at any time, this circuit would not be practical. As well, the bias voltage must be held at a constant stiff value for all values of base current, which is not possible with a resistive voltage-divider network.

An alternate solution to this biasing problem, which satisfies the need for a constant bias voltage while supplying varying currents, is the solid-state voltage regulator. Either the shunt regulator of Fig. 1(b), where the total bias supply current is greater than the maximum base current and the surplus current is shunted to ground by the reference diode, or the series pass regulator of Fig. 1(c) can be used. The series regulator reduces the current which must flow through the reference diode by i_{base}/hfe, and the total bias current used becomes virtually the base current needed at each instant. The bias voltage is set by the forward voltage drop of the diode reference which is approximately 0.6 volts. The series regulator bias is set by two forward-biased diodes in series, the second diode voltage drop compensating for the base-emitter junction drop of the series pass transistor so that the bias supply voltage output will equal only one PN junction voltage drop.

Now for a very important point! As a transistor warms, its base will draw more current, which increases collector current, which warms the transistor more, and this will continue until the component self-destructs. To offset this, the base bias voltage must be reduced as the transistor warms. By mounting D_{ref} as



MRF 2-meter linear amplifier.

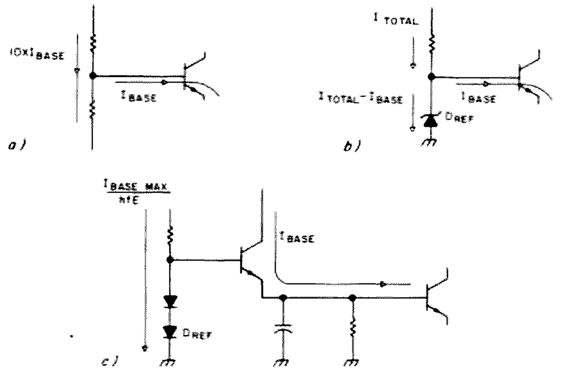


Fig. 1. Bias possibilities. (a) Voltage divider arrangement. (b) Zener diode stabilized. (c) Pass transistor circuit.

close to the rf transistor as possible to provide thermal contact, the diode junction voltage will *decrease* as the diode warms, neutralizing the base-emitter junction change of the rf transistor and thus keeping the base current under control. Remember! Attach the reference diode so that it will be warmed by the rf power transistor. Either physically attach it to the transistor body or to the heat sink as close to the transistor as possible. *Do not* expect the reference diode to thermally track if the thermal path is broken by air.

Low-frequency oscillations also are a problem. My amplifier first oscillated in the HF band because at these frequencies the transistor has very high gain. Bypassing the collector current feed did not tame these troublsome responses, so I took the brute-force method and fed back the collector signals to the base through a feedback network. The rf choke is a virtual short for the oscillations but an open circuit for the desired VHF response. The capacitor is a virtual short for the undesired oscillation but an open circuit for the collector supply. This network was placed between the collector and base with very short leads and the unwanted oscillations were completely suppressed.

The amplifier which I built (Fig. 2) is a modified version of the class C amplifier described by W4MNW in the November, 1977, issue of *73 Magazine*. I lifted RFC1 from ground, added bypass capacitors to the lifted end so the rf input would continue to see a ground, then connected the base bias supply to RFC1. The low-frequency feedback network was added to stabilize the amplifier and the linear amplifier was a reality. It would appear to be quite possible to linearize many of the class C amplifiers now in FM and CW use in the same way.

The testing of this amplifier was done with a regulated and current-limited power supply. This saved the transistor from destruction before I had tamed the low-frequency oscillations. The transistor is rated for a collector current of four Amperes, but I set the supply to limit current to a maximum of one Ampere until I was satisfied that the amplifier would not hurt itself.

Low-frequency oscillations manifest themselves by a sudden jump in collector current and corresponding drop in supply voltage. The first time this happened I thought I had destroyed the transistor, but the power supply protection had saved it. I was able to continue my study of the problem and a wideband oscilloscope revealed a pulse-type response on the collector output. This was suppressed by the feedback network shown in the schematic.

I made an interesting observation about amplifier efficiency while tuning the amplifier. There is a particular collector current needed to give a particular output power—not so collector voltage. Thus 0.5 Watts input will become 4 Watts output at 2 Amperes collector current whether the collector voltage is 5 or 12 volts. Under the same conditions, the dc input power changes from 10 Watts to 24 Watts. For maximum efficiency, it seems that the amplifier should be operated at the maximum linear power output possible for the applied collector voltage, or if it is desired to operate the amplifier at reduced power, the collector voltage should be re-

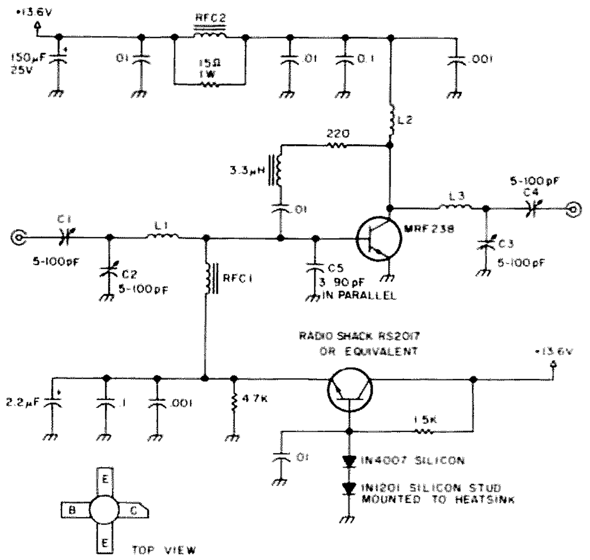

Fig. 2. Amplifier schematic.

Coil Construction Details

RFC1 10 turns #22 on 270-Ohm, ½-Watt resistor
RFC2 13 turns #22 on T50-6 toroidal core
L1 ½ turn #16, approx. 1½"
L2 4 turns #16, 1/4" i.d.
L3 Curved wire, #16, 1-1/4" long

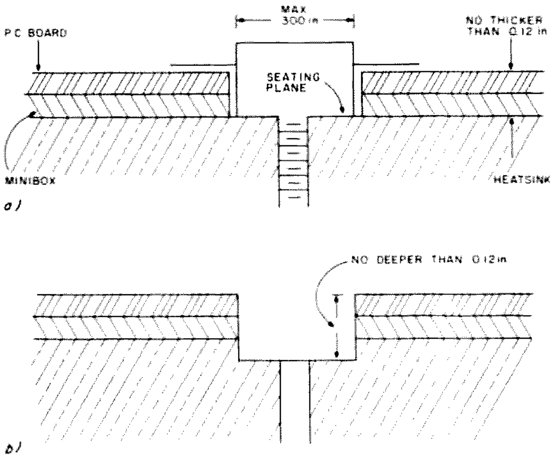

Fig. 4. MRF238 mounting details.

duced. Linear operation at 4-Ampere dc input is shown in Fig. 3.

The amplifier was built in a 5¼″ × 3″ × 2½″ minibox on double-sided epoxy glass PC board. The circuit lands were etched, but islands of PC board epoxied to the ground plane would serve as well. Be very certain that the capacitors that make up C5 are soldered with *short* leads as close to the transistor body as possible. Connect the ground plane on both sides of the board with eyelets or wire running through the board and solder on each side. A heat sink is necessary. My heat sink has 35 square inches of radiating area and it seems to be just satisfactory. A larger one is recommended.

The mounting of the MRF238 is very critical (see Fig. 4). Careless technique will result in a destroyed transistor if stress is placed on the leads. Mount the transistor seating plane with very good thermal contact to the heat sink. The thickness of the case metal and the PC board must not be greater than .120 inch. If it is, the transistor leads will be forced up, putting a strain on the transistor cap. On heating, the bonding material will fail and you will be out buying a new expensive transistor. If the PC board and case thickness together is much less than .120 inch, you may want to mill out the heat sink as in Fig. 4(b) so the transistor leads will not be bent down when soldered to the PC board. *Do not* solder the leads before tightening the stud mounting nut. *Do not* hold the transistor leads while tightening the nut. *Do* hold the transistor securely by the wrench flat on the end of the stud while tightening the nut. Only after the mounting nut has been tightened carefully may you solder the leads to the board.

The MRF238 Motorola transistor is available from Ramsey Electronics and Semiconductor Surplus, both *73* advertisers. ■

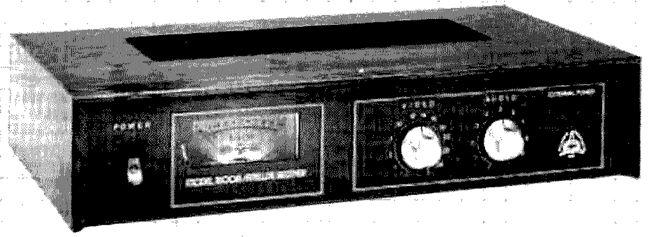
Gillaspie

The Model 7600A



The Model 7600A Satellite Receiver is the new look from Gillaspie. State of the art technology. Distinctively styled. The successful integration of the most sought after high performance characteristics and ease of operation capabilities. Attractively packaged. Affordably priced. A classic in its own time. From Gillaspie, of course.

- FULL FREQUENCY tunable audio
- Reception 3700 to 4200 MHz
- Built-in video modulator
- Simplified channel tuning
- Improved video sensitivity
- All wood cabinet

The Model 7600A Satellite Receiver System Package comes with its antenna mounted Image Reject Mixer (Down Converter), built-in video modulator, 100′ of RG59-U cable and 100′ of Belden DC cable with connectors installed.

Gillaspie & Associates

The Frugal Floppy Bazooka

This 2-meter antenna coils up into a small package, but it shoots a straight signal.

Another 2-meter antenna for your handie-talkie? You bet! When you combine low cost, portability, and reasonable gain as this antenna does, it is well worth covering the subject again. The design of this gain vertical was inspired by the excellent article by W1IS in the May, 1981, issue of *73 Magazine*. One of the current-distribution charts reminded me of the "bazooka" coax-to-dipole decoupling scheme which uses a grounded sleeve in place of radials, and the "floppy bazooka" was born.

Construction

My prototype antenna was assembled from RG-58A/U (with the stranded center conductor), which is (a) very flexible and (b) what I had on hand. I started with about 20 feet of the cable and terminated one end with a BNC male to match the connector on my HT. The next step is to remove approximately 34 inches of the outer cover and braid from the loose end of the coax, leaving about ¼ inch of braid exposed and the center conductor intact.

Why 34 inches if a quarter wave at 146 MHz is about 19 inches? Because I had to compress the braid slightly, increasing its diameter and decreasing its length, to slide it over the feedline. After doing so, I *carefully* soldered the ¼ inch of exposed braid on the feedline to the braid sleeve, taking care to not melt the center conductor dielectric. I provided as much coverage as possible with the braid splice.

I covered the splice with heat-shrink tubing, although electrician's tape will do fine. Pull the braid down snug on the feedline and *now* measure the 19½ inches you expected, from the splice just covered to the lower end of the sleeve. I found this dimension to be very noncritical, but the shortening with compression varied from sample to sample of coax, which is why I started with 34 inches! After cutting the sleeve to length, I secured the end to the feedline in the same way I covered the splice.

Testing

The *first* test I made was with an ohmmeter: checking at the BNC end for a potential short. Don't trust the ability to receive a full-quieting signal as proof of proper wiring—I live less than a mile from a local repeater, which breaks the squelch on my HT fine without any antenna plugged in at all!

After avoiding the "smoke test," it was time to prune that 34-inch center conductor to resonance. My first cut was to 20½ inches, and out came the swr bridge. One quarter of an inch at a time, I marched up the band—on low power and avoiding repeater inputs, of course. I found that the antenna would give better than a 2:1 swr over about a 1.5-MHz range,

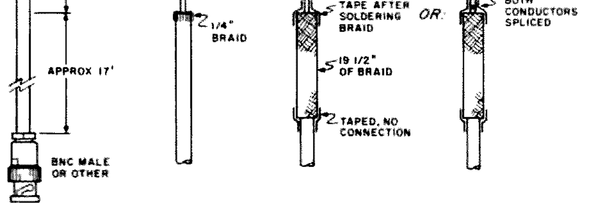

Fig. 1. The floppy bazooka.

with 19¼ inches hitting 146 MHz on the nose.

I wasn't thrilled with that bandwidth, so I opted for a simple modification: a "thicker" radiator. I started with a 20-inch piece of RG-174/U, with the center conductor and braid shorted together where they are spliced to the center conductor of the RG-58A/U and shrink tubing again covering the evidence. After the same pruning procedure, this came much closer to my expectations, covering the entire 144–148-MHz band with a worst-case swr of 1.8:1.

Use

I attached some 1/8-inch nylon cord to the top of the center conductor with two small wire ties, and the installation problem of a non-self-supporting antenna was solved. The antenna can now be suspended almost anywhere. Bear in mind that it has a very low angle of radiation and must be kept quite vertical to take advantage of its gain characteristics. I chose the 17-foot length of feedline as a reasonable trade-off between losses and the ability to put the antenna in better (higher) places. The antenna and nylon "mount" bundle neatly into a tiny package hardly larger than my HT, making it an ideal traveler's antenna.

My comparison of the floppy bazooka's performance to other antennas was not rigorous, but very satisfying. It significantly outperformed my ¼-wave ground plane in fixed-station use and incredibly outperformed the rubber ducky.

The floppy bazooka is cheap, easy to build, and works very well. It also lends itself well to modification and experimentation. Try it! ■

COMMUNICATIONS DIVISION

(We Speak Your Language.)

Backed by over 54 years of experience, Harvey continues to offer the broadest selection and finest service available for the amateur radio community. This experience has taught us that the ham needs special treatment and that is why Harvey has established a special division dedicated to the needs of the U.S. and foreign ham alike.

One thing is for certain. A ham will never get the run around from Harvey. If we don't have something in stock, we say so and will order it for you—or—tell you where to get it. However, we are sincerely dedicated to the ham community and, as a result, our expansive inventory means that, more than likely, we will have what you are looking for *in stock*.

Taking It Higher

Raising a repeater's antenna is the way to wider coverage, right? Wrong.

When it comes to repeaters, higher is better! Right?

Not necessarily. It depends on what you want to accomplish.

Sooner or later, every repeater organization in the country gets the urge to move the repeater antenna up to twice as high as it already is, to improve coverage. Most of the time, it does improve. Every once in a while, though, some unexpected glitches result.

The Tallahassee Amateur Radio Society went through the process of moving from a downtown site with an antenna elevation of about 350 feet to a new commercial tower near the edge of town with an elevation of 800 feet above mean sea level (MSL). Sure enough, coverage was considerably extended. But sure enough, there were several surprising developments. What happened, and why, makes an interesting case study.

We knew from experience that the downtown site gave us an effective coverage range of about thirty miles in all directions over fairly mild terrain. South of the city, the coastal plain stretches away to the Gulf of Mexico, flat as a pizza, with an elevation of about 50 feet above MSL. But right in the middle of the city the terrain rises abruptly at the limestone scarp which, a few million years ago, was the coastline when sea levels were higher than now. These hills rise to elevations of 150 to 230 feet, with an average elevation of perhaps 175 to 200 feet above MSL on any bearing in the northern semicircle centered on Tallahassee.

What would happen when we moved from 350 feet to 800 feet? Would we be able to work 75 miles? 100 miles, as some members predicted?

The visual line-of-sight distance from an antenna to the horizon is expressed by the formula $R=\sqrt{2H}$, where R is the range (or radius) in miles and H is the height in feet of the antenna above average terrain. It is the basis, in commercial antenna engineering, for computer calculations of the antenna's performance, cranking in corrections for such things as absorption of radio energy by foliage and buildings, shadowing by hills, and the fact that radio signals can nearly always be heard beyond the visual horizon.

Without benefit of a computer, I modified the formula based on empirical observations of repeater performance in actual operation. The formula is intended to be an approximation, not a precise prediction. I cranked in a number of assumptions about ham radio which do not apply to commercial and public safety services.

For example, most amateurs are willing to settle for less than 100% reliability over a given path. And most of us are willing to accept a noisy signal if it is still readable. The modified formula turned out to be: $R=\sqrt{2.5H}$.

Applied to our downtown antenna site, it predicted a contour which agreed well with our experience with the repeater. Here it must be said that a number of other assumptions also must be made. For example, we assume that most mobiles will use about 15 Watts output to a quarter-wave whip, that they will be in motion, that they will have little or no ignition interference, that they have receivers with a sensitivity of half a microvolt or less for 20 dB of quieting, and that the ambient acoustical noise in the mobile will be fairly high.

The critical parameter was defined as the point at which "practical communication" through the repeater becomes possible between a mobile at the fringe of the coverage and a mobile or fixed station located within the full-quieting contour of the repeater. In effect, this boils down to: "Can I use the repeater to get useful information on

road directions or weather conditions?"

Once the repeater was installed in the new location, I began collecting data by the simple expedient of working mobiles as they passed through the area and noting their positions when effective practical communication became impossible. Each such observation was noted on a large scale map (half an inch per mile) as a big red dot. Eventually, each of the roads into town became plastered with dots which sometimes covered several miles of road. These "smeared" observation points resulted from the variations between observations. One mobile might be using 25 Watts to a 5/8-wave whip. The next might be running only 10 Watts to a quarter wave. Another might suffer severe ignition noise on reception or his receiver might be "hot" or slightly "deaf." Propagation conditions might exert some influence from day to day. The final point on the road was chosen at about the middle of the "smear."

The results of the tests were plotted on a map, with the observation points on the highways being connected by a smoothed line. Circles, also centered on the repeater site, showed the 40- and 50-mile radii. The formula predicted an effective working range of 44 miles, disregarding terrain effects.

The interesting distortions of the working contour are almost entirely the result of terrain. A peculiar flattening in the northwest quadrant results from a ridge of hills along the eastern bank of the Apalachicola River. Mobile signals almost "wink out" when they drop over the crest of the hill into the river flood plain. The southern semicircle bulges outward because the terrain in that sector is substantially lower than Tallahassee and is dead flat coastal plain. The Gulf coast itself cuts off the bottom of what would be a rough circle. No observations were taken from boats in the Gulf. I suspect that the contour would bulge outward in that sector because of the high conductivity of the salt-water ground.

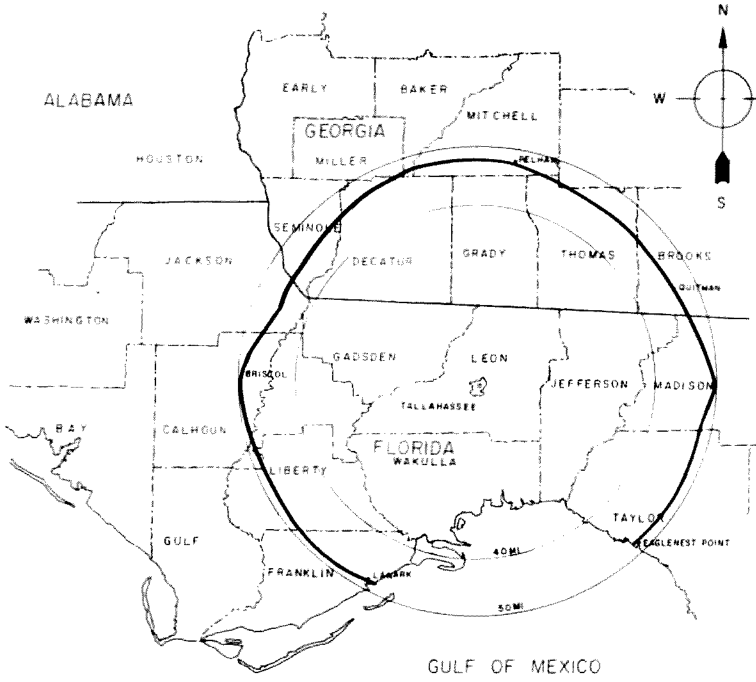

Fig. 1.

One unexpected side effect is that the repeater signal in the city of Tallahassee is not strong enough to quiet fully most mobile receivers. A possible reason is that the antenna is designed to provide some gain and it does this by taking energy away from the upper and lower hemispheres of the radiation pattern and concentrating it around the "equator." The antenna is so high that most of the city lies in the deprived cone directly below it. The favored lobe of radiation widens gradually as it goes away from the tower, and at 10 miles or so the signal at ground level is quite strong.

Another unexpected problem arose in early work at the new site. We tried to use the top antenna at 800 feet for receiving and a side-mounted antenna at 485 feet for transmitting. Reflections and other effects resulting from the tower, guy cables, and other factors produced a radiation pattern which was pulled in strongly to the west and had a powerful lobe to the northeast with an effective range of nearly one hundred miles in the favored direction. We solved the problem by using the top omni antenna for both transmit and receive.

The repeater is on 146.31/.91 MHz, and in this area we have very little, if any, co-channel interference unless there's a strong band opening. For a few days, we experimented with a 146.16/.76 machine on that tower. The results illustrate one of the problems which go along with great height. Mobiles trying to bring up the Valdosta, Georgia, repeater on .16/.76 eighty miles away also brought up the Tallahasee repeater. And because of the strong northeast lobe, our signal was nearly as strong in Valdosta as the Valdosta signal was!

In urban areas, it is entirely possible to cover so large a ham population that the traffic load on a repeater becomes unacceptably high unless access is restricted in some way. When contemplating a repeater on a tower at 2,000 or 3,000 feet above average terrain, it may be desirable to choose a site considerably distant from any expected concentration of ham stations. Otherwise, the area deprived of signal by the antenna gain effect may become a real problem. The effect is greater on UHF than on VHF.

The Stone Mountain repeater near Atlanta, for example, covers Atlanta and most of the surrounding country like a blanket, but it is located about twenty miles east of the city itself. Repeaters located in the Great Smoky Mountains of Kentucky, Tennessee, and northern Georgia cover enormous ranges in their favored directions (where

mountainous terrain doesn't block the signals) and they serve a largely rural population without the dense concentration of stations which might cause problems in, say, New York City, Chicago, or Los Angeles.

It should be kept in mind, when trying to apply our rule-of-thumb range formula to other locations, that terrain is often a much bigger factor than it is in Tallahassee. The formula will give reasonably accurate results only when it is applied to one particular radius using the "average terrain elevation" along that particular line. A repeater in Iowa may well have an almost circular pattern. A repeater located in California or West Virginia is likely to be a totally different matter. The formula is not applicable directly to repeaters on bands other than two meters because terrain losses will not be the same. However, on any band, range will vary in direct proportion to the square root of the height of the antenna, and it should not be difficult to work out a new H multiplier which would give reasonably accurate results on, say, 50, 220, or 450 MHz.

Clubs which put up repeaters with wide coverage areas should be prepared to welcome and to serve many itinerant mobiles travelling through the area who may frequently be more interested in working each other than in working locals. Repeater groups that want to communicate among themselves for rag-chew, emergency, or other purely local communications purposes should give serious consideration to using a lower antenna site or a closed repeater operation using some form of restricted access. ■

Dial-A-Frequency

Let your fingers do the walking with this remote control. All you need is a spare telephone.

Have you ever had a need to remote control a multi-channel radio over a distance but didn't want to run a multi-conductor cable? I have a Heathkit® HW-202 two-meter radio that is located in my shop which is in a barn about 150 feet from the house. I wanted to be able to use the radio in both the barn and the house without moving it. One solution to this problem is described here.

The system I developed allows me to dial up any one of four channels in my two-meter radio. This is done using a standard dial telephone with a minor modification for push-to-talk operation. The telephone is connected to a controller via a single pair of wires that can be several hundred feet long. Several phones may be connected to the line, although only one may be used at a time. Of course, the telephone may be moved about by using jacks.

I'll review a little of telephone basics, go into the development of the system, talk about construction details and adjustments, and offer some afterthoughts that you may want to include in your version. Successful duplication of the ideas presented depends on how resourceful you are, as some of the relays and transformers may be difficult to find.

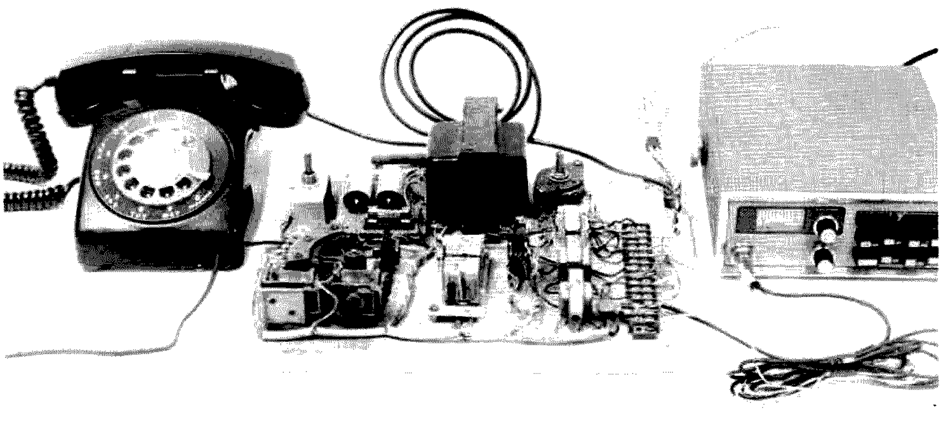

Photo A. Overall view of the remote two-meter dial-up system. The telephone can be located several hundred feet away from the radio and its controller.

Basic Terminology

We all use the telephone every day. It seems to be a simple enough device, and on close inspection, it is. Fig. 1 shows the basic circuit from the telephone to the central office. The two wires that connect these two locations are a twisted, balanced pair with a typical characteristic impedance of 600 Ohms. Longitudinal balance describes how closely each conductor matches the other along the

route. This becomes increasingly important the longer the circuit becomes. The better the longitudinal balance, the less interference occurs from outside sources such as other telephone circuits in the same cable and parallel power conductors.

The telephone set shown in Fig. 1 is a simplified circuit. An actual type-500 phone as shown in Photo C has additional circuits to match the impedance of the set to the line and has additional contacts on the dial and the switch hook to short out the earphone when dialing or when the receiver is on hook. This eliminates annoying pops in the earphone.

Direct current continuity is a requirement of the circuit for signaling and to provide a dc bias current for the carbon microphone in the telephone. When you lift the telephone "off hook," the dc circuit is completed with current flowing through the microphone. When you turn the dial clockwise to the stop, a spring is wound up in the dial. When the dial is released, the spring returns the dial and a set of contacts opens and closes once for each digit dialed at a rate of 10 pulses per second. Many modern central offices can respond to 20 pulses per second, so some phones are so equipped. A tone-dial phone still requires a dc continuous circuit to tell the central office when it is off hook and to have dc bias for the carbon microphone and tone generating circuits.

At the central end of the circuit, note the one-to-one ratio transformer with a split winding on one side. This transformer allows the insertion of dc current and the picking off of the control signals while maintaining the circuit balance to ground. At the same time, voice and tone signaling (if applicable) are coupled through to the other side of the transformer. The capacitor shunting the power supply and relay coil on the line side of the transformer bypasses audio frequencies.

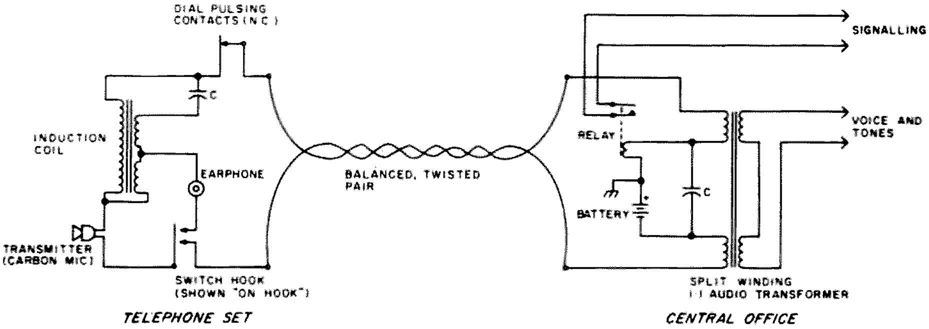

Fig. 1. Basic telephone circuit. Note that dc current flows from the central office battery through the carbon microphone—but only when the switch is "off hook."

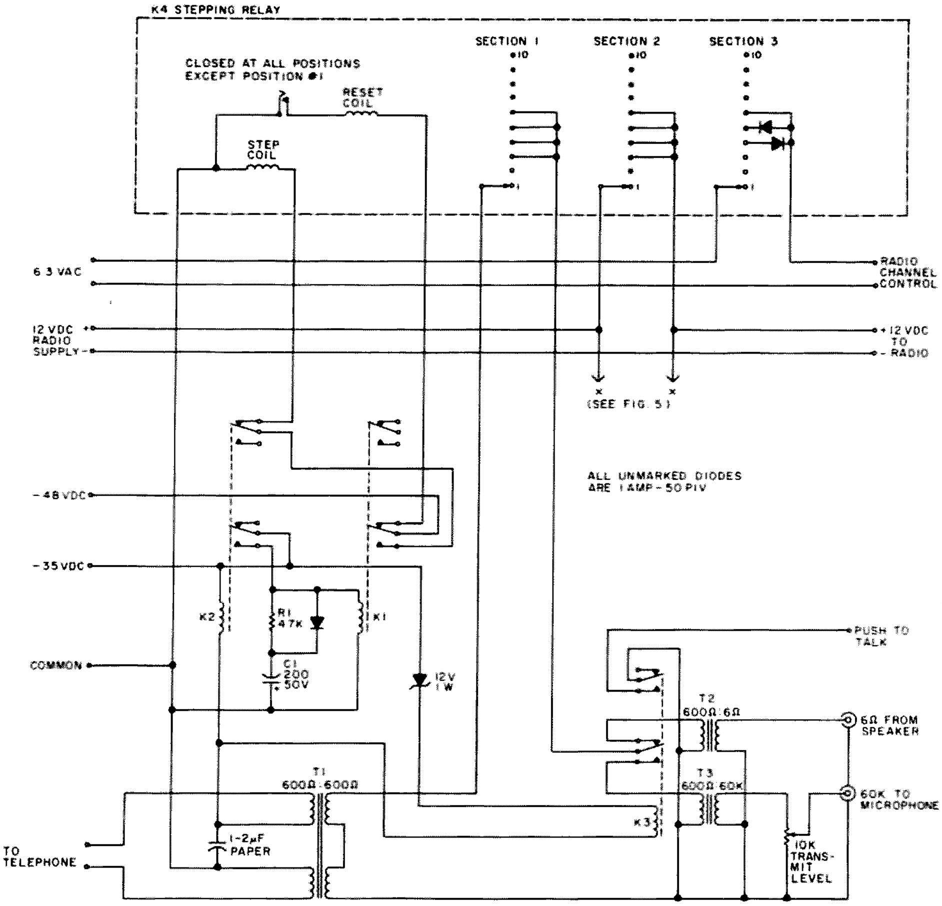

Fig. 2. Schematic diagram of the dial-up two-meter remote controller.

The circuit shown in Fig. 1 is the basis of my two-meter dial-up remote controller. I won't go further into the operation of the central office, but if anyone is interested in further study in this area, *Basic Telephone Switching Systems* by David Talley (Hayden Book Company, New York NY) makes good reading.

Development of the Dial-Up Remote

There are three control functions that must be provided in the two-meter dial-up system: the off-hook condition, dial pulses, and push-to-talk function. These three functions are provided by relays K1, K2, and K3, respectively, in Fig. 2. The telephone set itself must be modified to provide push-to-talk operation. More about this later.

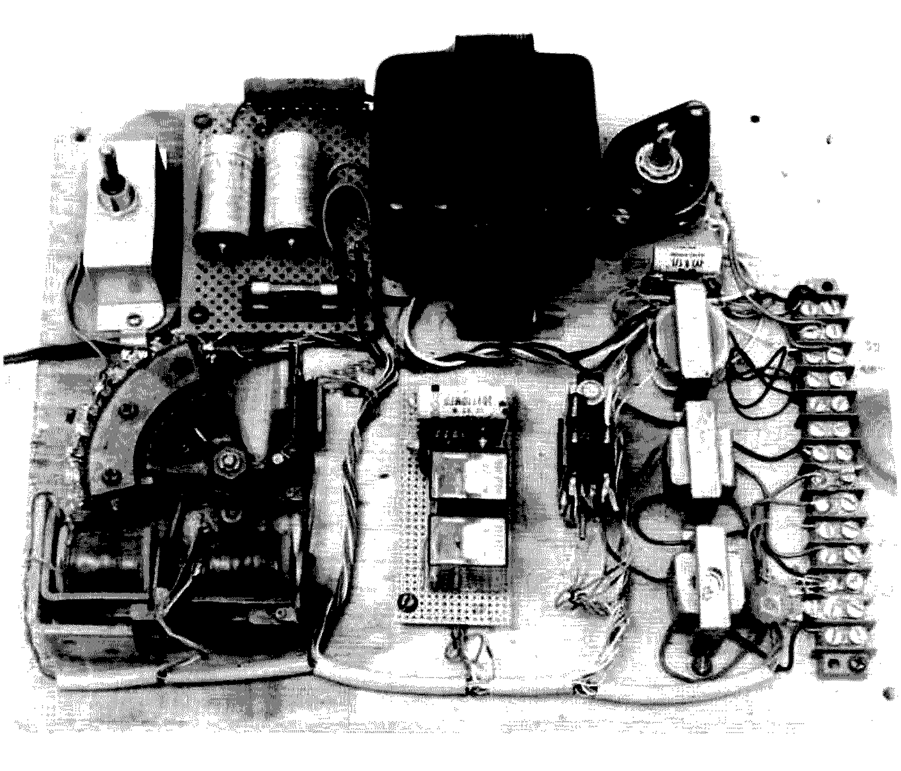

Photo B. The controller with power supply at the rear, stepping relay at the left, K1, K2, and K3 in the middle, and the audio transformers next to the terminal strip on the right.

When the telephone receiver is lifted off hook, the dc circuit is completed from the 35-volt source to K2 and to the series combination of the 12-volt zener diode and K3. Contacts on K2 apply 35 volts to K1 and charge C1 through R1. R1 is necessary to prevent contact arcing on K2. Now that K1 is picked up, the 48-volt source is removed from the reset coil on the stepping relay and applied to contacts on K2 which are connected to the stepping coil. A separate 48-volt source was necessary because of the particular stepping relay that I had available.

What happens now if the dc loop to the telephone set is broken for a fraction of a second by dialing a "1"? Relay K2 drops out for a brief period and picks up again when the dc loop is again completed. This removes the 35-volt source from K1 briefly, but the charge on C1 holds K1 closed through the diode. The 48-volt supply is therefore maintained to the contacts on K2 which close for the brief time that K2 drops out. This applies a single pulse of 48 volts to the stepping coil, advancing the switches one step to position two.

If you were to hang up at this time, relay K2 would immediately drop out. Relay K1 would remain energized for about one-half second because of the charge on C1. When K1 finally drops out, the 48-volt supply is applied to the reset coil. Because the switches are not in position one, the reset contacts on the stepping relay are closed. The reset coil will therefore reset the switches to position one, at which point the reset contacts on the stepping relay again would be open.

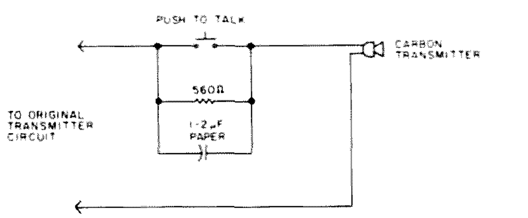

Fig. 3. Telephone set modification for push-to-talk operation.

If we now lift the receiver and dial, for example, a three, the switches will advance to position four and stay there until we hang up again. Note that the stepping and reset coils never have voltage applied for any length of time. They usually are rated for intermittent duty only. Note also that dialing 12 or 21 has the same effect as dialing a three.

Fig. 3 shows the modification for push-to-tak operation. The parallel combination of the pushbutton, resistor, and capacitor is inserted in series with the carbon microphone or at any point in the current loop, such as the line coming into the telephone. When the push-to-talk button in the handset is pressed, the 560-Ohm resistor is shorted, resulting in a higher voltage across K2 and the series combination of K3 and the zener diode. A zener diode was used in series with K3 rather than a resistor so all of the voltage difference brought about by pushing the push-to-talk button would appear across the relay. The capacitor shunts the resistor for voice frequencies.

Relay K3 must be selected carefully. It must have a drop-out voltage not much less than its pick-up voltage. The unit I used has a 12-volt coil and is a plug-in type from an old IBM keypunch machine. Most 12-volt relays will pick up at about 10 volts but many will not drop out once picked up until the voltage is less than three or four volts. The variable resistor in the power supply (Fig. 5) is adjusted for proper push-to-talk operation. You may want to experiment with electronic circuits to sense the push-to-talk voltage change and which would, in turn, drive the push-to-talk relay. Another alternative would be to run a separate pair of wires for the push-to-talk button.

The push-to-talk relay, K3, grounds the push-to-talk line to the radio and switches the 600-Ohm audio from the split-winding transformer, T1, between the radio microphone input and speaker output. Impedance matching is required on both of these circuits. I used some small, 120-to-12-volt (10:1 ratio) filament

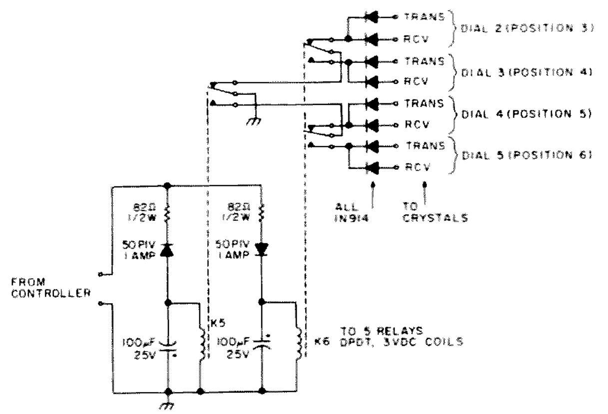

Fig. 4. Channel-change circuit located in the radio.

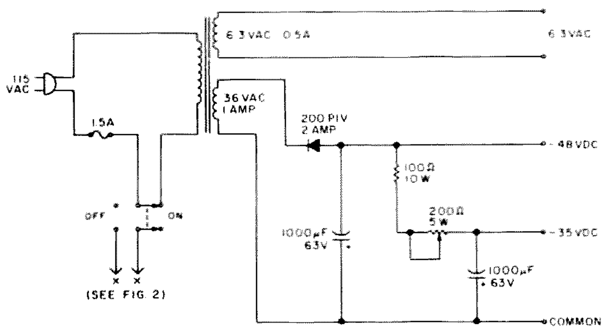

Fig. 5. Power supply schematic diagram.

transformers from my junk box.

The stepping relay that I used has three switch sections. It is a C. P. Clare model A321033 that was salvaged from an electrical circuit recloser. One section is used to connect the telephone circuit to the radio. This allows me to dial up other devices on other positions of the stepping relay, such as a weather receiver. The second section turns on the power to the two-meter transceiver. The third section changes channels in the radio. Stepping relays are available from time to time from surplus outlets such as Fair Radio Sales, 1016 East Eureka Street, PO Box 1105, Lima OH 45802.

Fig. 4 shows the channel-change circuit. Two miniature relays are used to select the appropriate crystals in the Heath HW-202. The resistors in series with the relays are necessary because the relays I had available have 3-volt coils. Note that when the stepping relay is in position three, neither relay is energized. When in position four, K6 is picked up, when in position five, K5 is picked up, and when in position six, both relays are picked up.

In each case, a different pair of crystal switching diodes is grounded. I disconnected the radio switch grounds from the chassis ground and reconnected them to be grounded when neither relay is energized, position three. This allows me to select with the radio switches which channel will be selected when dialing a two. It also allows the radio channel switches to function normally when not connected to the controller or when the controller is switched off. The other three positions are connected to the crystals of the most commonly used channels.

The power supply, Fig. 5, is straightforward. A small amount of 6.3-volt ac power is required for the channel-changing circuit. The 36-volt secondary on the transformer gives about 48 to 50 volts dc for the stepping relay. It must be capable of supplying the intermittent current requirements of the stepping relay, about 1 Ampere in my case.

Dropping resistors are used to supply a lower voltage for operation of K1, K2, and K3. This voltage should be relatively hum free as it is also used to bias the carbon microphone. The dropping resistor is made variable to allow setting the push-to-talk operating point. Positive grounds are used as this is telephone system convention but it certainly isn't necessary. If negative grounds are desired, it is only necessary to reverse the polarity of C1, the diodes associated with K1 and K3, and, of course, the power supply capaci-

Photo C. Modified telephone set. Note the push-to-talk button in the handset and the resistor-capacitor combination mounted on the added terminal strip.

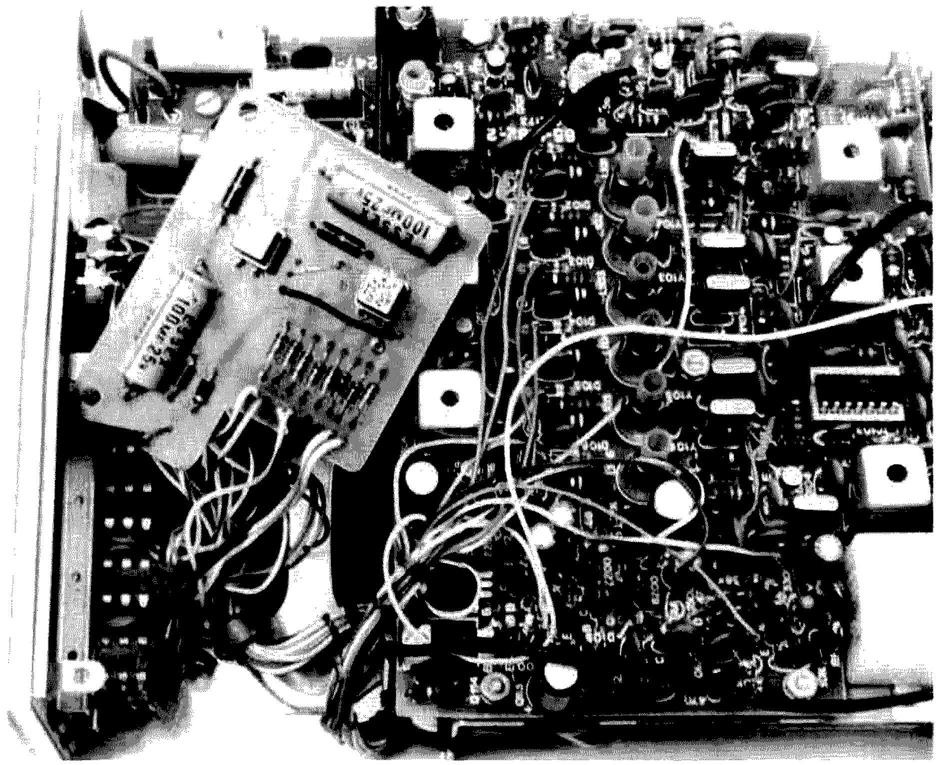

Photo D. Channel-change relay circuit board. The ungrounded side of the circuit pokes through the plastic filler where the burst encoder push-buttons would be located.

tors and diodes. Power supply requirements for other versions will probably be different depending on what relays the junk box and local surplus outlet may yield. Switch S1 turns on the power to the radio when switching the controller off so that the radio can be used in a normal fashion.

Construction

As can be seen by the photos, I mounted all components on a piece of wood. While this method of construction is simple and effective, it is not terribly attractive. I plan to reconstruct the unit in a 3″ × 10″ × 17″ chassis mounted on a 3½″ × 19″ relay rack panel. Layout is not critical.

Modification of the telephone consists of removing the bells to make room for a terminal strip on which to mount the added resistor and capacitor. See Photo C. The handset must be changed to a push-to-talk type (available from Gray-bar Supply, 345 Harrison Avenue, Boston MA 02118, and from Fair Radio Sales, previously mentioned). The resistor-capacitor-switch combination can be inserted anywhere in the dc current loop.

The channel-change relay circuit board (Photo D) was etched using a Radio Shack etch resist pen and etchant. The board is simple enough that no fancy techniques are required. Foil layout will vary depending on your radio and the relays you can find. The ungrounded side of the channel-change circuit clips to the wire poking through the plastic filler where the burst encoder would go. This can be seen in Photo A.

Cables between the controller and the radio should be only a few feet long because of the high-impedance microphone circuit. Run a separate return lead for the channel-change circuit. Otherwise, the return current will flow on the microphone cable sheath resulting in transmitted hum.

The 12-volt dc leads should be fairly heavy to carry the 2.5 Amperes or so required on transmit. The push-to-talk lead goes into the microphone connector with the microphone cable. Make the speaker connection to the remote speaker outlet and throw the speaker switch on the radio.

The connection between the telephone and the controller is a single pair of telephone wires, typically number 19. I use about 150 feet of ordinary telephone wire, but distances up to one-half mile or possibly more should work. The limiting factor will probably be getting the push-to-talk relay to operate properly due to additional resistance of the phone line.

Adjustments and Operation

The first adjustment is to set the variable resistor in the 35-volt portion of the power supply. Start by setting it for maximum resistance. Then with the push-to-talk button on the telephone pressed, decrease the resistance until K3 picks up. Note the position of the resistor shaft. Releasing the button should cause the relay to drop out. If it doesn't, the push-to-talk relay you've selected must be replaced with a different type with a higher drop-out voltage. Assuming your relay did drop out, continue decreasing the resistance while pressing and releasing the button. Note the point where the relay will no longer drop out. Set the variable resistor midway between this point and the point where the relay first picked up.

Setting the transmit level can be done several ways. The ideal way would be to use a deviation meter. Barring that, connect a VTVM set for ac to the microphone connector terminals at the radio. Note the level range for normal speech while using the radio's microphone. Now disconnect the microphone and connect the controller. Adjust the transmit level on the controller for a similar range while speaking normally into the telephone microphone. A third possibility would be to use on-the-air reports.

Once you've gotten everything working, operation is very simple. Lift the telephone receiver and dial a two for the channel selected on the radio switches, a three, a four, or a five for the specific channels you've chosen. You'll need to set the volume for a comfortable level in the telephone receiver. By switching the power supply to the off position, reconnecting the microphone, and switching back to the internal speaker, the radio is restored to normal operation including the channel selector switches.

Improving God's IDer

Put more flexibility in the K2OAW circuit—and save the advantages of the original.

I have been a fan of Peter Stark's K2OAW IDer ever since the original design first graced these pages back in 1973. The simplicity of programming the thing, the low parts count requirement, and the lack of those hated Kernaugh maps made this, for me, the ideal IDer circuit. In the years since its first appearance, I have built maybe half a dozen of these circuits for my various repeaters and those of a few of my friends.[1]

With the advent of the FCC's decision to drop "R" calls for repeaters, regular

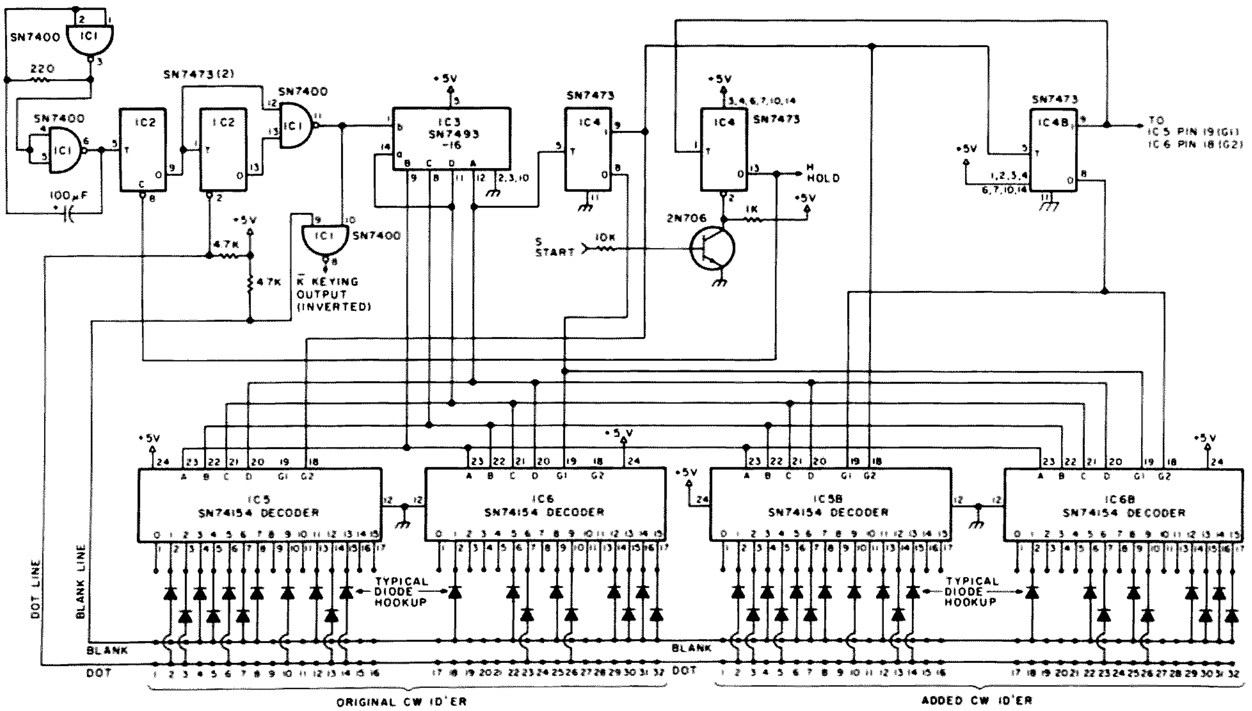

Fig. 1. K2OAW ID circuit update as it appeared in 73 in June, 1979.

amateur callsigns, followed by "RPT" or "/R", have generally necessitated more character space than the old K2OAW circuit could provide. So, a couple of years ago, Peter obliged the troops with an update of that original design which doubled, from 32 to 64 characters, the amount of information available for use in the IDer.[2]

However, though a lot of us need more than 32 characters for our ID, we don't always need *all* 64 of 'em, particularly those of us who believe that a repeater ID should say its legal piece and shut up. So, for those who wish to keep the ID process from continuing long after the CW is gone and to save a lot of diodes for the blank line, I hereby propose the "K2OAW IDer Update Update." As you will see, the improvements cover a lot more than what I've talked about so far.

Fig. 1 is the K2OAW ID circuit update as it appeared in the June, 1979, *73*. Peter added just 3 ICs, a 7473 (IC4B), and two 74154s (IC5B and IC6B) to accomplish the doubling of capacity. I changed the "ID hold" half of the original 7473 IC4B to a 74C76 (C? Yeah. Read on.), now called Z11A, and added one more IC, Z8, a 74C02 quad NOR gate. A 4001 would work just as well. To top things off, IC1A and IC1B, which comprised the clock oscillator in the original K2OAW circuit and its update, were scrubbed in favor of one half of an NE556 timer chip, running in the astable mode, with the other half being used for the ID audio oscillator. More on this later.

Fig. 2 shows how the two IC changes were implemented in the circuit. At the point in the ID where a stop bit is desired, two diodes are run to the appropriate pin on the 74C154 matrix, with one diode further connected to the dot line and the other attached to the blank line. The inputs of one gate of the 74C02 (Z8B) are connected to the dot and blank lines. This gate actually functions as a negative logic AND gate. When this aforementioned stop pin pulls both lines low together, the output of Z8B goes high.

This output is sent to two places, the "zero set" pins of Z3, which heretofore were grounded, and an inverter made from Z8A. Bringing the zero set pins on Z3 high sets all of its BCD outputs low. Grounding them allows the IC to operate normally.

The output of inverter Z8A feeds the "set" input on one half of the 74C76, Z11. A momentary low on this pin drives the $\overline{Q}$ output (also known as the ID hold line) low, halting the ID process in its tracks.

Z7A, half of the NE556, replaced IC1A and IC1B in the old circuit because the 556 is a much more reliable circuit, in my experience. The other half of the 556 is used in the astable mode as the ID tone generator.

IC1A and IC1B are not wasted, however. IC1B, now Z1B, is used to replace Q1, a 2N706 from the original ID circuit. It is connected as an inverter between the start line and the clear input of the 74C76. IC1A, now Z1A, is also used as an inverter, the input

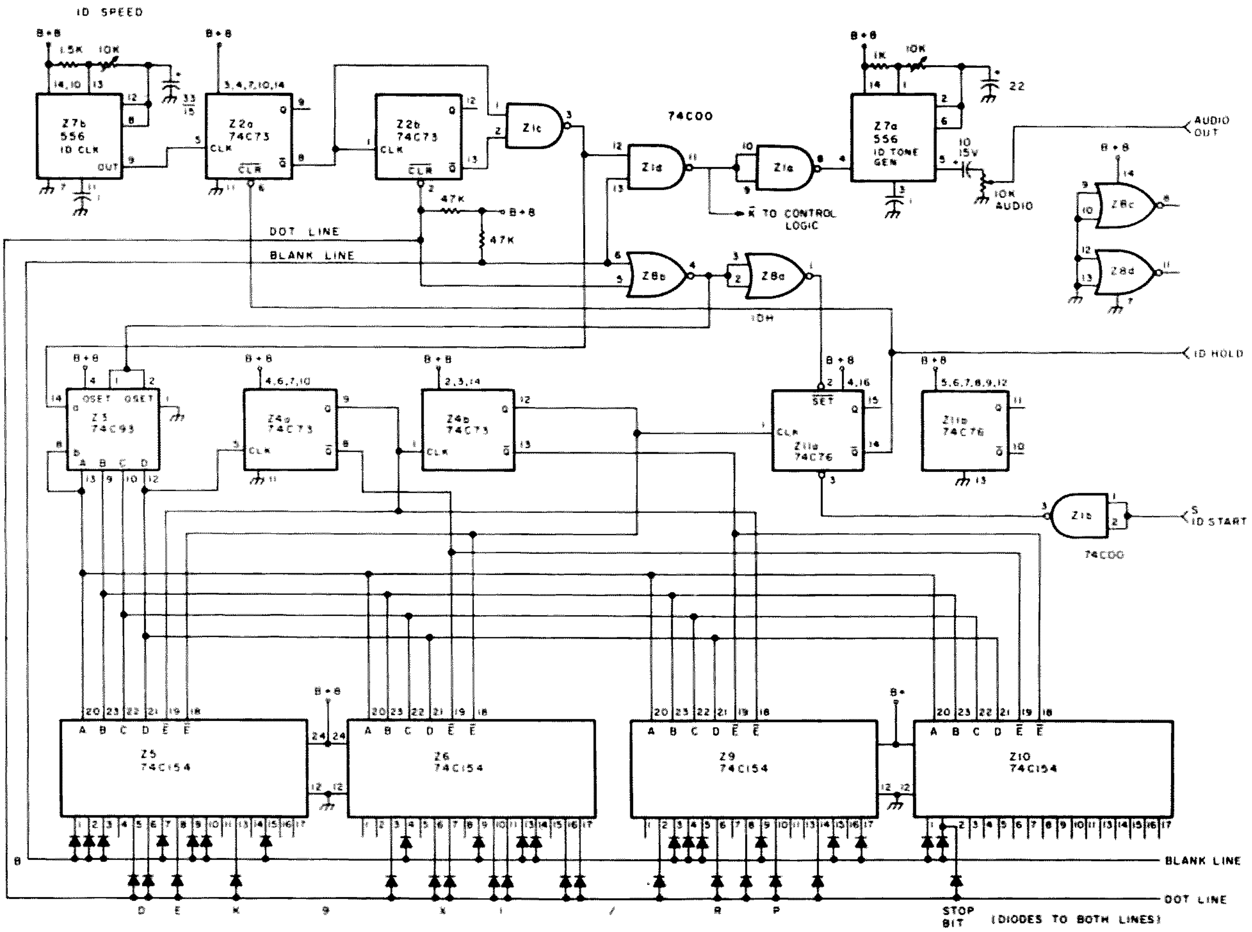

Fig. 2. The K2OAW update update.

connected to the $\overline{K}$ (keying) line, and the output connected to the reset pin of Z7B, keying the tone for the ID. The $\overline{K}$ line is still used for logic purposes.

The remaining two gates of Z8 are not used in this design and their inputs are grounded. Don't forget to tie all inputs of the other half of the 74C76 high. Leave the outputs floating.

Although this circuit adds 2 ICs to the design, it subtracts one transistor, and if your ID is short enough, you may be able to leave out Z10 as well, thus saving that expense. And you get a tone generator, a more reliable clock, and other improvements in the bargain.

About the 74C series: I switched all of my TTL to CMOS/TTL (by National Semiconductor) some time back. The savings in current is worth it, and the voltage requirement is not finicky like TTL. I use 8 volts on all my CMOS and timers.

One *caveat*: The 74C ICs used here are pin-for-pin replacements for their TTL counterparts *except* for the 74C93. If you're planning to retrofit an existing circuit and convert your 7493 to CMOS, you will have to rewire that part of the circuit.

With these modifications, I feel that the K2OAW IDer is the ultimate ID circuit. If you have one in use now and update to the circuit described here, I think you'll agree that the best has been made better. ■

TOUCH TONE DECODER KIT

HIGHLY STABLE DECODER KIT. COMES WITH 2 SIDED, PLATED THRU AND SOLDER FLOWED G-10 PC BOARD, 7-567's, 2-7402, AND ALL ELECTRONIC COMPONENTS. BOARD MEASURES 3-1/2 x 5-1/2 INCHES. HAS 12 LINES OUT. ONLY **$39.95**

NEW—16 LINE DELUXE DECODER **$69.95**

DELUXE 12-BUTTON TOUCHTONE ENCODER KIT UTILIZING THE NEW ICM 7206 CHIP PROVIDES BOTH **VISUAL** AND **AUDIO** INDICATIONS! COMES WITH ITS OWN TWO-TONE ANODIZED ALUMINUM CABINET MEASURES ONLY 2¾"x3¾" COMPLETE WITH TOUCH-TONE PAD, BOARD, CRYSTAL, CHIP AND ALL NECESSARY COMPONENTS TO FINISH THE KIT. **PRICED AT $29.95**

NEW—16 LINE DELUXE ENCODER **$39.95**

HAL ECD—16 LINE DELUXE ENCODER INCLUDES PC BOARD, ALL PARTS & CASE **$39.95**

HAL ECD—12 LINE DELUXE ENCODER COMPLETE WITH PC BOARD, ALL PARTS & CASE **$29.95**

ACCUKEYER (KIT) THIS ACCUKEYER IS A REVISED VERSION OF THE VERY POPULAR WB4VVF ACCUKEYER ORIGINALLY DESCRIBED BY JAMES GARRETT, IN QST MAGAZINE AND THE 1975 RADIO AMATEUR'S HANDBOOK **$16.95**

ACCUKEYER—MEMORY OPTION KIT PROVIDES A SIMPLE, LOW COST METHOD OF ADDING MEMORY CAPABILITY TO THE WB4VVF ACCUKEYER. WHILE DESIGNED FOR DIRECT ATTACHMENT TO THE ABOVE ACCUKEYER. IT CAN ALSO BE ATTACHED TO ANY STANDARD ACCUKEYER BOARD WITH LITTLE DIFFICULTY **$16.95**

BUY BOTH THE MEMORY AND THE KEYER AND **SAVE**
COMBINED PRICE ONLY **$32.00**

PRE-AMPLIFIER

HAL-PA-19 WIDE BAND PRE-AMPLIFIER, 2-200 MHz BANDWIDTH (−3dB POINTS). 19 dB GAIN
FULLY ASSEMBLED AND TESTED $8.95

HAL-PA-1.4 WIDE BAND PRE-AMPLIFIER, 10 MHz TO 1.4 GHz. 12dB GAIN
FULLY ASSEMBLED $12.95

NEW!

CLOCK KIT—HAL 79 FOUR-DIGIT SPECIAL—$7.95.

OPERATES ON 12-VOLT AC (NOT SUPPLIED) PROVISIONS FOR DC AND ALARM OPERATION.

6-DIGIT CLOCK • 12/24 HOUR

COMPLETE KIT CONSISTING OF 2 PC G-10 PRE-DRILLED PC BOARDS, 1 CLOCK CHIP, 6 FND COMM. CATH. READOUTS, 13 TRANS., 3 CAPS, 9 RESISTORS, 5 DIODES, 3 PUSHBUTTON SWITCHES AND INSTRUCTIONS. DON'T BE FOOLED BY PARTIAL KITS WHERE YOU HAVE TO BUY EVERYTHING EXTRA. WILL RUN OFF ANY 12-VOLT AC SUPPLY. **PRICED AT $12.95**

CLOCK CASE AVAILABLE AND WILL FIT ANY ONE OF THE ABOVE CLOCKS. REGULAR PRICE ... $6.50 **BUT ONY $4.50 WHEN BOUGHT WITH CLOCK.**

SIX-DIGIT ALARM CLOCK KIT FOR HOME, CAMPER, RV, OR FIELD-DAY USE. OPERATES ON 12-VOLT AC OR DC, AND HAS ITS OWN 60-Hz TIME BASE ON THE BOARD. COMPLETE WITH ALL ELECTRONIC COMPONENTS AND TWO-PIECE, PRE-DRILLED PC BOARDS. BOARD SIZE 4" x 3". COMPLETE WITH SPEAKER AND SWITCHES. IF OPERATED ON DC, THERE IS NOTHING MORE TO BUY*
PRICED AT $16.95

*TWELVE-VOLT AC LINE CORD FOR THOSE WHO WISH TO OPERATE THE CLOCK FROM 110-VOLT AC **WHEN PURCHASED WITH CLOCK KIT $2.95**

SHIPPING INFORMATION: ORDERS OVER $25 WILL BE SHIPPED POST-PAID EXCEPT ON ITEMS WHERE ADDITIONAL CHARGES ARE REQUESTED. ON ORDERS LESS THAN $25, PLEASE INCLUDE ADDITIONAL $2.00 FOR HANDLING AND MAILING CHARGES. SEND 20¢ STAMP FOR FREE FLYER.

The Bunesti Caper

The two British agents needed a power amp—fast. Could the American ham build one?

December 7, 1941, was a day of glory and achievement for the Japanese Empire because of the unbelievably effective attack upon military installations in Hawaii. In England, the long hoped-for involvement of America in the war now seemed assured. The "Day of Infamy," however, also brought a special sort of gloom and silence to one small segment of the American population—the amateur radio operators.

Photo A. The crew of Destiny Deb *prior to its final combat mission to Ploesti, Rumania. (The little guy on the left in the front row is W9PJF.)*

In the midwest that night, most of the ham bands were full of stations relaying the FCC announcement that all radio amateur activity was to cease immediately. It seemed that almost every ham in the country was trying to make as many contacts as possible that last night. I kept my 20-Watt AM rig (push-pull 45s modulated by 47s) going on 160 meters until well past midnight, but finally closed down when I got too sleepy to continue.

The next morning, I turned on my Howard 435A receiver and heard a couple of guys yakking away just as though the Pearl Harbor attack had never occurred. Naturally, I cranked up the rig and told them of the FCC notice. They claimed that my call was the first they had heard about it and that they thought their receivers

had been "desensitized by a storm." Of course, I didn't believe them for even a second, but that short chat on 8 December 1941 was to be my last ham QSO until World War II was over.

As a normal, healthy, high-school senior, I had no illusions about what the future held for me. I was caught up in the tide of rising national indignation at the treachery of the attack and looked forward to becoming a member of our armed forces. I hoped that my great interest and skimpy skills in radio might be useful. They were, of course, but there was a time still about 2-1/2 years away in my future when they were useful in a way I could never have imagined.

After graduation from high school, I found that the Army Air Corps was glad to have my services, but they insisted that I go to Miami Beach for basic training. This was to introduce me to the finer points of the military organization, to teach me discipline and respect for authority, to enable me to distinguish between my left foot and my right foot, and to educate me in a host of related subjects such as KP, policing the area, saluting, scrubbing the barracks, why all relationships with females are dangerous, etc.

During my third day at basic, an announcement was made that all personnel who knew Morse code were to report to the administrative office at 1300 hours. I reported as ordered and was given a short code test that was sent at about 10 wpm. I don't think that I missed a letter, and the next day I was on a troop train bound for the radio school at Sioux Falls, South Dakota. In my hands were records showing that I had completed basic training (?) and a promotion order making me a PFC! Those long hours practicing code in order to pass the ham exam had finally paid off, since I avoided many miserable hours of close-order drill.

The Air Corps radio operator/mechanic school had a curriculum that covered basic theory, Morse code, and radio repair. It included an almost frightening amount of material in a very short time, but I was having a ball. The films, lectures, and demonstrations expanded and solidified my knowledge of the theories I had struggled with as a ham. The code classes were pretty much of a bore and I did not advance my speed very rapidly, but I did manage to pass 35 wpm. We were not allowed to use typewriters, however, so I felt that printing at 35 wpm wasn't too bad.

The practical part of the course was a snap, and I became reasonably proficient at the operation and maintenance of such items as the BC-221 frequency meter, BC-375 transmitter, BC-342 and BC-348 receivers, ARC-5-series HF transmitters and receivers, BC-610 transmitter, SCR-522 VHF transceiver, and miscellaneous aircraft electronic gear such as beacon receivers, the radio compass, interphone systems, etc. I was happy to be expanding my knowledge of electronics and was actually a bit sorry when I completed the course.

I declined an invitation to stay at Sioux Falls as an instructor and requested an assignment as a flight radio operator. Within a couple of days I was on another train, now enroute to Kingman, Arizona, this time to qualify as an aerial gunner. I spent some time on the train sewing on my new corporal stripes.

Gunnery school did not have the same fascination for me that I had felt at radio school. While all of the radio operators at gunnery school had to participate in weekly code practice sessions in order to maintain proficiency, I learned a lot more than I thought possible (or necessary) about the 50- and 30-caliber air-cooled machine guns, the 20 mm cannon, hydraulically- and electrically-operated gun turrets, and how to lead or lag moving targets in flight. We spent a few hours in the air shooting at airborne targets, but I enjoyed the skeet shooting part of the course most of all. We learned the basics of leading or lagging moving targets by shooting at clay pigeons from the back of a moving truck! On days off, we were encouraged to shoot regular skeet—the guns and ammo courtesy of Uncle Sam. After the moving truck training, the normal skeet seemed easy and I was soon 25 for 25 most of the time.

I was not sorry to finish the gunnery course although it had qualified me for the first "flight pay" of my life. I left Kingman as a brand new "Buck" Sergeant, and headed for a combat crew assignment at Tucson, Arizona.

It would take a whole

Photo B. Back in Italy just before returning to the USA, W9PJF points to the souvenir Rumanian Air Force pilot wings worn by "Charlie" Kourvelas, the tail gunner.

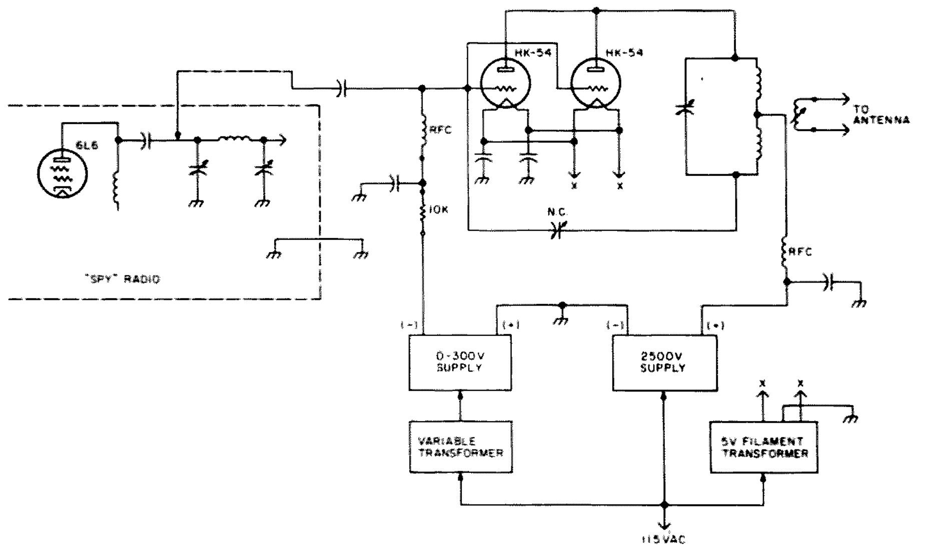

Fig. 1.

book to express my memories and feelings about our ten-man crew formed at Tucson. That crew became my family away from home, and a closeness developed between us that I have not experienced with any other group. Ten semi-trained civilians (four second lieutenants and six buck sergeants) became a reasonably competent crew for a B-24 Liberator, a heavy bomber. We soon were enroute overseas via Natal, Brazil, Dakar, West Africa, Marrakesh, and eventually to an austere base in southern Italy where our 450th Bomb Group joined the newly formed 15th Air Force.

I will always believe that aerial combat was at least as frightening as combat on the ground. Most of the time, our activities were conducted far inside enemy territory with the obvious risk of capture or death a long way from home base. We bombed a number of tough targets. We got shot at and were hit by fire from antiaircraft guns and fighter aircraft. We saw friends disappear in the cloud of an exploding aircraft, and we held back unmanly tears as corpsmen removed bodies from riddled airplanes. Our crew completed 34 missions with many close calls but with no physical wounds. Our flight engineer and I had been promoted to tech sergeant, and the other enlisted men now were staff sergeants. We were flying our third B-24, however: a nearly new one called *Destiny Deb*. Our first two aircraft had been totaled in crashes.

Our 35th mission was to bomb a target that was probably as well guarded as any in Europe. It was the oilfield/refinery complex at Ploesti, Rumania, which was a major source of petroleum products for the Nazi war effort. It was to be our second trip to Ploesti, and memories of the fighters and the intense antiaircraft fire were still fresh in our minds.

That mission turned out to be our last, as *Destiny Deb* was rocked by an enormous explosion just after we dropped our bomb load and while we were making a right descending turn to take up the return compass heading for Italy. An 88 mm shell had exploded between number two engine and the main fuselage, tearing a large hole in the fuselage and rupturing some fuel lines.

Only God knows why we were not immediately surrounded by flames. The number two engine quit immediately, and number three on the other side began to smoke. We fell well behind the squadron and obviously would soon be alone, an easy prey for any Luftwaffe fighters that saw our plight.

The Fates were again kind to us that day, however, and while the number one engine soon failed and power had to be reduced on number three, the old gal flew long enough for us to get well away from the target area. We realized that we would not see Italy very soon as reluctantly we parachuted out over open country near the small town of Bunesti, and soon we were uninvited and unwanted guests of the Rumanian government.

The life and times of a POW in that era cannot be described very well in a few sentences, but a great deal of my time was spent in planning what I might build as my postwar ham station. I was still constrained by my depression views, however, and my most grandiose design turned out to be a T-55 modulated by a pair of TZ-40s. For antennas, I considered the 8JK for 20 and 10 and perhaps a centerfed zepp for 80 and 40. Even the other radio operators in the Bucharest hospital POW camp considered my pages and pages of schematics to be a rather weird pastime.

The Allied invasion in June of 1944 gave quite a boost to our morale, and a spirit of cautious optimism began to spread. All that summer we treasured every scrap of information we could get about the Allied efforts in France. The Rumanians, however, were more concerned about their own future in view of the failures of the Nazi campaign in Russia.

The news of the war on the Eastern front reached us occasionally and, as the Russians advanced, our food improved measurably. The black bread was replaced by brown and the amount of meat in our thin stews seemed to be increased. The lieutenant in charge of our guards sometimes gave us copies of the local newspapers, and the rapid approach of the Russian troops to the Bucharest area was always a headline item. An aura of uncertainty and suspense appeared to envelope our captors and the element of fear could almost be felt. We heard rumors that British paratroopers had been captured, but it seemed hardly likely that any significant British airborne operation could be supported at this great distance from Italy.

One morning, an American major, accompanied by a Rumanian colonel and two men dressed in civilian clothes, entered our enlisted compound and asked if anyone had had any experience in building radio equipment. I explained my background in amateur radio and was told that two British agents had indeed parachuted into the area and that they needed a

power amplifier for use with their small suitcase-sized radio station. Their transmitter provided only about 20 Watts of power, and they had been unable to contact their station in Egypt.

I must admit that I was a little confused by a situation wherein an agent of a nation at war with Rumania was to be assisted by an American prisoner of war in establishing radio contact with an Allied radio station in Egypt. The Rumanian colonel told me that the rapidly approaching Russian forces had created serious political problems and that the British communications arrangements had been approved by "high government officials."

I said that I could build a suitable amplifier if I had the necessary parts, and one of the civilians replied that parts were available. After trading my flying suit for a pair of pants and a shirt, in order to appear less military, I gathered up my small collection of personal belongings and left the prison camp by car in the company of the civilians and two other radio operators, Charlie P. Brewer from Beaumont, Texas, and Ray Jones, RAF, from Sutton, Surrey, England.

We were taken to a large building which must have been part of a university physics department. I was escorted to a room that was full of electronic equipment and told to select whatever I needed. I found many American-made parts and some power supplies that appeared to be operational. I selected some triode transmitting tubes (they were either the HK-54 Gammatrons by Heintz and Kaufman or the 35TGs by Eimac—my memories have been somewhat dimmed by the passage of some 37 years), a 2500-volt power supply, a 300-volt power supply, tube sockets, variable capacitors, wire, solder, a variable transformer (Variac), and an assortment of rf chokes, resistors, insulators, and fixed capacitors.

There was no heavy solid wire available, and I could find no meters or test equipment. I explained my need for wire or tubing to make coils, and one of the civilians said that he would bring some later. The parts that I selected were placed on a bench, and the civilian said they would be delivered to the transmitter location that afternoon.

We left the building and were driven to the Banca Nationale A Romania (The National Bank of Rumania). In one of the basement rooms we were introduced to the two British agents. One was a British captain and the other a Rumanian national who also was a lieutenant in the British army. They showed me their small transmitter/receiver, and I was happy to see that they had several extra coil sets available which I could use in the amplifier circuit.

When the parts from the school were delivered, I assembled a simple power amplifier on a piece of pine board. Electrically, it was a pair of power triodes in parallel (see Fig. 1). The 2500-volt supply provided the plate voltage, and the 300-volt supply, Variac controlled, provided the bias. I used two of the spare coils from the "spy" radio for the amplifier-plate coil and checked for approximate tuning by coupling the output from the small transmitter to the antenna link on the plate coil. Resonance was easily established by tuning for maximum rf voltage in the tank coil.

Next, I capacity-coupled the grids of the power amplifier to the plate of the 6L6 output tube in the small transmitter. I hooked a flashlight bulb to the output link and carefully read-

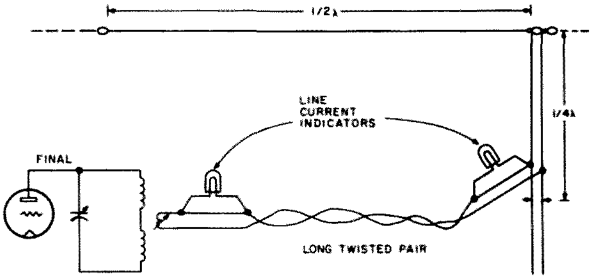

Fig. 2.

justed the amplifier plate, tuning for maximum output. Then the neutralizing capacitor was adjusted for minimum output, and the amplifier was ready for the first trial run. The flashlight bulb was replaced by a 300-Watt bulb, the bias voltage was set for maximum (−300 V) and the 2500-volt supply was turned on.

Surprisingly, nothing blew and no smoke appeared. By decreasing the bias voltage slowly and observing the intensity of the blue glow of the mercury-vapor rectifiers (866s) in the high-voltage supply, I could tell when the amplifier tubes began to draw plate current. I set the bias to a point where a definite plate current was evident and then keyed the small transmitter now being used as a driver for the amplifier. I was rewarded with a brilliantly glowing 300-Watt bulb and a large increase in the mercury-vapor glow.

The amplifier was indeed working and obviously was producing more radio energy than I had ever achieved with any of my ham gear. The only missing element now was an antenna, and the roof of the bank building was an awfully long way from the basement.

It was during this time period that a group of Rumanian leaders formed a provisional government, declared themselves the legal spokesmen, and agreed to cease combat activities against all Allied forces. I was introduced to Dr. Maniu who headed the provisional government and whose temporary abode was also in the basement of the bank. I understood that he had a long history of public service and was well thought of by the Rumanian people.

A man from the telephone company provided us with a large reel of twisted-pair telephone cable, a small reel of bare copper wire, and a great many glass insulators. Charlie, Ray, and I put a half-wave antenna with a quarter-wave matching stub on the roof and used the phone cable as a transmission line to the transmitter (see Fig. 2). The elevator shaft provided the shortest path for routing the cable between the roof and the basement.

During the installation of the antenna, the local German military authorities reacted immediately and harshly to the new government. Several Rumanian civilian facilities were bombed, and, for a few minutes one day while we were on the roof, we watched ME-109s dive-bomb nearby buildings. Luckily, the bank was not selected as a target.

I was concerned about the suitability of the phone cable as a radio-frequency transmission line because of the poor insulation and extreme length of the cable. (No one else there had ever heard about EO-1 cable). As it turned out, the phone cable was very lossy and the

UNIVERSAL M-600 MULTI-MODE AND CRYPTO-DECODER

— NEW —
DECODES:
TOR-SITOR

1280 AIDA DRIVE, REYNOLDSBURG, OHIO 43068

current flow into the antenna matching stub was much less than the current flow from the amplifier into the cable. In the final version of the antenna, the telephone cable was used as a single conductor connected to a water-pipe ground through the amplifier-output link. The cable length to the antenna was adjusted for best loading. This worked very well, and the British agents were soon in contact with the Allied radio station in Egypt. I have no idea of the purpose or content of their conversations as the messages were all encrypted—by use of the Bucharest telephone book.

The opportunity to improvise electronic equipment had been a splendid diversion, however, and during the two or three day period involved, I was directly concerned in an urgent project that was of value to our allies. During this period, I slept in the basement of the bank and food was sent in from a nearby restaurant. This was overwhelming in it's quantity, and I was never able to eat the entire portion. I took particular delight in the dill pickles since I had not tasted any since being shot down.

Within a few days, Russian troops entered Bucharest and the British and American POWs were flown to Italy in B-17 bombers with the protection of many P-51 fighter aircraft. We spent a few days visiting our respective squadrons and then departed from Naples for a fantastic voyage to the USA. By October of 1944, I was home on leave. I planned to ask for an assignment to a B-29 group so that I could get to the Pacific. That would also give me a chance to tinker with that new Collins rig, the ART-13. ■

REMOTE -O- MIKE

FM Wireless Mike

$34.95

- Range—up to 300 ft.
- FM Audio
- XTAL Controlled
- Simple Hook-up
- Reliable years of service

Stop: The steering wheel mike cord tangle. Stop: Running back and forth to answer a call on your radio. Stop: The inconvenience of being tied to your radio during long QSO's. The Remote-O-Mike may be connected to any HF, VHF or UHF ham transceiver. Just connect the Remote-O-Mike receiver to the mike input jack and each time you press the PTT button on your cordless mike your ham rig will function as your normal mike. The Remote-O-Mike receiver will provide both the PTT and audio to your ham rig.

Use in and around the house, auto, boat, etcetera. Just like a repeater with a range of up to 300 ft. Each Remote-O-Mike includes a XTAL controlled wireless FM mike and FM receiver. How do you spell mike cord tangle relief (Remote-O-Mike) Order today for your mike cord relief.

The Tube Returns

Move over, ICs. This receiver is easy to build, cheap, and works like a dream.

Bored with cranking out the contacts on your expensive transceiver? Been looking for a simple construction project to put some of the thrill back into ham radio? Maybe you'd just like to build something for the fun of seeing what you can make with that collection of old parts wasting away in the basement? If the answer is yes then this is for you.

Believe it or not, here is a surprisingly effective one-tube shortwave receiver you can build in a weekend. The cost is 0 to 15 dollars, depending on your resourcefulness. No slouch on performance, it will pull in just about every signal on the 80-meter ham band that an expensive commercial receiver will hear. As described here, it tunes from 3.5 to 7.5 MHz but the frequency range is determined by plug-in coils and can be extended easily in either direction.

Old-timers have already recognized this project as a regenerative receiver. This type of detector has its roots in the misty past of radio lore and its reputation for high sensitivity is well earned. Early amateurs found that putting an adjustable amount of positive feedback around a detector had several benefits: An astounding amount of gain was available, the selectivity of the associated tuned circuit was vastly increased, and with proper adjustment either AM or CW signals could be copied easily. If a dual triode is chosen for the tube, then one section can be the regenerative detector and the other an audio amplifier. The resulting receiver is easy to construct, sensitive, and inexpensive. It was a very popular design in the 1920s and 30s.

Photos by W1GSL

The one-tube wonder at work.

There are, of course, several drawbacks. To receive code signals the feedback is adjusted so the detector is just barely oscillating, and with that setting a long antenna blowing around in the wind can cause frequency instability on the higher bands. Since the detector is oscillating, a steady carrier can be broadcast via the antenna. A few microwatts isn't going very far but the ham next door might hear it. Furthermore, any receiver with a single tuned circuit will tune rather broadly. While that isn't too much of a problem when all of the signals in the band are of similar strength, a really strong station on a nearby frequency (within 30 kHz or so) can cause problems.

All of these problems were eventually solved with the development of the superheterodyne receiver, but the regenerative detector continued to be used, if to a lesser extent, because of its simplicity and sensitivity. Until the mid 1950s there was always a one-tube regen featured as a good beginner's receiver in the ARRL *Handbook*. Even in the 60s there were designs for simple superhet receivers using regenerative detectors and controlled amounts of i-f regeneration to sharpen selectivity.

So much for history; let's turn to the project at hand. This circuit is a distillation from several described in the literature of the 50s. I tried not to use components that would be difficult to locate today and I'll point out a lot of circuit alternatives to take care of the most likely junk-box shortages.

The receiver uses a plug-in coil—wound on the glass bulb of an extra octal tube—and covers 3.5 to 7.5 MHz. With that coil, the 80-meter band is covered with plenty of bandspread and the 40-meter band tunes pretty rapidly. You can wind other coils easily to cover 40 and 20 meters with plenty of bandspread.

The 80-meter tuning range is a good place to start since that band is not too crowded and the shortcomings of this simple receiver will be more pronounced on the higher frequency bands. The construction is genuine breadboard: very simple and easily adapted

2

to whatever parts you collect. The performance is remarkable. With a 30- to 50-foot endfed wire you will be able to copy just about everything on 80 meters, SSB included, without much problem. In fact, the 80-meter performance compares quite favorably with that of a 5- or 6-tube "all-wave" receiver. The regenerative detector won't tune as conveniently as the superhet, but with a little practice the results are the same.

The Circuit

The circuit diagram for my receiver is shown in Fig. 1. You can copy it exactly or use it as the starting point for your own version. Before getting into possible variations let's take a close look at Fig. 1.

The antenna is link-coupled to the detector coil through three or four turns of wire. This is the swinging coil visible in the photograph. There are two tuning knobs. One 365-pF section of the tuning capacitor from an old tube-type broadcast radio does the main tuning while a smaller, 140-pF variable, tapped down on the coil, is the slower tuning bandspread capacitor. A three- to four-turn feedback winding on the bottom end of the plug-in coil allows the detector to oscillate when the regeneration control is set high enough.

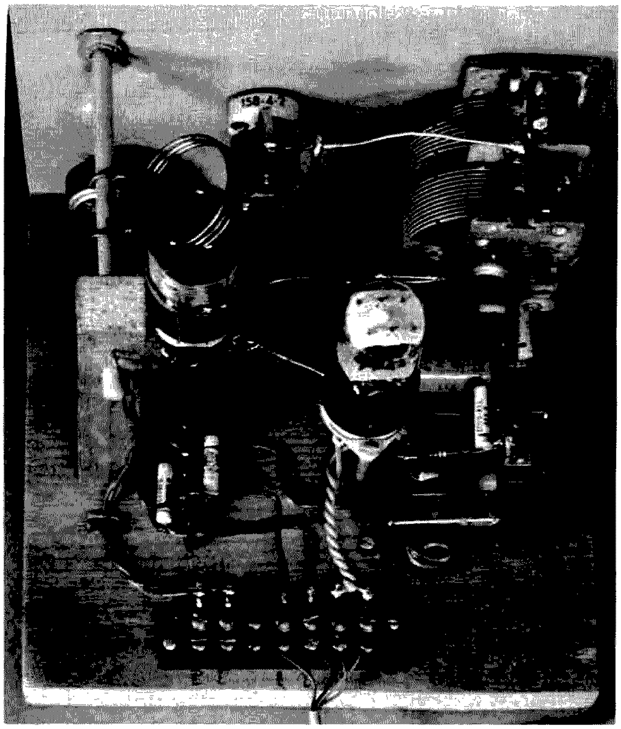
The plate lead from the detector triode is filtered clean of rf after running through that feedback winding and the audio is capacitively coupled into the grid of the audio-amplifier triode. An inductor (the primary of an audio-output transformer) keeps the audio from getting back to the power supply and a 25k pot sets the regeneration level by adjusting the detector's plate voltage.

The audio amplifier is pretty straightforward, except perhaps that the headphones are connected directly into the plate lead. This is simple and works well but please note that the B+ runs through the headphones and you should be mindful of the shock hazard. The headphone jack is wired so that the voltage doesn't appear on the external part of the jack (which is normally grounded) until the 'phones are plugged in and, of course, the jack is insulated completely from the front panel.

The power supply is correspondingly simple. Two small filament transformers feed each other back to back to provide both the 6.3 volts for the filament and a transformer-isolated 115 volts for the B+ supply.

Construction

The physical design is straight out of the 50s. A 7½- by 8-inch board is the base for the receiver, and most of the parts are mounted on terminal strips screwed to this board. The two tube sockets are mounted on 1-inch standoffs. The front panel is a piece of 1/16-inch aluminum to which are mounted the various controls. Most of the rf wiring is hung on the tuning capacitors, so it is important that the front panel be mechanically rigid and electrically shielding. These two conditions ensure a minimum of problems due to microphonics (audio noise in the headphones due to mechanical disturbance of the electrical parts) or hand effect (frequency shifts caused by circuit capacitance variations due to motion of the operator's hands near the receiver).



Behind the dials: A simple circuit and classic breadboard construction.

The antenna is coupled into the tuned circuit by means of a swinging link coil. As can be seen in the photograph, this link is mounted near the middle of a 5-inch length of 1/4-inch-

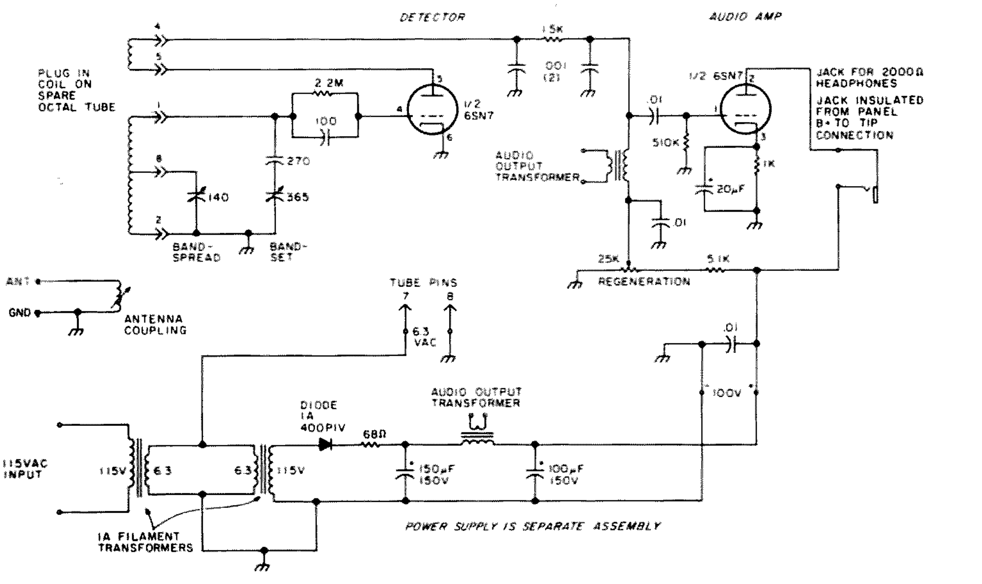


Fig. 1. One-tube receiver schematic.

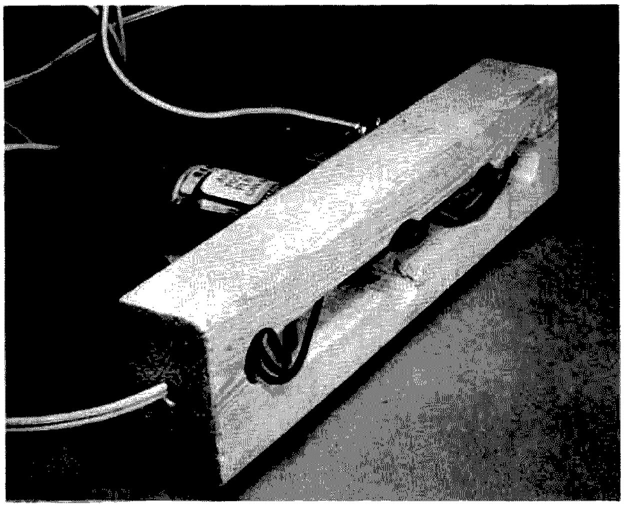
(3)

diameter plastic rod. The rod need not be plastic—any insulating material will do, even wood. The rod is supported at the front panel by a bushing (which was salvaged from an old volume control in keeping with the spirit of the project) and at the other end by a wooden pillar having a 1/4-inch hole through it in the appropriate spot.

The link was formed by winding stiff wire around a wooden dowel slightly larger in diameter than the 6SN7 coil form. The wire is kept under as much tension as possible while winding. The time-honored method is to clamp one end of the length of wire in a vise and, with the wooden form held in both hands, lean back to put tension on the wire as you wind your way toward the vise.

The coil will spring out some when it is taken off the form and probably several turns at the start will be distorted. Save three or four good turns with an inch and a half or so of lead on them. When the rod and 6SN7 coil form are both mounted, you can measure where the antenna link will have to go on the shaft in order to swing over the coil. Drill a pair of wire-diameter-sized holes at the appropriate spots and mount the link through them.

The rest of the receiver layout is pretty well defined in the photographs. I used heavy wire for all of the rf wiring so that vibration-induced microphonic effects would be at a minimum. Your layout doesn't have to match mine exactly as you surely won't have a matching collection of parts.



The power supply: built on a hollowed-out length of 2 × 3.

The construction style of the power supply is also historically motivated. The supply is built as a separate unit to minimize 60-cycle pickup in the receiver. I used a 1-foot-long section of wooden 2 by 3 with a slot jigsawed down the middle to contain the wiring. One concession was made to modern electronic design in the form of a silicon rectifier mounted on a terminal strip hidden under the "chassis." In earlier years, there would have been a 5Y3 or type-80 rectifier tube in the supply.

Alternate Parts and Circuits

Half the fun of building the one-tube receiver is coming up with a suitable collection of parts. The circuits are so noncritical that the builder can substitute with wild abandon and still have excellent results. This is especially true of the power-supply circuit.

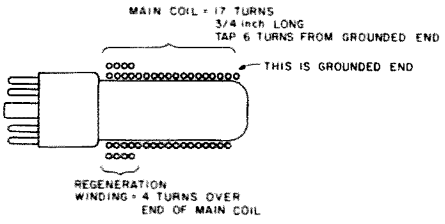


Fig. 2. Coil data for 3.5-7.5-MHz coil.

The receiver needs 6.3 volts ac at .6 Amps and 90 to 200 volts dc at 8 to 20 mA. If you're lucky, you will have a single small transformer providing these voltages and probably 5 volts as well (for a rectifier filament) that you won't need. I didn't have any suitable small power transformers, but I did have a collection of filament transformers. Two were wired back to back as indicated in Fig. 1.

Of course, it is all right to use a single large transformer if that's what's available. If the voltage is too high (250 volts or more), a 10 or 15k, 1-Watt resistor can always be used in place of the filter inductor. A really large transformer, like that from an old TV set, should probably be mounted on a metal chassis for safety's sake—an inverted cake pan will serve if the junk box lacks a chassis.

The rectifier I used is a small silicon unit rated at 1 Amp and 400 peak inverse volts. A full-wave bridge rectifier would be nicer since the 120-cycle ripple is easier to filter than the output of a single diode. The more filter capacitance the better. Don't be afraid to experiment with smaller amounts than I used, but be prepared to add more if hum is a problem. Be sure the capacitors are rated to work at voltages higher than they will see in the circuit. The filter inductor would ideally be a small 5- to 20-Henry unit rated at 20 mA or more. Small chokes, like small power transformers, are not too plentiful these days, so I used the primary of a salvaged TV set audio-output transformer instead.

An entire alternate receiver schematic is shown in Fig. 3. I haven't built a receiver using this schematic, but it is included here to illustrate a number of circuit variations. You can mix and match circuit features from Figs. 1 and 3 to make maximum use of the parts you have on hand. Note first how the antenna is capacitively coupled to the tuned circuit. If you have a small variable capacitor and a big knob, you may find this version easier to build than the swinging link. Both sides of the capacitor must be insulated from the panel and the large knob is desirable since placing your hand near the control shaft may influence the antenna coupling. This circuit arrangement was used in the 1952 ARRL *Handbook* receiver with a homemade capacitor constructed much along the lines of my swinging link—though plates were used instead of coils, of course.

If you have another small capacitor with a suitable shaft, you can use it as a bandspread capacitor. The smallest variable I had was 140 pF, so when I wound my coil I put a tap a few turns up from the ground end and connected that larger capacitor across only part of the coil. A 10- or 15-pF variable can go across the entire coil as shown in Fig. 3, and if you only have several 365-pF units, you can use a tap on the coil even closer to ground than mine. Don't overlook old FM radios as a

source of small-value variable tuning capacitors. UHF TV tuners are another possibility and they often have a built-in vernier dial as well.

The 100-pF coupling capacitor can be any value from 50 to 250 pF and the grid-leak resistor can range from 1 to 10 megohms. Even the tube itself can be changed; a 12AU7 or 6CG7 will work as well as the 6SN7, though the base wiring and filament needs will be different. Naturally a real plug-in coil form will work as well as the spare 6SN7 I used, and any straight-sided glass octal tube will do the job as well as a 6SN7. Be careful not to use both filament pins of a tube for coil connections unless the filament is burnt out. I used #24 solid insulated wire for winding the coils. The coil ends are brought down over the outside of the tube base and soldered to the ends of the pins. A dab of cement holds the wires in place on the glass.

One big change in the circuit of Fig. 2 is that the regeneration control has been replaced by a 365-pF variable capacitor. There is a good reason for this circuit change: lower adjustment noise. The trouble with the 25k pot used in Fig. 1 is that it has dc flowing through it. Carbon pots, unlike wire-wound ones, develop contact noise when used this way and eventually sound scratchy when rotated. I used the carbon pot because wire-wound ones are hard to find, but the variable-capacitor approach is a better solution to the problem and you may want to try it.

A 1- or 2.5-mH rf choke is used in the plate circuit and an audio-interstage transformer provides coupling to the audio amplifier. The audio-output transformer used for this purpose in Fig. 1 could also be replaced with any power-supply-type choke rated at more than 10 mA and 2 H or so inductance. Also shown in Fig. 2 is an audio transformer or supply choke used as a dc feed path for the audio amplifier. This permits ac coupling to the headphones and gets them out of the dc side of the circuit. If your main interest is in CW work, you may want to add some audio selectivity by placing a capacitor across the transformer winding as shown. The resulting tuned circuit can be set to the desired audio frequency by adjusting the capacitor value on a cut-and-try basis. The actual value will depend on the inductance of the transformer you have. Try starting with .01 or .05 uF and listen for an audio peak as you tune across a CW signal. Use a larger- or smaller-value capacitor to lower or raise the peak frequency as necessary.

Operation

Getting the most out of this little receiver is going to require some practice because the controls interact more than they do on a modern superhet. Peaking the preselector control on a transceiver may change the speaker volume a little, but you don't expect it to alter the i-f bandwidth or receiver tuning! Basic operation of the receiver is as follows: The main tuning is set to the approximate frequency of interest and the bandspread control to the middle of its range. The antenna-coupling link is positioned over the top of the coil and the regeneration control advanced. A "plop-hiss" noise in the headphones announces that the detector has started to oscillate. The control is positioned just after the oscillation starts and the receiver is tuned to a signal with the two tuning capacitors.

You will find that the sensitivity and selectivity are greatest with the regeneration set so the detector is close to the oscillation threshold. CW and SSB signals are copied with the detector oscillating, while for AM reception the regeneration is backed down just below the threshold. Often it is easiest to find a signal with the regeneration turned a bit to one side of the critical setting. Increasing the antenna coupling brings up the headphones volume but also reduces the amount of regeneration present and changes the received frequency slightly. The regeneration setting needed to maintain oscillation will vary some with frequency as well. All of this sounds more difficult than it really is. After a little experimentation, you'll find yourself pulling in an amazing number of signals.

Troubleshooting and Calibration

One side benefit of this design is that there is so little to go wrong. If the receiver is built according to the schematic and with good parts, it will most likely work when turned on. If it doesn't, and a series of circuit and voltage checks indicates that everything is OK, then the problem is probably with the regeneration coil. Try reversing the connection of the link winding. If the receiver cannot be made to oscillate on the lower end of the tuning range, then slide the feedback winding closer to the main coil. The coil dimensions recommended in Fig. 2 will surely get you off to a good start but you may wish to experiment with different geometries.

Once the receiver is pulling in signals, you will want to calibrate the dials. This is easy to do with the help of another receiver since the oscillating regenerative detector generates a weak carrier on the frequency to which it is tuned. Set the calibrated receiver to a given frequency, turn up the regeneration control on the little set, then sweep its bandset knob until you hear its carrier in the other receiver. At that setting the two receivers are listening to the same frequency. I glued a paper scale behind my tuning knobs and marked the bandset-dial

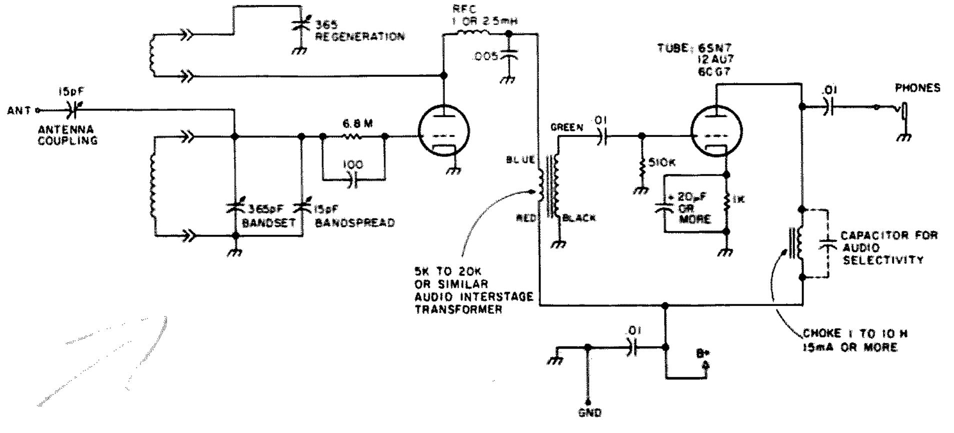

Fig. 3. Alternate schematic showing some possible circuit variations.

position at every half megahertz. The bandspread dial was marked for the 80-meter Novice band and the whole 40-meter band. Of course, the bandspread calibration is only accurate when the bandset knob is set properly.

Other Coils

Changing the tuning range means winding other plug-in coils. Simply use more turns to go down in frequency and fewer to go up. On the higher bands, space out the turns so the whole coil is 1/2 to 3/4 of an inch long. The number of regeneration turns should also increase or decrease one or two, in step with the main coil change. If your main tuning capacitor has two sections, you can place jumpers across otherwise unused coil pins and wire the socket to use both capacitor sections on low bands and only one on the higher frequencies.

A Word of Warning

This little receiver is really a lot of fun to operate. It is cheap to build and can be thrown together in a weekend. If there are a few spare octal tubes on hand, the frequency range can easily be extended in either direction. One word of caution is necessary though. The time will come when you tune across 80 meters with this set and realize that you *can* hear just about every signal on the band. In fact, you could actually use this little gem to make some real contacts (and enjoy shaking up the ham on the other end with a description of your receiver)! After you do that several times you'll naturally start to think about one-tube QRP transmitters. So when nosing around the local flea market for 6SN7s keep an eye out for a slightly larger power transformer, a 6AG7, some 80-meter crystals, and maybe a few old B&W plug-in coils. ■

The Program That Knows It All

Repeater info, third-party agreements, you name it—this TRS-80 BASIC program knows it.

"Hey, OM. Shall I QRQ?"

"Er, uh, yeh. I guess." Boy, I sure wish I knew what he meant! Where did I put that list of Q-signals?

I operate contests quite a bit. I keep a dupe sheet in front of me, but I sure wish I could search through those calls faster!

Has it been ten minutes since I last IDed? Six minutes? Or 12?

Just showed that FCC examiner a few things and upgraded my license. Now let's explore this new territory . . . umm, how far down can I go? Am I in the phone portion of this new band?

Familiar situations? Well, now you can relax. This versatile program will put fun and pleasure back into your hamming. Just by inputting a bit of information about a repeater station (last three letters of its call, its frequency pair, or its location), the program will provide all the information concerning that repeater. If you are a contest operator, this program was made for you. It provides dupe sheet capability with memory and fast recall. No more lost contacts while you check your log to see if you worked that station. Those infrequently used Q-signals are now available when you need them and there is no more wondering whether that country has a third-party agreement before running the phone patch.

MENU OF COMMANDS
1. REPEATER INFO
2. CONTEST OPERATOR
3. Q-SIGNALS
4. THIRD-PARTY AGREEMENTS
5. IDER
6. FREQUENCY CHECK
7. EXIT
COMMAND?

Fig. 1. Sample run of commands available for user.

Fig. 2. Frequency check display showing 3.5-MHz band with operating frequency of 3.7 MHz. A display is provided for each band, 80-2 meters.

I remember when I upgraded and was operating on new and unfamiliar bands, I was constantly referring to a chart to see where the band limits were and if I was still in the phone or CW portion of the band. Before using this program, I still had to resort to that chart when I would occasionally operate on a seldom used band. Now the computer will verify the legality of my operating frequency and visually display where I am operating within that band.

Last but not least, the program provides a visual reminder to satisfy the station identification requirement and will give a flashing reminder when it is time to identify.

Written for the Radio Shack Level II TRS-80 with 16K memory, the program requires about 9K to run. Since there are no unique statements, it should readily adapt to other BASICs. The overall program is actually composed of seven different subprograms. By compartmentalizing it in this manner, the user may choose all or portions of the program to fit his particular needs or memory capability.

Program action is simple to follow. Just respond to the computer's requests and you cannot go astray. The program should be loaded and ready to use when the operator sits down for a hamming session. Then he will have all these capabilities at his fingertips.

Program Introduction: Statement lines 1 through 52 graphically introduce the program and ask the user to input his choice of subprograms. I have made extensive use of the INKEY$ function throughout the program. This allows faster responses and saves wasted effort by not having to use the ENTER key to input data. Safeguards have been incorporated to prevent the program from crashing if a wrong key is inadvertently hit.

Favorite Repeater: Statement lines 100 through 288 comprise the repeater infor-

Program listing.

mation program. When the user responds with the last three letters of the repeater's callsign, its frequency pair (e.g., 13/73), or the city where it is located, the computer will display pertinent information concerning that repeater. One helpful bit of data provided is the proper beam heading for that repeater. Lines 120 through 197 and 200 to 279 are reserved for the user to insert information pertaining to his favorite repeaters. I have put data in these lines just to provide formatting examples.

Contest Logger: This routine is the answer to the contester's prayers. It resides from lines 300 to 338. It will ask for the callsign of the station, check memory, and, if not already logged, will tell the operator that it is a new contact and to call it. If contact is made, the call can be saved in memory for recall later. If the station was previously logged, the user will be informed so that a different station can be checked. Searching action is completed in seconds—a lot easier than trying to find a callsign in a stack of dupe sheets! Statement line 11 is initialized for 100 contacts. This can be adjusted if desired.

Q-Signals: How many times have you heard a Q-signal used and tried to remember its meaning? Statement lines 500 through 603 provide instant recall. The user enters his own catalog of Q-signals into DATA statements beginning on line 600. I have already inserted 23 signals. These can be altered to suit individual needs. The only program modification required is changing the DATA statements and lines 525 through 547 to support the changes made. Be sure the last DATA element is "END".

Third-Party Agreements: This program will display the list of countries with which the United States has third-party agreements. Statement lines 700 to 732 support this function. The list includes call letter prefixes. If the country is not listed, do not make that phone patch!

Station Identification: The operator can initiate this program when the QSO

(where's that Q-signal program!) begins. A visual timer will be displayed, updated each minute, and provide a flashing reminder when the time limit has expired and station identification must be made. When the ID has been made, the time can be reset and the sequence repeated. Reset can occur any time by hitting the "R" key. Hitting "S" returns the program to the menu of commands. This IDer routine is in statement lines 900 to 954. The timing sequence is software controlled (FOR...NEXT loop) and may have to be adjusted to allow for differences in machines. Line 914 controls this timing.

Frequency Check: The largest and most complex subprogram, it resides from lines 1100 to 2007. Don't let that scare you, though. If you answer all prompts and data requests when required, the computer will provide the proper response. The program is designed to give the operator the security of knowing his operation is within the band limits established for his license. This verification is supported as the program is run and then reinforced by graphically displaying the operating frequency.

The frequency program can be customized for specific requirements. For example, if you always intend to remain a General, eliminate lines 1102 through 1121 and change lines 1100 and 1122 to read:

1100 CLS
1122 LET C=71

This eliminates answering the class of license question each time the program is run. If your operation is confined to one band, make variable B at line 1146 the applicable value. Also, if you never use CW, make M=80 at line 1160 to establish phone-only operation (also delete lines 1156 and 1157).

As previously stated, this is a highly versatile and useful program, either piecemeal or in its entirety. I believe it contains some routines which every ham will find helpful. I hope it will take some of the paperwork out of your operation and give you more time to rag-chew! ■

Berserk Direction-Finding

Zero in on transmitters in seconds with this TRS-80 program. It will tell you how to get there, too.

In any radio direction finding operation, whether it be tracking a jammer or a distress signal, the time factor is important. The Radio Amateur RDF Assistant minimizes the time involved in tracking a transmitter. The program allows the operator to determine the general location of the transmitter instantly by entering the headings to the transmitter from two stations whose locations are known. The advantages of this method over the standard map, protractor, and straightedge approach are speed and accuracy. The high speed of the operation allows for comparison of headings from different stations and for quick, repeated calculations if the transmitter is moving.

Other features of the program include the giving of directions to the transmitter for field units and providing a listing of the DF committee members and repeater users, with their calls, phone numbers, and distances and directions to the transmitter, allowing the RDF net control to coordinate the efforts of the stations in reaching the transmitter site. The data for this listing is stored on tape, so the user may have different tapes for different repeaters or bands.

Instructions

After you have CLOADed the program and entered RUN, the computer will ask you if you want the data tape loaded before continuing with the program. You would normally do this when stations will not be giving you bearings immediately, such as right after a jammer or ELT has appeared on frequency. If you need to determine the transmitter's location immediately and have the appropriate information, enter N and the program will continue. You may load the tape later if needed by selecting that option from the menu.

Next, the computer will ask you for the coordinates of station A. Type in the horizontal coordinate, a comma, and the vertical coordinate of the first station that you will be taking a bearing from. (This information can be found by preparing an RDF Map and a Station Data Sheet described later.) Press ENTER and the computer will then ask you the bearing that that station has on the transmitter. Type in this and press ENTER. Repeat the procedure for station B, using a second station. It should be noted that you should not enter two stations that have the same bearings or whose bearings have a difference of 180°. This will result in a divide-by-zero error. This situation is rare and even if the computer were not used the results would be meaningless. The user should simply select another station to replace one of these.

Once this has been done, the transmitter's location is printed along with directions and distances from stations A and B to the transmitter. To see the list of options available, press ENTER.

The first option is DF-Fix Calculations, which was just described. You would select this option if you want to enter a new set of headings to the transmitter. This is the only option that affects the transmitter's location. The other options only use this data to provide related information.

The second option provides directions to the transmitter for a field unit. The computer will ask you for the coordinates of the

field unit. Enter these coordinates. The coordinates can be found by finding the field unit on the RDF Map and finding its corresponding coordinates. The computer will then display the transmitter's location and the distance and directions to the transmitter from the field unit. This information is presented in two forms to allow for different types of field units. If the field unit is a car restricted to streets, the north/south and east/west directions are more appropriate. On the other hand, if the field unit is on foot or in open country, distance and bearing information is more relevant.

The third option is the DF-Net Listing. To use this option, you must have loaded the data tape in or inserted new data (option 5.2) during the current run of the program. The computer will first ask you for a maximum report range. The computer will list only those stations which are within the number of miles you entered to the transmitter. The computer will then ask if you want only DF committee members (those with asterisks at the front of their calls) to be listed. Enter either Y or N. The computer will then list the stations on the screen. It will only show eleven stations at one time, so merely press ENTER to see the next set of eleven. After the computer has listed all of the stations that have met the given requirements, it will tell how many stations were within the given range. You must press ENTER to see the list of options.

The fourth option is to load the data tape. The computer will guide you through the process of loading the tape. The menu will be displayed after the tape has been loaded.

The fifth option allows you to modify the data tape of the DF-Net stations (callsign, phone number, and location). How to determine the station's location will be discussed later. This option has five options of its own. The first merely lists the data. This allows you to check the data and see what, if anything, needs to be changed. The number displayed on the extreme left is a record number. This is the record number you will use in options 2 and 3. Before using options 2 and 3, it is a good idea to check the listing to make sure that you select the right number. To insert a new record, first determine after which record you would like the new record inserted. If it is the first record to be inserted, insert it after Ø.

The third option is the delete option. If you have a station which is no longer active or needs to be deleted for some other reason, find it on the listing (option 1) and note its record number. Then select option 3. Enter this number in response to the computer's question about which record number should be deleted. If you choose to de-

Program listing.

lete a record number that does not exist, the computer will print RECORD NOT FOUND and ask you for the record number to be deleted again. If a record has some incorrect information on it, you must insert the complete correct record and then delete the incorrect one.

The fourth option will write a new data tape with all of the new changes or duplicate the old data tape if it has been loaded in and no changes have been made. To use this option, place the tape you want to put the data on in the recorder. Press the Play and Record buttons on the recorder and then press ENTER on the computer. After the data tape has been written, the computer will return to the main program and display the menu.

The fifth option simply returns you to the main program and displays the menu. You would select this in case you did not want to write a new tape or did not want to write immediately after making the changes.

RDF Map

In order to use this program, you must prepare a map with a coordinate system on it. First obtain a map of the coverage area. This map should have an appropriate scale for RDF use, that is, it should not be so small that one inch equals twenty miles. After the map has been obtained, you should determine what length on the map corresponds to a distance of one mile; for example, 0.5 inch=1 mile. Then, starting in the left-hand corner, you should make a mark every mile along the bottom edge of the map (see Fig. 1). Do the same along the top edge, starting in the upper left-hand corner. Repeat this procedure for the sides, starting in the lower left- and right-hand corners. Next, label them, starting with Ø and going from left to right and bottom to top. The markings on the side of your map should be similar to those in Fig. 1 (different scales and more numbers of course).

After you have prepared the map, you are ready to prepare the DF-Net station data sheet (see Fig. 2). Fill in the call and phone number columns with appropriate information. The first coordinate is the number on the top or bottom of the map which corresponds to the horizontal position of the station. The second coordinate is the number on the sides of the map which corresponds to the vertical position of the station. This sheet is sufficient for using options 1 and 2 of the program.

As has been stated before, in order to use the DF-Net Listing option, you must have previously inserted stations onto the data tape using option 5.2. The option will guide you through the procedure, but a few things should be mentioned before you use the option. First, answer all of the questions the computer asks about the station. Do not leave any answer blank. If a radio direction finding station does not have a call, (e.g., a future ham or SWL), type his name (if it is six or less letters) or his initials in response to the question about the station's callsign. If a station does not have a phone or his number is not known, type in NO PHONE or N/A in response to that question. If you would like a station to be included in a selective printout in the DF-Net Listing, put an asterisk in front of the station's callsign. The asterisk can be used to denote a station who is part of the DF committee or to denote those who have special RDF equipment in their cars, etc.

As well as using the program to find stations, it can be used to calibrate the members' antenna-heading indicators. To use the program for this purpose, RUN the program and load the data tape. Next, you need to insert the coordinates of the station that everyone will be aiming at. To do this, enter station A's coordinates as follows: first coordinate of station being aimed at, Ø. For the bearing, enter Ø. Enter B's coordinates as follows: Ø, the second coordinate of the station being aimed at. For the bearing, enter 90. Press ENTER to get to the menu, and select the DF-Net Listing option. Answer the questions as you normally would. The number in the bearing column of the listing is the direction that each station's heading indicator should show. This information should be relayed to each station so that he can either correct his indicator or make a note of the error and correct for it when he is tracking a station. A good station to calibrate on would be the repeater.

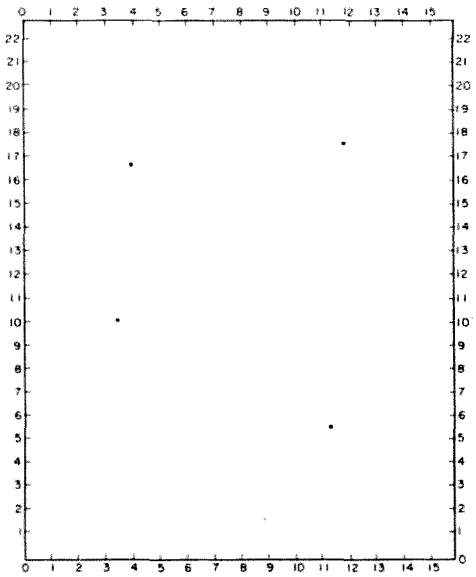

Fig. 1. RDF map.

CALL	PHONE NUMBER	COORDINATES	

Fig. 2. DF-Net station data sheet.

You also may want to include the repeater in your DF-Net Listing so you can estimate the station's transmitter power by comparing the distance to the repeater with the signal strength into the repeater.

Technical Data

The program is divided into six subprograms (DF-fix calculations, field-unit calculations, DF-Net Listing, loading the data tape, modifying the data tape, and the menu) and one major subroutine.

Statements 5 through 12 merely initialize the program. String space (5000 bytes) is set aside and the arrays are DIMensioned to a value of 100. Statements 15 through 21 give the user the option to load the data tape before he actually starts to use the program.

The DF-fix routine (lines 39 through 113) determines the location of the transmitter from the information entered by the user. This location (G,H) is used in all of the other routines for determining the transmitter's relationship to the positions of the other stations.

Statements 40 through 60 prompt the user to input the tracking station locations and beam headings. Statement 75 converts these headings from compass bearings (0° = North, increasing in a clockwise direction) to polar bearings used by the computer. Statement 90 converts these headings from degrees to radians and takes the tangent. Statement 100 solves the simultaneous equations representing the lines from the tracking stations at the given bearings. Statement 105 rounds the results of the calculations (G,H—the transmitter's coordinates) to the nearest tenth. Statement 110 passes station A's coordinates to the variables used in the calculations subroutine. The results are then printed out.

Subroutine 1900 is called to print the directions, since it is used many times. This is again done for station B in line 113. The last half of line 113 is a dummy input used to pause the program and allow the user to continue when he is ready. This is done frequently throughout the program.

The field-unit routine prompts the user to input the field-unit's coordinates, calls the calculations subroutine, and displays the results. It then jumps to the menu. This routine is straightforward in that all it does is format the input and output of the calculations subroutine.

The DF-Net Listing first checks the data flag (DF) to see if data has been loaded in (line 181). The computer then prompts the user to input different parameters for the listing (lines 185 and 190). RN is the record number and specifies which element of the array is to be read. The computer compares the record number with the total number of records (TR). When RN exceeds TR, the listing routine then summarizes the results of the listing. If the user selects the selective printout, the program then checks to see if the first character of the callsign string (D$) is an asterisk (line 215). R is the "stations within range" counter and V is a line counter for limiting the number of stations printed on the screen at one time so that the results do not go flying off the screen before they can be read.

The data tape input routine is also straightforward. DF=1 sets the data flag. One record, D$,E$,X,Y, is input off the tape and stored in an array, with the subscript being incremented after each record. The computer checks D$ for the end of file indicator, END. TR is found by taking the total number of records read (RN) and decreasing it by one to remove the end-of-file indicator from the count.

The modify data tape routine has five options. The first option merely prints out the contents of the arrays. The second option (263 through 276) inserts a new record into the file. First, the user types the information in, then the computer moves all of the records after where the new one is to be inserted up one record number. The new record then is put in the hole left by the records moved.

The delete routine merely moves all of the records above the record to be deleted down one. This destroys that record by writing over it. The program checks to make sure the user does not try to delete records that do not exist.

The fourth option (283 through 289) just outputs the arrays to the tape recorder, using a similar approach to the way they are read in. The fifth option is merely a jump to the menu.

The menu is straightforward, using an ON/GOTO statement to branch. Line 326 takes care of inputs that are not covered in line 325.

The calculations subroutine calculates the distance to the transmitter (lines 2001 and 2005), bearings to the transmitter, and directions to the transmitter (lines 2006-2220). The subroutine is made up of different branches used to correct the ambiguity of the ATN function.

It is hoped that this program and the presence of a good RDF committee will reduce the amount of jamming and be a valuable tool in locating emergency locator transmitters quickly. ■

Variable List

A—First coordinate of station A's location
B—Second coordinate of station A's location
C—Bearing to transmitter from station A
D—First coordinate of station B's location
E—Second coordinate of station B's location
F—Bearing to transmitter from station B
G—First coordinate of transmitter's location
H—Second coordinate of transmitter's location
L—Maximum report range
M—DIMension of arrays
P—Dummy variable for pausing program
Q—Menu selection
R—Number of stations within given radius of transmitter
S—Horizontal distance between a station and transmitter
T—Vertical distance between a station and transmitter
U—Distance from transmitter
V—Line counter in listing
X—First coordinate of station's location when using calculation subroutine
Y—Second coordinate of station's location when using calculation subroutine
Z—Bearing to transmitter
DR—Record number to be deleted
DF—Data flag
FR—Former record number
NN—New number of record after being renumbered
NR—New record number (inserted record number)
Q1—Option selection under option 5
RN—Record number
TR—Total number of station records in arrays
A$—"EAST" or "WEST"
B$—"NORTH" or "SOUTH"
G$—"Y" or "N" to load data tape at beginning of program
H$—"Y" or "N" to "DF-COMMITTEE MEMBERS ONLY?"
D$—Station's call
E$—Station's telephone number

Shack from Scratch

Building a ham shack in a new home can be a breeze. Just plan ahead.

Thomas R. Sundstrom W2XQ
Box 175
Vincentown NJ 08088

A man's home may be his castle, but have you tried to install a 6-element, 20-meter beam on a parapet lately? Most homes built or renovated today are not conducive to installing an amateur radio station.

The problem of what to do with the radio equipment confonted me when my wife and I opted to have a new home built in a semi-rural area. In our old home on a suburban lot, it had been make-do in a third bedroom with the attendant problems of running antenna feedlines, supplying adequate electrical power, and establishing decent grounds for the equipment.

My solutions will not necessarily be your solutions, but variations of these ideas may help you in solving your installation problems. Funds were a consideration—the overall objective was, after all, to build the house! But when it was all done, I wound up with a fair amount of operating room, all the electrical power I needed, and a TVI-free environment for less than two percent of the total cost of the house and property.

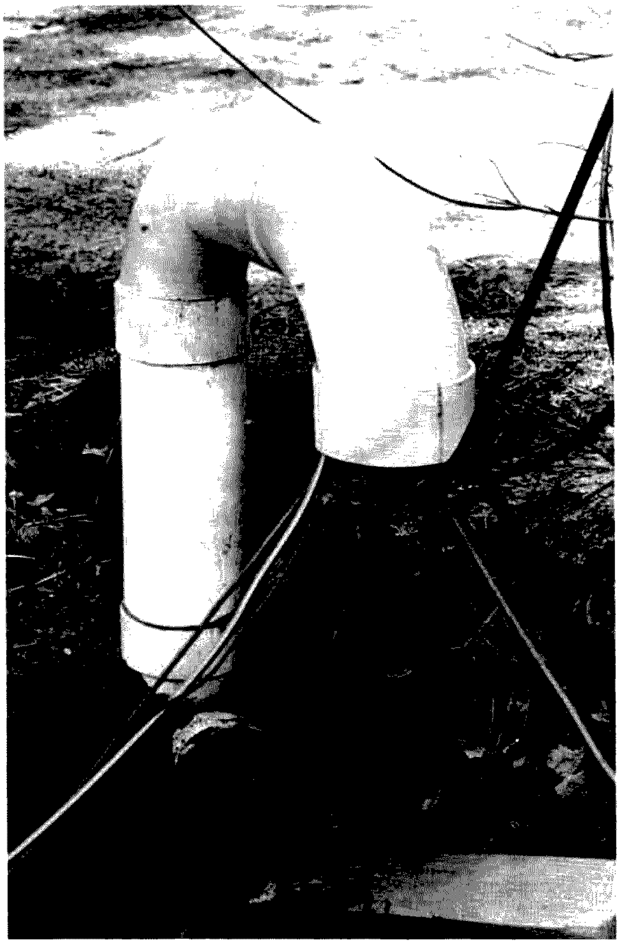

Photo A. The PVC pipe has a couple of elbows on the end of it to keep out rain and snow. A pull rope is left in the pipe to move additional antenna and rotor cables through; otherwise, the open end is capped and covered with dirt.

Review the Plans

Once you have selected the location (no zoning restrictions on towers, right?) and a builder, look over the plans carefully to determine options for the radio room.

In our case, the locale dictated no basement because of the water table. We chose an L-shaped ranch on a slab of concrete. The options were to put the equipment into a bedroom or in the back of the garage. Neither option was desirable.

The solution was relatively simple. The garage was on one end of the house on the long side of the L. We had the builder expand the long side of the L by adding a 6-foot-wide room between the living area and the garage and adding one wall and door. See Fig. 1.

The additional room provided space for the amateur radio equipment, enabled my wife to get the washer-dryer out of an interior closet in the living area, and gave us a mudroom in which to leave boots, raincoats, and other items that should not be trailed across carpeting.

In solving your installation problem, factors to consider would be (1) accessibility to the back yard (or the side yard) for antennas, with a minimum feedline run, (2) keeping the station away from the sleeping areas of the house so that

late night and early morning DXing sessions don't disturb the rest of the family, (3) keeping the family TV antenna, TV, and audio equipment apart from the radio equipment, and (4) the location of overhead power lines coming into the house.

If you opt to expand the house or add an addition to solve the location problem of your equipment, you can hold costs down by doing it in such a way that no new corners are created, needing additional forms for concrete and framing. For example, it would have been more costly for us to tack a room on to the back of the garage, extending that by 10 feet or so. Additional costs would have been incurred for laying forms around two additional corners, a redesign of the roof and supporting rafters in that part of the house, and a reconfiguration of the heating and cooling systems; considerably more concrete, lumber, and siding would have been needed.

Antenna Feedthroughs

Because space for antennas was available in the back yard, I agreed not to punch holes in the sides or roof of the new house and to see that everything was put in the back and out of sight.

Before the slab was poured, I had the builder lay down 4-inch PVC pipe extending from beyond the foundation of the house to the rear of the proposed station operating area. A 90-degree elbow and a short section of pipe at the desk end put that end above the floor level. The poured concrete anchored the 10-foot sections; a board temporarily capped the end outside the house.

Later, I purchased additional sections of PVC pipe and extended the run further into the backyard, bringing it above ground beyond the normal traffic patterns and behind some ground cover. Two 90° elbows are needed so that rain and snow do not enter the pipe. See Fig. 2.

In retrospect, I probably should have put two runs of PVC pipe into the shack area. While one handles a number of RG-8 and RG-8/X and control cables, hardline takes up a lot of room in a hurry.

Factors to consider in planning your own installation include (1) keeping runs of PVC pipe as straight as possible to minimize difficulties in routing cable, (2) leaving a "pull" rope in the pipe so that cable can be fed through from either end at any time (and don't forget to anchor it so that it's not accidentally pulled into the pipe beyond your reach), and (3) consideration of how many antennas and types of feedlines will be installed in the coming years.

Variations on the theme of using PVC pipe to route cable might include using PVC pipe inside the house to route cable to an exterior wall. Place the pipe inside the walls before the sheetrock is hung. Depending upon the design of the house, you may choose to route the pipe and cable to the attic from an interior first- or second-floor room chosen as the "shack," or route it to the basement or the garage before entering the underground run to the antenna tower.

Another variation, for those setting up the operating station in a basement or family room below ground level, would be to bring the PVC through the exterior wall to a point flush with the inside wall. Make up an appropriate bulkhead with connectors and label the lines. In times of electrical storms, shorting plugs can be put on each of the antenna feedthroughs and grounded through the ground attached to the bulkhead plate.

Photo B. The PVC pipe comes up under the operating desk. One of the two ground rods is visible on the right.

Grounds

At the same time that the PVC pipe was laid for the antenna cable runs and before the floor was poured, I installed 10-foot, ¾-inch ground rods at the rear of the area where the operating desk was to be placed. I left them about 8 inches above the finished floor.

That simple move has paid off handsomely in the reduction of in-house TVI and RFI on the operating desk compared with what I had been used to in the previous house. Ground leads are a maximum of 3 feet now.

In your installation, consider the shortest run possible. If you are setting up in an interior room, drop the ground leads through the walls directly to the basement. Use ground rods as long as possible; those 4-foot lengths just won't do the job. Run heavy wire; #4 would be fine. As the heavier wire is a bit difficult to work with, consider tying the heavy ground lead to a heavy-gauge metal plate that has been drilled and tapped with 3/8- or 1/2-inch bolts and place that behind the operating desk. The individual ground leads from the several pieces of equipment can be terminated with spade lugs and bolted to the plate.

Electrical

Before the wall between the added utility room/ham shack and the garage was closed, I had an electrician wire a separate electrical panel for the radio equipment. At the main electrical panel in the garage, a 70-Amp circuit breaker was installed. A three-wire line was run into the shack wall; another panel was installed with a 70-Amp main circuit breaker, and separate circuit breakers were installed to provide 220 and 110 V ac to a number of outlets.

Perhaps this was overkill, but the family members have instructions on how to turn off either main breaker in case of an emergency. Everything goes down when

that switch is thrown. (That panel is low enough for even my youngster to reach.)

Plan your needs carefully. I had eight 110 V ac outlets installed, and still I ran out. Also consider height and placement of the outlets. Don't install outlets at tabletop height if the surface of the operating area runs wall-to-wall; put them above or below the tabletop.

Odds and Ends

Some other planning-ahead activities to consider as the house is framed and before the sheetrock is hung are all based around pre-wiring the house for a variety of items.

Don't forget to get the telephone installer at work before the sheetrock goes on. The job is a lot easier and cleaner. Run a telephone line into the shack, and consider having the house wired for two (or more) telephone lines. If you change your mind at the time the installer returns to fish out the lines to telephone jacks, there is no problem reverting to one line. There is no charge for pre-wiring the framed house.

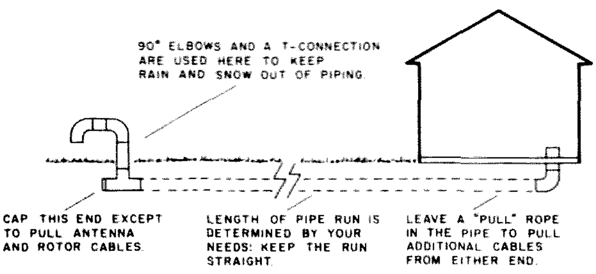

Fig. 2. Details of PVC pipe arrangement which contains coax and control cables.

Want to install a burglar alarm system? A wired perimeter system tends to be the cheapest, and it's easy to do yourself. Supplies can be acquired from a number of wholesale and retail outlets. Pick the system best for you; it may be easiest to install before the walls are closed. Don't forget about electrical power to the system (most systems also have a battery backup).

Also consider pre-wiring for your stereo system. It's a lot easier to run speaker leads in the walls and over ceilings than under rugs or behind wall moldings. Use some larger-size electrical zip cord, such as #12 or #14, rather than the light stuff. Plan ahead for the day when you upgrade to a larger, more powerful amplifier and have speakers in other areas of the house. You can always leave the wires in the walls until you actually have speakers in hand.

An intercom system is also very easy to put in before the walls are closed. Plan ahead. (It's your choice to put one in the shack so that you can be called to do chores in the middle of a contest!)

Be sure to install 75-Ohm coaxial cable for the household TV and FM antenna system before closing the walls. Consider the placement of the antennas with respect to the ham equipment when routing the cable. I opted to install an antenna to take care of both the TV and the FM stereo receiver under the roof of the house, rather than outside, and hung it in the end of the house away from the shack. Plan ahead if you want multiple outlets for multiple TV sets, and don't forget an electrical source for a distribution amplifier if your plans require one. Using shielded cable and picking the right spot for your TV/FM antenna(s) will go a long way to eliminating in-house TVI.

I also took advantage of the open walls to install a coaxial cable which was later hooked up to an attic-mounted scanner antenna and a scanner in the family room; my wife and I eavesdrop on one or two police and fire frequencies, some remote broadcast stuff, and one or two 2-meter frequencies.

In Closing

The building of a new home or of a major addition to an existing home is a massive undertaking. Attention has to be given to everything, and the smallest detail has to be reviewed on a continuing basis. If you tell the builder *before* he begins that you want to install certain wires and pipes for the amateur radio station, there shouldn't be any problems. In my case, the builder gave me a schedule of construction and permission to come in to install the ground rods and the pre-wiring described above; he placed the PVC pipe for me, and the electrician came after I took title to the house.

Keep receipts on everything you purchase and install. That's all part of your tax records for calculating the adjusted cost of the house and the improvements, depending upon the dates involved.

Some of the ideas described above are not necessarily new or original, but they are intended as food for thought. Your needs are different from mine, but if I have reminded you to think about a particular installation problem before you begin a project, then I have been successful. Good luck in your building. ■

Winning the Coax War

The electrical length of feedline depends on its velocity factor. Don't get caught short.

Paul Swearingen W9PJF
RR #1, Box 485
Benton IL 62812

A review of the basic theory sections of many radio handbooks will reveal references to "dielectric constant" and "velocity factor" as interrelated characteristics that describe real-world influences upon the velocity of an electromagnetic wave and upon the capacitance existing between two conductors.

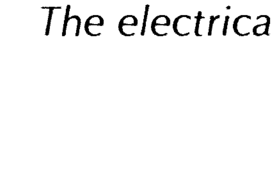

Fig. 1(a).

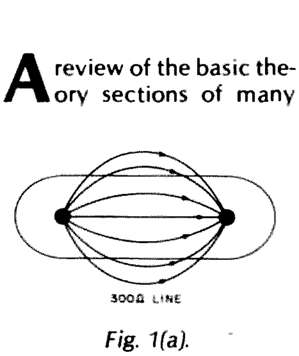

Fig. 1(b).

We don't need to be physicists or to even understand the actions of dielectric molecules to observe that capacitors come in a variety of sizes and shapes. The basic capacitor consists of two conductors separated by an insulator. When the capacitor is charged, the insulator becomes a dielectric because it is then permeated by the electric field between the conductors.

The value of the capacitance depends upon the area of the conductors, the spacing between them, and just what sort of dielectric occupies that space. For example, two sheets of aluminum about 3′ on a side and spaced about 3/16″ apart in a vacuum would form a capacitance on the order of 1500 micromicrofarads, or 1500 picofarads as some may prefer to call it.

If the vacuum between the plates were replaced with glass, the capacitance might increase by a factor of 5 to a new value of 7500 pF. The factor "5" in this case would be the "dielectric constant" of that kind of glass. The thickness of the metallic plates has little effect on the capacitance. For the smaller capacitance values with increased conductor spacings, the "edge effect" requires consideration. This effect is a result of non-linearities in the electric field near the conductor edges. Manufacturers use a variety of dielectric materials to produce the capacitors for today's electronic systems.

Radio signals and other electromagnetic waves travel at a velocity of about 300×10^6 meters per second in a vacuum and just a bit slower in air. This velocity of propagation is equal to about 186,000 miles per second. In liquid or solid materials, the velocity of electromagnetic waves is decreased by an amount depending upon the specific characteristics of the material. A signal travels a distance of one wavelength through space in a period of time depending upon its frequency. Under the (ugh!) metric system, the formula for a wavelength (λ) in space is: λ(meters) = 300/frequency (MHz). In terms more familiar to some of us, a free-space wavelength (λ) in feet is equal to 984/frequency (MHz).

If the same signal had to

travel through glass having a dielectric constant of 5, the distance it would move during the time period of one wavelength would be much shorter. In fact, one wavelength would be only 44.72% of the equivalent length in space. When converted to a decimal figure, .4472, this dielectric correction is the "velocity factor" (VF) of the glass. It is equal to the reciprocal of the square root of the dielectric constant or VF = $1/\sqrt{5}$ = 1/2.236 = .4472. This formula describes the mathematical relationship between "dielectric constant" and "velocity factor."

So, what can we do with dielectric constants or velocity factors? Actually, I can think of very few occasions when changing the dielectric in a capacitor would be necessary, desirable, or feasible. It would be fairly easy, though, to make a low-capacity variable capacitor by using two pieces of aluminum and to insert a variable amount of a plastic dielectric via a shaft and a dial system.

The velocity factor, though, is a much used and occasionally misused factor.

All of the coaxial and parallel-wire feedlines using solid dielectrics are characterized by higher losses than found in equivalent air-insulated lines and by having velocity factors of less than 1. These velocity factors mean that radio waves are propagated along these lines at velocities less than in free space. When the electrical length of the feedline to be used is critical, the velocity factor must be considered in calculating the physical length. If you wanted an electrical length of 1/2λ and the velocity factor was .80, then the desired formula for the physical length in feet would be: 1/2λ = (492 × .80)/frequency (MHz).

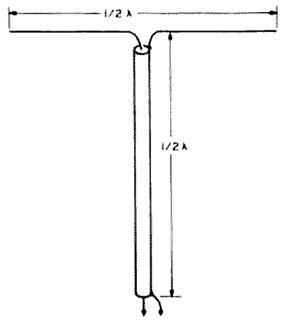

Fig. 2(a).

The velocity factors for some common coaxial feedlines range from .80 for polyethylene foam dielectrics to .66 for solid polyethylene. Some 300-Ohm parallel-conductor feedlines using a solid dielectric of polyethylene have a velocity factor of about .82. Why should that be? Fig. 1(a) shows a cross-sectional view of a piece of 300-Ohm line. The oval represents the solid dielectric and the dots represent the conductors. The arrowed lines represent an instantaneous electric field that might exist at a given moment in time. The fact that a portion of this field exists outside the solid dielectric is the reason that the 300-Ohm line velocity factor of about .82 lies between the .66 factor of solid polyethylene and the value of 1.0 for air. This also explains the sensitivity of oval 300-Ohm line to external influences such as rain, snow, and ice, or to the proximity of metallic objects.

Fig. 1(b) shows the cross section of a 100%-shielded coaxial cable. In this case, the electric field is wholly contained within the shield, and surrounding influences are minimal. That's why coaxial cable can be taped to your tower, run along gutters, or even buried with little observable effect upon its performance.

The velocity factor is used to determine the physical length of the line whenever a particular electrical length of feedline is required, and when in the feedline's use an electric field will exist between the feedline conductors as a result of current flow along the conductors. Fig. 2 shows some of the typical cases wherein the velocity factor would be used in calculating the physical length of the required feedline. In Fig. 2(a), a feedline 1/2λ long is used so that the impedance at the center of the antenna will be repeated at the ground end for easy impedance measurements. The desired physical length of a 1/2λ line would be the free-space length times the velocity factor, or 1/2λ (ft.) = (492 × VF)/frequency (MHz). In this case, the line could be made any whole number multiple of the correct length if a single 1/2λ wasn't long enough.

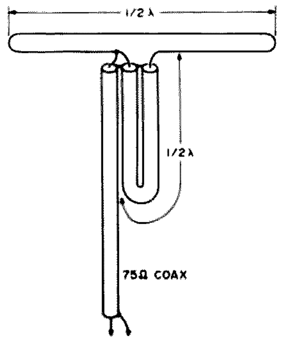

Fig. 2(b).

Fig. 2(b) shows a 4:1 coaxial balun connected to a folded dipole radiator. The length of the 1/2λ U-shaped piece of coax is calculated with VF. Fig. 2(c) shows broadside radiating elements, each fed through a gamma match. Any equal lengths of cable could be used for pieces X and Y to satisfy the phasing requirements of the broadside array. The 3/4λ sections, however, also serve as impedance transformers between the radiators and the feedline junction. The physical length of the 3/4λ lines should be computed with the VF.

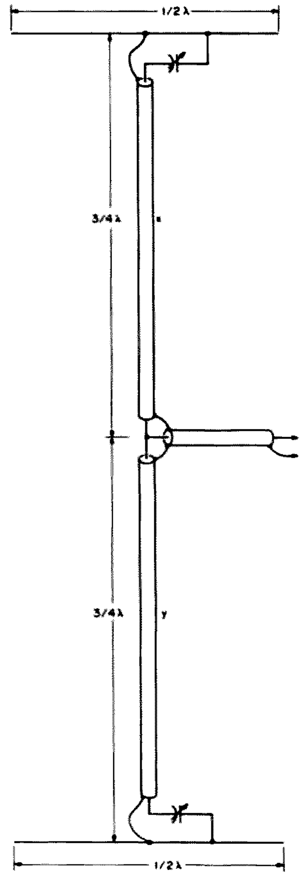

Fig. 2(c).

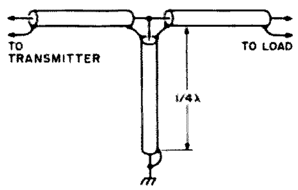

Fig. 2(d).

Fig. 2(d) shows a 1/4λ section of coaxial cable used as an rf choke. The shorted end of the 1/4λ section is transformed into a very high impedance at its connection point to the coaxial feedline. It has no effect upon the feedline as far as the operating frequency is concerned, but it keeps both sides of the coax at ground potential for dc or lightning protection. In addition, the 1/4λ section will act as a dead short across the coaxial cable at the second harmonic!

Fig. 2(e) shows 1/4λ ver-

Reader Service for facing page ✓83→

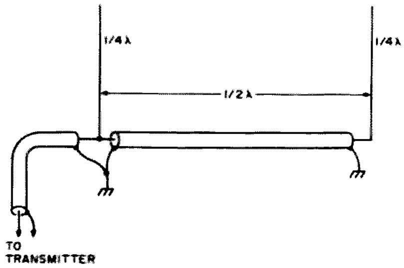

Fig. 2(e).

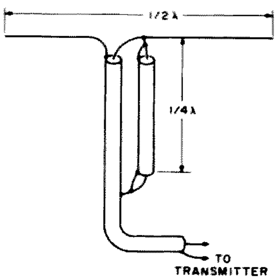

Fig. 3(a).

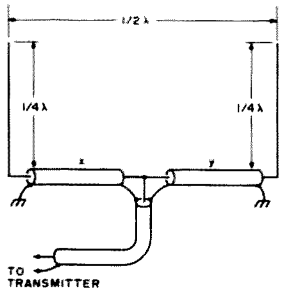

Fig. 3(b).

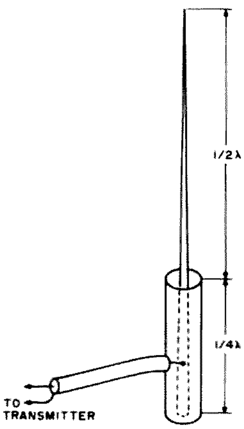

Fig. 4.

tical antennas spaced 1/2λ apart and fed 180° out of phase through a 1/2λ line to achieve a figure-eight radiation pattern. Fig. 2(f) shows similar antennas spaced 1/4λ apart and fed 90° out of phase to produce a unidirectional pattern. The velocity factor would apply to these phasing lines. Please note that Figs. 2(e) and (f) are just basic representations of an antenna system and not a practical arrangement.

How could you make a 1/2λ of coax (free space 1/2λ × VF) stretch between two verticals spaced a 1/2λ (free-space value) apart? It would be impossible unless you used an *air-dielectric* coax and then, of course, its proper length would be equal to the antenna spacing.

The proper phasing with solid-dielectric coax can be achieved as shown in Fig. 2(g). Dimension X is any convenient length of coax. The 1/2λ portion is computed with the VF. While this feedline system provides the proper phasing, it doesn't provide the necessary impedance matching. The same scheme could be used to provide the correct phasing for Fig. 2(f), but then the lines would be X, and X + 1/4λ.

Fig. 3 shows some cases where the velocity factor is *not* used in determining the physical length of solid-dielectric cables. In Fig. 3(a), a 1/4λ of coaxial cable is paired with a portion of the feedline to act as a decoupling stub or balun. Its length is approximately equal to the free-space length of a 1/4λ. The VF of the coax does *not* apply because no electric field exists between the inner conductor and the shield of the 1/4λ of coax. In fact, the inner conductor could be cut off flush with the dielectric, or even removed, as it has no function in this application other than to provide increased physical rigidity. In Fig. 3(b), line segments X and Y could be of any equal lengths and still provide the correct phasing for the broadside array. VF does not apply because a particular electrical length of feedline is not required.

The effects of velocity factor/dielectric constant in places other than feedlines can sometimes be important to the correct functioning of antennas or resonant circuits. For example, a coaxial version of a "J" antenna is shown in Fig. 4. The lower 1/4λ could be an air-insulated high-Q resonant section which matches the high end impedance of the 1/2λ radiator to the coaxial feedline.

This is a good, simple antenna for VHF. If it were to be built, though, you might be tempted to fill the lower 1/4λ section with plastic potting compound for improved physical rigidity or to minimize the effects of weather. Any dielectric added, however, would change the electrical length of the section, thereby detuning the system. A better approach would be to use the velocity factor of the plastic filler beforehand to determine the correct length of a plasticized 1/4λ section.

Why have I persisted in using the free-space formulas times the velocity factor to compute specific physical lengths? What's wrong with the old, tried and true formula, 468/frequency (MHz), to find the length of a 1/2λ? The reason is that antenna design is influenced by something called "end effect." This necessitates just about a 5% reduction of the free-space lengths when calculating the physical length of wire antennas. This phenomenon does not occur in transmission lines, so for these applications we just have to adjust the free-space figures with the velocity factor.

There is no doubt that coaxial cable is the most-used amateur feedline today. Its ease of use more than compensates for its small losses. If you need a critical electrical length, however, don't forget to use the velocity factor established by the cable manufacturer. ■

Red-Hot and Ready to Go

Anyone who has ever soldered knows that the cord gets in the way. Find freedom with this home-brew cordless iron.

Here's a simple, one-evening project that has proved to be very worthwhile. The end result is an instant portable soldering iron that is heavy enough for most soldering jobs short of antenna and chassis work. Since the tip can be changed from high to low power, the battery life may be extended when only light duty work is involved.

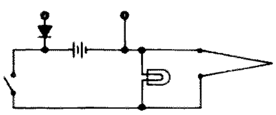
A 6-1/2" × 2" × 1-5/8" box neatly holds the parts, which consist of two size D nicads, two barrier strips, an on/off switch, a pilot lamp, a replacement soldering gun tip, and a diode to facilitate recharging the batteries. The pilot lamp is a #222 (2.25 V, 0.25 A).

Do use the lamp, as it is a very practical visual voltmeter and will give an indication as to when the battery needs a recharge. The tip still will get hot even if one of the cells is run down, and that can lead to deep discharge of the cell. Besides that, the lamp helps you to see where the solder is supposed to go inside of those dark and mysterious projects. (With 3.5-Ah cells and the tip removed, the thing makes an excellent 14-hour emergency flashlight.)

Without a doubt, there are better ways than the one shown to secure the tip, but this method is adequate and allows the business end of the instrument to get into tight places. If you wish to duplicate this mess, use a convenient length of #12 wire. The two-inch length shown has a voltage drop of about 10 millivolts per leg.

The heavy-duty tip, Wahl #7546, draws 8.5 A at 2.5 volts. The regular tip draws 6.5 A. With that kind of current, it is no surprise to find less than 2.5 V at the tip. The measured voltage is close to 2.1. The batteries fell to 2.25 volts.

With that kind of current, the on/off switch must be a heavy-duty type. The least expensive on/off switch that I could get happened to be a push-on/push-off type. Since the iron stands by itself, this allows both hands to be used for bringing the work to the iron—which is often the most convenient way to do it. With the lamp glowing and the point smoking, you are not likely to go off and leave the thing turned on.



REPLACEMENT SOLDERING GUN TIP
#222 PILOT LAMP
SOCKET FOR LAMP
ON/OFF SWITCH
SIZE D CELLS 1AH OR 3.5AH
BARRIER STRIP
BOX
1N4001

Fig. 1.

A quick word concerning the batteries is now in order. With 1.2-Ah size D cells, expect about 8 minutes operating time. Allowing 10 seconds to reach operating temperature and another 10 seconds to make the connection, that would figure out to be about 25 connections (that's the high-power tip). With 3.5-Ah batteries, the arithmetic says to expect about 73 connections. The lighter tip should give about 23% more operating time.

Instant soldering iron.

The batteries may be recharged by means of a suitable current source connected to the second barrier strip. The battery manufacturers normally state on the battery how much current should be used and for how long. The diode is included to ensure that the current is not fed in backwards.

Since this is a cordless iron, there is no cord to use for storing solder. (You do keep a chunk of solder on your regular iron handle or cord, don't you?) The way the solder is stored here ensures an adequate supply and is almost self-feeding.

All of the parts for this project, except the batteries, were purchased new! (Don't faint!) The heavy-duty 3-4 Ah nicads are quite expensive if purchased from the regular wholesale outlets, so try to get them from one of the surplus sources.

The unit has proved itself after many hours of reliable operation. ■

Cutting Current to Size

Measuring large ac currents can be difficult unless you know a trick or two. W7CRY explains how.

Larry T. Wier W7CRY
1068 149 Pl. SE
Bellevue WA 98007

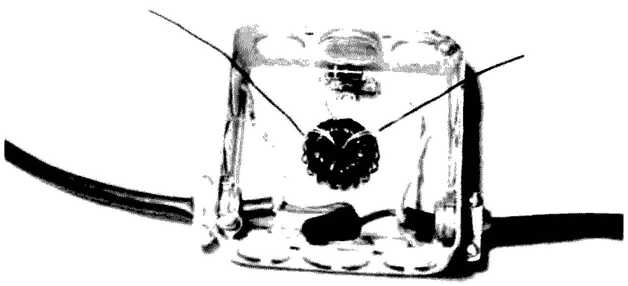
Have you ever tried to measure large ac currents and found your trusty VOM somewhat short? Welcome to the club. I was stuck with the problem of finding the current used by an electric hot water heater but no way of measuring it.

I also found my wallet short after letting my fingers walk through several instrument catalogs. Several hours of thrashing around the workbench yielded a simple and, best of all, inexpensive way of measuring large ac currents using an ordinary 88-mH choke, a trick or two, and Ohm's law.

Theory

Perhaps a little transformer theory should be covered before Ohm's law and the tricks are applied.

By definition, a transformer is exactly what its name implies: It transforms one voltage (or current) to a different level. The major differences between a voltage transformer and current transformer are the turns ratio and power-transfer characteristics. Depending on design, the voltage transformer has a low turns ratio, i.e., approximately 19 to 1 (118/6.3) for a filament transformer. The current transformer, on the other hand, has a turns ratio from around 300 to greater than 10,000 to 1, depending on the burden (load) on the secondary.



The almost-completed ac current transformer. The transformer is mounted on a piece of styrofoam™ which is glued to the box. Contact or rubber cement can be used for both the foam and transformer. The signal wires (not shown) can be routed out through any of the knockouts.

The current transformer always has the burden specified along with the current ratio. For example, a typical 50-Amp to 5-Amp current transformer will require a burden of .25 Ohms. If the secondary burden were to open or be removed, the transformer would be destroyed because the voltage developed across the resulting open circuit would cause arcing within the windings.

An additional consideration is that the current transformer should not introduce significant changes in the circuit being measured.

Hybrid Current Transformer Design

Fig. 1 shows the basic technique in utilizing the 88-mH choke as a current transformer. The term hybrid is used because in using the choke, a "halfway in-between" turns ratio will result. The approximate number of turns is determined by measuring the resistance of the coil, finding

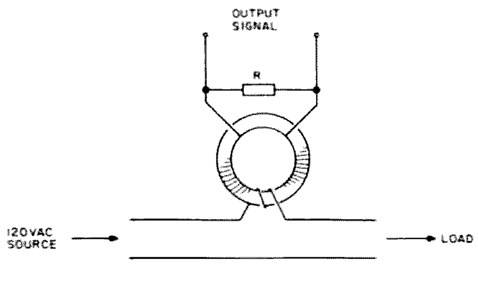


Fig. 1. Basic hybrid current transformer.

Reader Service for facing page ✓ 303→

the wire size, and, from a wire table, finding the resistance per foot. By taking the average diameter of the donut and average cross section, a rough turns count can be calculated.

For those not willing to take the time to play with the math, a quick test can be found in the calibration section. If the ratio is found to be in excess of about 300, the choke is a good candidate.

Apparently, there are several so-called surplus 88-mH-type chokes. I found some with and some without center tap. I have also found some with two separate windings. These can be used if the windings are connected in series adding. Even though the choke defined here was intended for the audio frequencies, it works well at 60 Hz if the power levels are kept low.

Construction

The only construction required is covering the existing windings with tape. Once the value of R is determined, it can be soldered to the windings and taped to the body of the coil or mounted as shown in Fig. 3. The signal wires are attached across the resistor and routed where necessary. Wire length is not critical, but wires should be routed away from high-noise areas.

Calibration

Fig. 2 shows the test setup used to calibrate the current transformer. It is not necessary to use the 120-volt, 60-Hz line to do the calibration. As shown, a low-voltage, high-current voltage transformer with an adjustable input is the quickest and safest.

For calibration purposes, R can be a quality pot. The 100-Ohm resistor is used to prevent shorting the transformer, but is part of the burden. The source and load will depend on what is available. Use the following steps to calibrate the transformer:

1) Make sure that there are ten complete turns of #18 insulated wire wound as shown in Fig. 2.

2) Adjust the load for 10.0 Ohms.

3) Adjust the voltage to the load for 10.0 V ac.

4) Adjust R (1k pot) for an even value of voltage—preferably 0.1 V ac. Remove power.

(If 0.1 volt was not obtainable, replace R with a 2k pot. If the measured voltage was higher than 0.1 V ac, set the value to any even value above 0.1 V, e.g., 0.3 V ac.

(The current ratio is calculated as follows: $I=E/R$, where E was set to 10.0 V ac and R was set to 10.0 Ohms. Therefore, $I=10\ V/10\Omega=1$ Amp.

(Then 1 Amp through 10 turns equals 10 Amp/turns which is also equal to 10 Amps with 1 turn through the transformer. With one turn in the primary and the measured value across R of 0.1 V ac, the ratio becomes 10 to 0.1. By Ohm's law, E is equal to I times R, and if R is held constant, then E must be proportional to I.

(What this boils down to is that the current through the transformer will generate a proportional voltage across R as long as R stays constant. If the ratio has been set correctly, adjusting the load to 1.0 Ohms and again adjusting the voltage across the load to 10.0 V ac, a value of 1 V ac should be measured across R.)

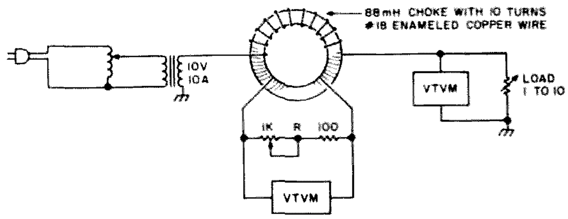

Fig. 2. Calibration test setup.

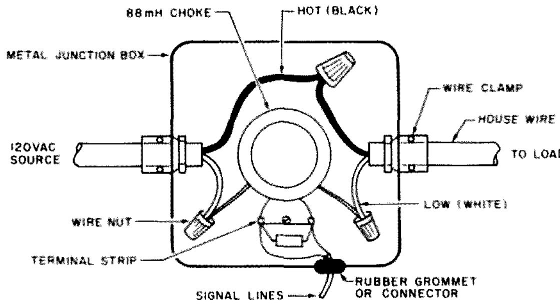

Fig. 3. Mounting fixture.

5) Determine the wattage for R by measuring the value of R and calculating as follows: $P_{Watts}=E^2/R$. Generally, a ½-Watt resistor will be more than sufficient. Replace the pot and 100-Ohm resistor with a fixed value equal to the combination of the two in series.

Application

Obviously, this combination can be used with any current range. It is limited only by the size of wire capable of being wound (1 turn) through the donut. Note that at least one turn is necessary to excite the transformer core. Passing the wire through the hole is not sufficient. Practically speaking, a #5 (solid enameled) wire is about the maximum-size wire which can be formed into one turn around the donut. This limits the upper current range to around 50 Amps.

The number of turns wound on the current transformer will depend on the current range to be measured and wire size. As an example, suppose a motor rated at 15 Amps (running) is to be monitored. We know from our calibration that 10 Amps gave us 0.1 V ac across R. Therefore, one turn of #12 wire through the donut should give us 0.15 V ac across R. The #12 was chosen because it is the smallest size generally used for motors in this range.

Another example is the case where only 1 Amp is to be measured. In this case, the wire size (assumed to be #14) is too large to pass a large number of turns through the donut. If you can assume also that nothing larger than approximately 5 Amps will be

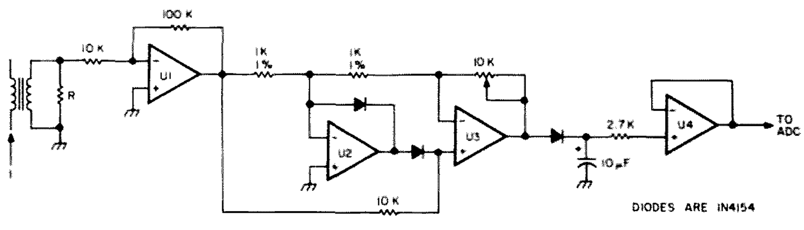

Fig. 4. Precision rectifier/buffer.

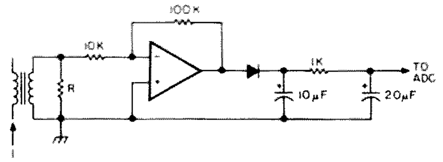

Fig. 5. Half-wave rectifier.

passed through the donut, then ten turns of #18 (solid enameled) will generate 0.1 V ac across R. In most cases, the number of turns will be determined by the measurement requirements.

Installation

According to most electrical codes, any splices of power lines must be located in a box. An outlet or junction box will work equally well. The transformer should not touch the metal box, and make sure that only the circuit being measured is in the box. It is best to use the low side (white wire) because the voltage between the low side and ground will not exceed the voltage rating of the enameled wire.

When measuring a 220-V ac line it will be necessary to use either of the two hot (red or blue) lines. In this case, the donut should have at least one layer of electrical (plastic) tape between the two sets of windings. Fig. 3 shows one method of mounting the donut and resistor R. Any method which meets your local code requirements will work.

Use

Now that you have a current transformer, how can it be used? The answer to that depends on why it was built. The easiest use of the current transformer is with an ac voltmeter. In my case, it is being used in a computer-controlled power system. Since a computer does not know ac from dc (or much else), the ac signal across R must be signal conditioned. There are many ways to signal-condition, but the method I chose was determined by the analog-to-digital converter (ADC) used with my computer. It has ±15 V dc available, so that the use of operational amplifiers seemed to be the best solution.

Fig. 4 is an example of how the ac signal is conditioned from ac to dc for the ADC. It is beyond the scope of this article to dissect the operation of Fig. 4 except to note that U2 and U3 form an absolute value (precision-rectifier) circuit. U1 is an inverting amplifier and U4 is used as a unity-gain buffer. U1 and U4 are in one LM747 and U2 and U3 are in another. Any general-purpose operational amplifier will work. (More information on this particular absolute-value circuit may be found in the November 8, 1979, issue of *Electronic Design*, page 94.)

A simple amplifier and diode arrangement also will work if accuracy and response time are unimportant. Fig. 5 is the method used in this case.

Summary

No matter what the requirement, a simple arrangement such as described here will provide a reasonably accurate measurement of ac line current. Sources of 88-mH chokes are found in the back of most electronic magazines and cost around $3.00.

Now I need to look into a method of measuring the gas pressures in my heat pump! ■

Construct This All-American Audio Signal Generator

The perfect project for starting a test bench or rounding one out.

It is still possible for the average builder to design and make equipment that is competitive in cost and effectiveness with that which is store-bought. Many simple, standard design concepts can be applied to modern technology.

The Circuit

This FET audio signal generator is an easy project derived from the audio oscillator circuit presented in "Working with FETs—part 1," in *73* in November, 1979. There are some simple additions in the finished circuit which make it far more useful than just the basic circuit (see Fig. 1).

I could have used a switch and a selection of fixed values, but it would have cost more and built in a fixed limit. The easy way out was to put the frequency-determining capacitor outboard so that it can be changed quickly. You can use a substitution box or your junk-box selection with ease, but most of the time you can just leave the fixed value in place. I have rarely needed more than the one tone for testing.

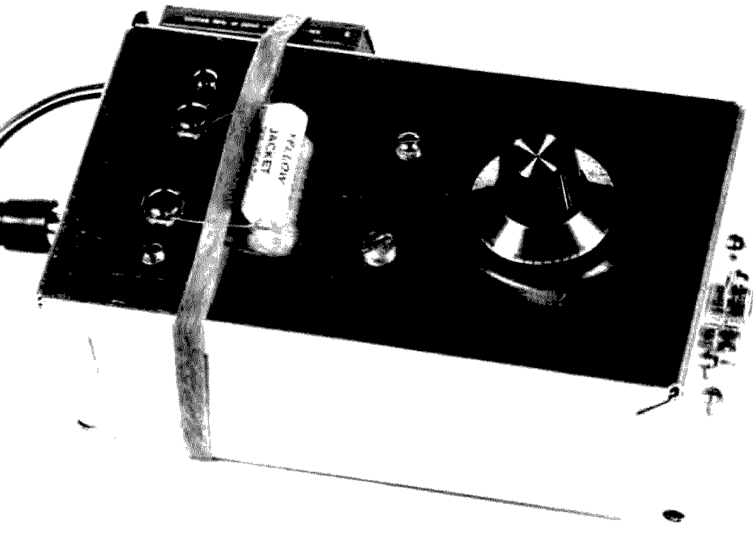
Potentiometer R2 gives you an adjustable output level. This is very handy for testing or troubleshooting. Resistors R3 and R4 form an output attenuator network that gives you a low-level adjustable output. This is useful when working with high-gain circuits. Using an attenuator network gives you a cleaner low-level signal than trying to use a high-level signal at the lowest setting.

A 9-volt transistor radio battery or a power supply can be plugged in at J3. This way you can change quickly between battery and fixed supply, or use your battery or supply with other equipment. It's handy. The low power drain, about 2.2 mA, makes this a really practical project for battery and portable operation.

There are only a few parts values that are at all critical. The design center was for 10% tolerance and in most cases it is much wider. Except in one important case, the voltage rating is anything reasonable over 20 WV dc.

L1 is an 88-mH unpotted toroid. It is a common surplus item, but you may have to look around. They are often used for filters in RTTY equipment.

C1 in combination with L1



Top view of FET audio signal generator.

is what actually sets the audio tone. My substitution box gave usable tones from 0.22 uF up, but the highest tones were out of the comfortable audio range. I think that 0.1 uF to 0.22 uF would be a good starting point. Get out the junk box and play around.

R1 limits the voltage swing of the output waveform at the gate of Q1. If it were not there, under some conditions the signal might be large enough to damage the transistor. The value is not critical; 3.3k or more will do, but have something there for protection.

Q1 is a Motorola HEP-801, a commonly available audio FET. It has four pins, the fourth being a connection to the outer case. When I made the prototype circuit, the matrix board automatically connected the case to the source pin. It worked well that way so I left it in the finished circuit.

Drain bypass capacitor C5 is not critical. Anything from 20 to 100 uF at 20 volts or more should do. The circuit worked well without it, but it might be needed to keep any noise from getting in from your supply. Keep in mind that to further decouple the circuit you can also add a 2.2k or so resistor in series with the drain line if you have a stubborn noise problem. The greater the capacitance of output coupling capacitor C2, the better the low frequency response. I used a 0.1-uF 50-V-dc disc ceramic that was on hand.

Output level control R2 is a 50k linear-taper potentiometer. A linear taper is used because it is a voltage divider application, not a true volume control. Mine has an ac switch (SW1) right on the back, but you can use a separate switch.

R3 (470k) and R4 (47k) form the attenuator network. The textbook values would be different, but since I aimed for a wide 10% tolerance, it worked out well. The measured output is very close to a 10:1 ratio. My resistors happen to be 5% values as they were available in the store. Output coupling capacitors C3 and C4 have the only critical ratings: Both are 0.01 uF at 1000 volts disc ceramics.

The voltage rating is critical. They block any dc voltage in the test circuit (such as a tube-type amplifier) from getting back into the generator and frying all the little parts. Use at least 500-volt capacitors, preferably higher. You should not be using equipment like this in really high-voltage circuits. It's unhealthy. But a good safety margin will keep you going when you work with most tube-type equipment.

These two capacitors also will determine the frequency response of your generator and it's hard to find high capacitance at high working voltage. This means that your lowest audio tones will have less output voltage than mid or high tones.

I should stress that the low-frequency loss comes from the coupling capacitors in the circuit, not the oscillator, which will provide far flatter output across the audio spectrum.

Construction

Construction is easy. There are only a few mechanical problems to watch for. The photos show the parts layout and there are a few tricks to make it easier.

I used cardboard at the top and bottom of toroid L1 and a short length of insulation over the screw where it went through the toroid to prevent any shorting.

There is one potential trouble area. Clean the enamel off the magnet wire ends of the toroid very carefully. I mean really get in there with a sharp penknife and *scrape it off*. I was sloppy the first time. It looked good but it didn't work. It took me a while to find the problem. Check for a good clean contact with your ohmmeter. It doesn't matter which end is grounded when you install it, but when you make the center-tap, look for the two ends that are closest together.

Use a good quality transistor socket. The cheap one I tried at first fell apart. I soldered the leads to the socket first and then wired it to the terminal strip. I was going to tack it down with silicone sealer, but the wire was stiff enough that it didn't wander.

RCA jacks were used throughout. They are not the last word in connectors, but they are cheap and easy to get.

There are many styles of enclosure available; it just has to all fit. I did not try

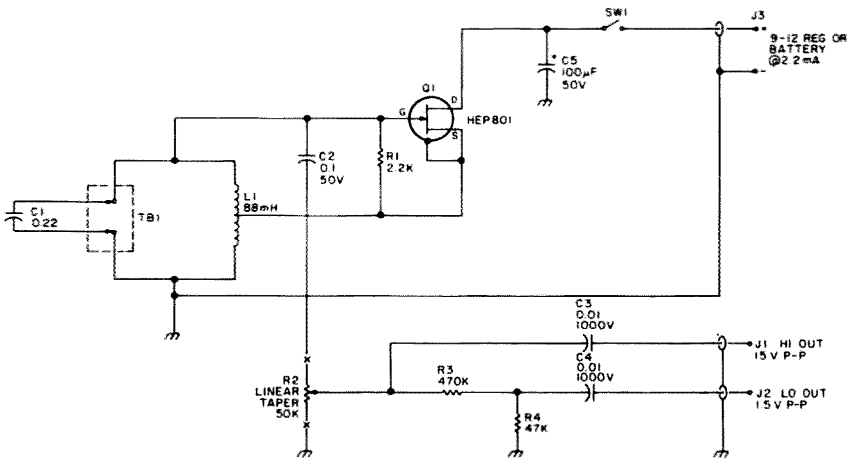


Fig. 1.

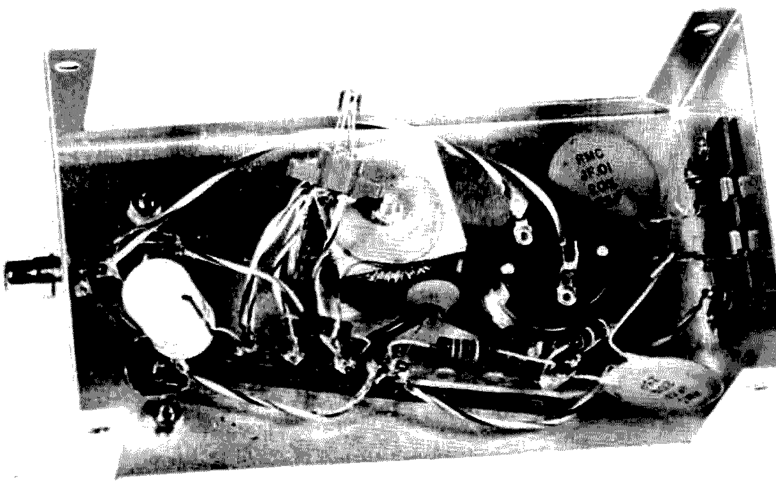
Parts List

C1—0.22-uF, 20-volt or greater
C2—0.1-uF, 50-volt disc ceramic
C3,C4—0.01-uF, 1000-volt disc ceramic (voltage rating critical)
C5—100-uF, 50-volt electrolytic
J1, J2, J3—RCA jacks
L1—88-mH toroid
R1—2.2k, ½-Watt 5 or 10%
R2—50k, linear-taper pot. (Radio Shack 271-1716)
R3—470k, ½-Watt 5 or 10%
R4—47k, ½-Watt 5 or 10%
SW1—ac switch, part of R2 (Radio Shack 271-1740)
Q1—Motorola HEP-801 n-channel FET

Miscellaneous

Minibox—5-1/4" × 3" × 2-1/8" (Radio Shack 270-238)
Knob—Radio Shack 274-413
TB1—2-screw terminal strip
Solder terminal strip (see photo)
Transistor socket
Mounting hardware



Bottom view.

to miniaturize. It's small enough now to be handy but large enough to service easily. Notice that the leads are not as short as they could possibly be. It's neat, but there is room and length to work with.

The only part that might be a problem to buy is the toroid. They are still common mail-order items if you check the RTTY supply houses. Get a few; they're useful. Almost any of the other parts are common enough that you may be able to use some of them to make up a minimum order requirement.

I spent a little under $9 to build the signal generator. I had the toroid, transistor, and some of the small parts, but I bought the rest new to get the prices. I would estimate that it can be built for about $12 if you are careful, and within $15 without too much trouble.

Testing

When you have it put together, check for wiring errors and shorts. Put your milliammeter in the power lead and check the current as you turn it on. Don't forget to put some capacitance value at TB1 (C1) so there will be a complete LC circuit.

Use your scope or high-impedance headphones to check for a tone. If it works, use your scope or VTVM to measure the output voltage at both output jacks as it may vary between units. Don't try to use a VOM on the low-level output. It will load it down to almost nothing. Check for proper operation of the level control and the on-off switch. If you get past all that, you are in business.

The first time I tried mine it didn't work and I designed it! Here are the most likely troubles to look for:

1) Transistor inserted incorrectly in the socket, or you have the wrong pin configuration to the circuit.

2) Weak or dead battery. Check yours under load with meter.

3) Wiring error. Recheck schematic.

4) Coil doesn't make connection with rest of circuit. Unsolder and clean again. Ohmmeter might help here.

The signal should be at the gate of the FET. Lifting one lead of C2 will isolate the output circuit. If there is still no signal at the gate, then the trouble is in the oscillator circuit itself.

Performance

I checked the performance of mine with my usual assortment of ancient and out-of-tolerance test gear and got the following.

The output voltage varies only slightly over the supply-voltage range of 9 to 20 volts. This is a fringe benefit of R1. It holds the output voltage constant over a wide range of supply voltages.

The output drops off slightly with a supply voltage between 9 and 5 volts. At the design center of 9 to 12 volts, the drain current is about 2.2 mA.

The output voltage at the HI output jack (J1) is 15 volts peak-to-peak on the scope. At the LO jack (J2), it is 1.5 volts p-p. Pretty good for a rough and ready attenuator network.

The calculated rms voltage by formula was not what one meter showed. The VOM indicated 4.2 volts rms. The LO range was loaded down too much by the meter. The output across the "output" jack was about +15 dBm—enough for many purposes.

The minimum signal voltage available is about 0.01 volt p-p on the scope. The voltage is still controllable below this level, but you are at the extreme end of the range and there is a higher level of hum vs. signal. Some noise will get in from any test setup, but at very low levels, noise and crud are a higher percentage of your actual test signal.

Your performance measurements will probably vary from mine because of differences in the unit and test equipment used. The absolute values are not as significant as knowing the relative values as measured by your own equipment. This gives you a way to check the performance against a recorded value.

Always keep records on the operating characteristics of equipment you make when you complete it. Then you will have figures to use for comparison when you need them. It won't be guesswork or vague memory.

Odds and Ends

There are a few little odds and ends to really finish the project properly.

Make a full-size schematic diagram of the circuit showing all parts and values, voltage and current, and the actual output at both jacks (use scope if available). A clear drawing of the parts layout will help if you ever have to work on yours. You may not remember it that well in time. You might even make a copy of this article for your service package.

Put all this in the file of service information you keep for your other gear. You do have one, don't you? Then it will be there when you need it. No guesswork.

This is one of the simpler pieces of test gear to use, but there are a few cautions I would like to stress.

If you have been used to working with transistor equipment, you may not be street-wise to the dangers of working in higher voltage tube circuits. This unit will help troubleshoot tube receivers and audio amplifiers, but make sure you observe all safety precautions for working with high voltage. Tube voltage levels are lethal.

Working with transistor equipment is a lot safer for you, but the oscillator has a husky output that easily can blow many transistor stages. Observe all safety precautions for working with transistor circuits, too.

As a general rule, set the controls of the unit under test as they would be for normal operation. Start with the lowest level signal you have and use the least signal that will do the job. You can damage a transistor stage with too much signal or even a static charge. It would be hard to damage a tube stage with this unit, but too much signal can cause distortion. You could be trying to fix a problem that you are causing while testing.

This unit will do a lot for you, but to use it safely and effectively you have to know what you are doing and why.

A good book or two on troubleshooting and repair will give you lots of ways to get the most out of your test equipment. Make sure your library covers both tube and solid-state gear.

A little hands-on experience working with this unit also will tell you a lot about its capabilities. ■

Maximum Modulation for CB Conversions

Many CB rigs lack the gain for full modulation. This preamp will help.

If you have recently converted a CB for 10-meter operation or if your present ham rig has insufficient mike gain, you may be interested in building this simple microphone preamplifier. The majority of CB rigs in the lower to middle price ranges do not provide adequate mike gain for optimum modulation. Typical modulation levels obtained are from 30 to 60 percent. The addition of a preamplified mike can significantly increase the "talk power" of these rigs; just ask any CBer.

There are several commercially-available preamplified mikes on the market that will provide the added audio gain for a price tag of $25.00 to $50.00. A much cheaper alternative is the single field-effect transistor (FET) circuit shown in Fig. 1. I purchased all components for under $5.00 at a local Radio Shack store.

The circuit can be constructed in a separate mini-cabinet by using mating microphone connectors to match those used by your CB or it can be mounted inside the CB. When mounting within the CB, the additional mike connectors, switch, cabinet, and 9-volt battery are not required. You probably won't have enough room to install the potentiometer (R4) inside the CB, but it can be replaced with two fixed resistors once the proper mike gain adjustment level is established.

To provide similar circuit-operating parameters when installing inside a CB, substitute a 33k-Ohm resistor for R3 and connect it to a +12-volt power point in the CB. Also connect the common ground point of the preamplifier circuit to CB ground. Unsolder the existing microphone lead from the printed circuit board and connect it to the input of the FET circuit. Use a short piece of shielded wire to connect the output of the FET circuit to the printed circuit board and ground the shield to minimize hum pickup.

Adjustment is simply a matter of setting the potentiometer for optimum modulation level. This can be accomplished through the use of a modulation meter connected to the antenna feedline connector of the CB or during an actual QSO. Don't forget that the FCC limits the maximum permissible modulation level at 100 percent, so make sure that the gain setting used does not cause audio distortion or splatter.

When you have established the optimum level setting, the potentiometer can be replaced by two fixed resistors connected as a series voltage divider. To determine the proper resistor values, measure the resistance between the center lug of the potentiometer and each outside lug. Obtain two resistors having the same approximate values, connect them in series, and substitute these in place of the potentiometer. Connect the mike lead to the junction between the two resistors. Check that the resistors are installed in the circuit so that they have the same relationship as the measured resistance values on the potentiometer.

The circuit can be constructed on any suitable piece of insulating material. I used a piece of cardboard measuring about 1-1/2" by 3" and mounted the components on one half of the area. I then folded and taped the cardboard under to protect against possible shorting of the circuit connections. ■

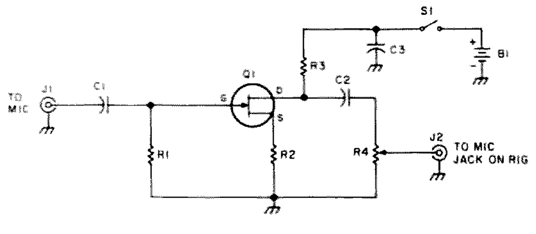

Fig. 1. Mike preamp circuit.

Parts List

B1—9-volt transistor radio battery
S1—SPST switch
Q1—FET, Radio Shack 276-2028
C1—0.01-μF capacitor
C2—0.1-μF mylar™ capacitor
C3—100-μF, 10-V-dc capacitor
R1—2-megohm, ½-Watt resistor
R2—3300-Ohm, ½-Watt resistor
R3—10k-Ohm, ½-Watt resistor
R4—50k-Ohm (or 100k) audio-taper potentiometer
J1,J2—Phone jacks to match equipment

CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

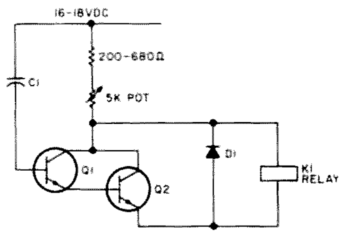

Fig. 1.

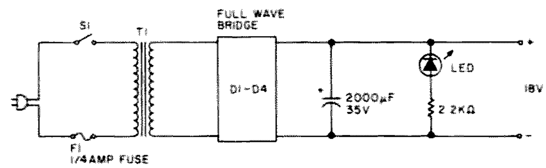

Fig. 2.

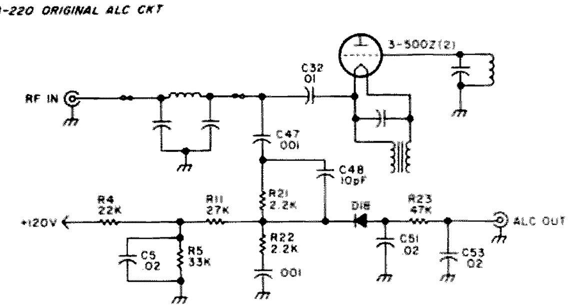
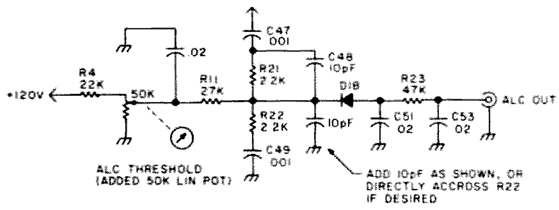
THE KEYLESS KEYER: This circuit can be used to key a transmitter with just a touch. In Fig. 1, Q1 and Q2 are any NPN transistors. C1 can be any disc capacitor. Make sure the leads are long enough so that you can touch them. When the leads are shorted by your finger, the small signal from your body makes the relay drop from 5 volts to less than one volt. The relay toggles. The SPDT leads of the relay can be used to key a transmitter. No dangerous voltages pass through the capacitor. Diode D1 suppresses any high inductive kickback and thus protects the transistors. Use either two 9-volt batteries in series or build the power supply shown. The LED and 2.2-kilohm resistor serve to indicate when the supply is on and to bleed off any dangerous voltages from the 2000-uF capacitor.—Alan Weinberg KR7D, Tucson AZ.

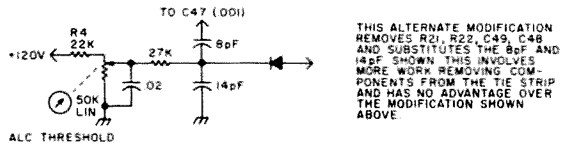
SB-220 ORIGINAL ALC CKT



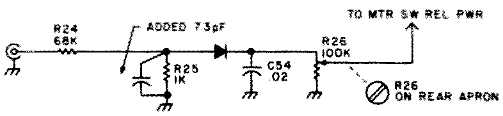
ALC THRESHOLD MOD



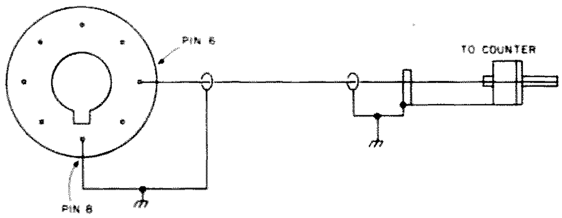
ALTERNATE MOD



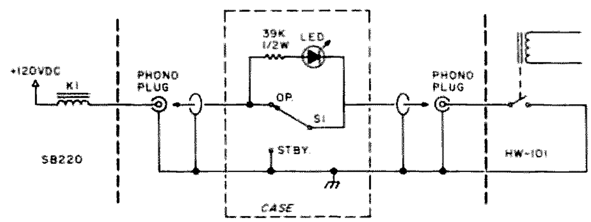
RELATIVE POWER METER CIRCUIT MOD



ALC MODIFICATION FOR THE HEATH SB-220: The ALC level in the Heath SB-220 is virtually unusable with the Collins 32S-3. This modification will provide an adjustable, stable ALC voltage for the SB-220. Install the ALC control in the front-panel position normally occupied by the Relative Power Sensitivity control. The RPS control is then installed on the left rear chassis apron about 4½ inches inboard from the left side. By adding a small capacitor across the R25, the response is made more uniform with respect to frequency. After modification, set the RPS to a reading of 270-280 measured on the grid milliameter.—E. A. Wingfield W5FD, Little Rock AR.



FREQUENCY ADJUSTMENT FOR THE YAESU FT-101: You can use an ordinary frequency counter to tell if your FT-101 is slightly off frequency. Pin 6 on the rig's accessory plug is connected to the vfo output, while pin 8 is ground. Connect a frequency counter to these two pins and check to see if the radio has the same frequency on transmit and receive. The counter will display the vfo frequency — between 8.7 and 9.2 MHz—not the frequency shown on the main dial. You can correct for any difference between the transmit and receive frequency by adjusting the control marked zero, located under the top cover.—Doc Hall W8ZJQ, Elyria OH.



OPERATE-STANDBY SWITCH: This circuit is ideal for a linear amplifier, such as the SB-220, which does not have a standby switch. The circuit requires only three components and a miniature box in which to house them. When S1 is in the OP mode, the 39-kilohm resistor and LED are shorted. Thus, when K1 is energized, the linear is on the air. In the STBY mode, the LED cathode is grounded and energizes. Selection of the resistor is critical: If too low a value, the relay will close in the STBY mode. The exciter can be tuned for maximum power with the antenna connected through the linear's bypass relay. S1 is then switched to OP and the linear can be loaded into the antenna.—F. T. Marcellino W3BYM, Rockville MD.

HAM HELP

I would like to obtain schematics or manuals for the following:

- E. F. Johnson "Ultracom" 30-50-MHz FM transceiver
- Tempo One 80-10-meter transceiver (the black version)
- Unimetrics "Dura-Scan" 30-50-MHz scanner
- Lafayette "Micro" P-50 30-50-MHz tunable FM receiver
- J. C. Penney model 6237A citizens band transceiver
- Kris model XL-70 citizens band transceiver
- International Crystal "Executive" model 1500 citizens band transceiver
- Heath HP-20 power supply

If copies are sent, please specify if they are to be returned or are for me to keep.

Gary B. Trustle WB8SPV
424 Franklin Ave.
Waverly OH 45690

I am looking for:

- Someone who has modified a Heath HD-1410 keyer for use with a Hallicrafters HT-37 transmitter.
- Firms who sell Motorola MV1404 tuning diodes; MAN-1, MAN-64, and MAN-6680 LED displays; and .25% to 1% precision resistors with values of 243k Ω, ¼ W, 11.2k Ω, ¼ W, 2.43k Ω, ¼ W, and 243 Ω, ¼ W. Since the resistors are special items, the firms must be able to conduct business with an individual buying very small quantities.

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION (Required by 39 U S C 3685) 1. Title of publication: 73 *Amateur Radio's Technical Journal*. 2. Date of filing: Oct 1, 1982. 3. Frequency of issue: Monthly. A. No. of issues published annually: 12. B. Annual subscription price: $25.00. 4. Location of known office of publication (Street, City, County, State and ZIP Code) (Not printers): 80 Pine Street, Peterborough, Hillsboro County, N H 03458. 5. Location of the headquarters or general business offices of the publishers (Not printers): 80 Pine Street, Peterborough, Hillsboro County, N H 03458. 6. Names and complete addresses of publisher, editor and managing editor. Publisher (Name and Address): Wayne Green, Peterborough, N H 03458. Editor (Name and Address): Wayne Green, Peterborough, N H 03458. Managing Editor (Name and Address): Jack Burnett, 12 C Granite St., Peterborough, N.H. 03458. 7. Owner (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding 1 percent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a partnership or other unincorporated firm, its name and address, as well as that of each individual must be given. If the publication is published by a nonprofit organization, its name and address must be stated.) Name: 73, Inc., Peterborough, N H 03458. Wayne Green, Peterborough, N H 03458. 8. Known bondholders, mortgagees and other security holders owning or holding 1 percent or more of total amount of bonds, mortgages or other securities (if there are none, so state): Name: none. 9. For completion by nonprofit organizations authorized to mail at special rates (Section 411.3, DMM only). The purpose, function and nonprofit status of this organization and the exempt status for Federal income tax purposes (check one): Not applicable. 10. Extent and nature of circulation. (X) Average No. copies each issue during preceding 12 months. (Y) Actual No. copies of single issue published nearest to filing date. A. Total No. of copies printed (Net Press Run) (X) 69,828 (Y) 66,216. B. Paid circulation: 1. Sales through dealers and carriers, street vendors and counters sales (X) 11,858 (Y) 14,108. 2. Mail subscriptions (X) 47,906 (Y) 45,454. C. Total paid circulation (Sum of 10B1 and 10B2) (X) 59,764 (Y) 59,562. D. Free distribution by mail, carrier or other means, samples, complimentary, and other free copies (X) 446 (Y) 451. E. Total distribution (Sum of C and D) (X) 60,210 (Y) 60,013. F. Copies not distributed: 1. Office use, left over, unaccounted, spoiled after printing (X) 6,355 (Y) 6,203. 2. Returns from news agents (X) 3,263 (Y) 0. G. Total (Sum of E, F1 and 2—should equal net press run shown in A) (X) 69,828 (Y) 66,216. 11. I certify that the statements made by me above are correct and complete. Signature and title of editor, publisher, business manager, or owner: Debra Wetherbee, Business Manager.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

FARIBAULT MN
DEC 4

The annual Handi-Ham Winter Hamfest will be held on Saturday, December 4, 1982, at the Eagles Club, Faribault MN. Registration will start at 9:00 am, followed by a Handi-Ham equipment auction, dinner at noon, and a program. Talk-in on .19/.79. For more information, contact Don Franz W0FIT, 1114 Frank Avenue, Albert Lea MN 56007.

HAZEL PARK MI
DEC 5

The 17th annual Hazel Park Amateur Radio Club Swap and Shop will be held Sunday, Dec. 5, at Hazel Park High School, Hazel Park MI. Hazel Park High School is located on Hughes Street at 9½ Mile Rd., 1 mile east of I-75. Tickets are $1.50 in advance or $2.00 at the door. Tables are $1.00 per foot. Doors open at 8:00 am. Plenty of food and parking will be available. Talk-in on 146.52. For tickets, table reservations, and information, send an SASE to Hazel Park Amateur Radio Club, PO Box 368, Hazel Park MI 48030 or telephone (313) 398-3189.

SOUTH BEND IN
JAN 2

A hamfest swap & shop will be held on Sunday, January 2, 1983, at Century Center, downtown on US 33 One Way North between the St. Joseph Bank building and the river, South Bend IN. Tables are $3.00 each in a carpeted, half-acre room. The Industrial History Museum is in the same building. Four-lane highways lead to the door from all directions. Talk-in on .52/.52, .99/.39, .93/.33, .78/.18, .69/.09, 145.43, and 145.29. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616, or phone (219)-233-5307.

RICHMOND VA
JAN 16

The Richmond Amateur Telecommunications Society will hold Richmond Frostfest '83, the annual winter ham radio and computer show, on Sunday, January 16, 1983, at the state fairgrounds, Richmond VA. General admission is $4.00. All flea-market and commercial exhibit spaces will be indoors in a 30,000-square-foot exhibit building.

PRESERVE
73 MAGAZINE
BINDERS & FILE CASES

Keep your issues of 73 Magazine together, handy and protected in handsome and durable library files or binders. Both styles bound in red leatherette with the magazine logo stamped in gold.

Files: Each file holds 12 issues, spines visible for easy reference. $5.95 each, 3 for $17.00, 6 for $30.00

Binders: Each binder holds 12 issues and opens flat for easy reading. $7.50 each, 3 for $21.75, 6 for $42.00

(Postage paid in USA. Foreign orders include $2.50 per item)

Please state years: 1977 to 1983

CONTACT-80...

An ultra sophisticated yet simple to operate RTTY System for the demanding operator at an affordable price.

Features:
- Disk I/O; SAVE, LOAD, KILL & DIR...
- TRI-SPLIT screen, user defined...
- 10 CANNED MESSAGES
- DYNAMIC BUFFER ALLOCATION...
- Live HARDCOPY for parallel printers...
- Keyboard CONTROL of STATION...
- AUTO-ID; RTTY, CW (selectable ON/OFF)...
- CLOCKED OUTPUT rate...
- All BAUDOT speeds plus ASCII (110)...
- NAME, DATE, TIME from computer...
- On screen BIT PATTERN SCOPE...

Requires TRS-80, MOD-III with your CALL SIGN plus TU with 60ma loop

DISK I/O; VERSION $279.00
CASSETTE I/O; VERSION $229.00

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

For the past few days, I have been reading a book that has struck a responsive chord within me. Detailing some of the goings on behind the scenes of my favorite radio show, National Public Radio's "All Things Considered," the book describes how the show starts with the rudimentary outline first laid out in a morning conference, goes through edits and revisions, and then bursts upon the public at 5:00 pm sounding fresh and spontaneous.

The reason for the empathy I feel is the way RTTY Loop falls together each month. For the December issue, for example, I usually try to take a look at items which could be given as gifts to the ham involved in RTTY or computers. "'tis the season," and all that. Several rough outlines are penciled in over the months until now, when I try to assemble an exciting column.

Well, yes, Maryland (Virginia is a bit to my south), there is a Serendipity. For just as I was casting around, looking for something novel or unique, what comes in the mail but a packet from Tom Harrington of Universal Electronics, Inc.

Tom, you may recall, is the gentleman who produced the book *World Press Service Frequencies*, a tome reviewed in RTTY Loop back in August, 1981. For those who came in late, I shall explain. This publication, now in its third edition, covers the full specs on over 65 stations transmitting press information worldwide in English. Also covered is information on antennas, terminal units, and the like. Well, Tom has a few more goodies up his sleeve. A giant *List of Worldwide Radioteletype Stations in Frequency Order* contains 2198 frequencies of stations logged this year. The frequency, callsign, name of station, ITU country symbol, times of reception, and details are included. Over eighty press and news agencies are listed, along with weather, military, and other services using RTTY.

Not to stop there, Tom has another rather unusual offering. Did you know that there is a five-level code for Arabic, Cyrillic, Hebrew, Greek, and Korean—not to mention a six-level Japanese code? If we throw in Hebrew, Arabic, Cyrillic, Greek, and Japanese Morse codes and then top it all with over 500 identified Arabic words and station names in RTTY, would you be interested? Well, Tom's new work, *List of Special RTTY and CW Alphabets and Codes*, has all this, plus quite a bit more. Write to Tom at Universal Electronics, Inc., 1280 Aida Drive, Dept. L, Reynoldsburg OH 43068. Use order code "R" for the *Worldwide Stations* list, $12; order "P" for the *Press Service* list, $8; and "X" for the *RTTY and CW Code* booklet, $8. Be sure to mention RTTY Loop in the order, too, OK?

Before we leave Universal Electronics, and while we are on the subject of gifts, I think I have something for the high-powered RTTY types among you. Their Universal M-600 RTTY code receiver may be the ultimate demodulator on the market. This unit decodes signals using bit inversion, TOR, SITOR, and nonstandard shifts. Weather as well as standard format is supported with all speeds of ASCII, Morse, and Murray. Output is both standard video as well as ASCII or Murray printers, complete with a printer buffer of 2K. This brief description only summarizes the material I have in hand. I am sure that Universal would love to send you the full details if you drop them a note at the above address. At $799.95, this is quite a package.

If that's too much money for you, but you are looking for an object in the "sizable but not ridiculous" category, have you considered one of the new small microcomputers? For under $300, you can buy an Atari 400 (which has some of the finest graphics I have ever seen and can be expanded to a full system including disk), the TI99/4 (sold in many retail outlets), a Radio Shack Color Computer, or (pushing under the $100 mark), the Sinclair ZX-81, now marketed by Timex and widely discounted. These and other small computers can serve either as a first system or, as my Atari does, as an intriguing second computer for someone already afflicted with the computer bug.

Computers aside, and I will admit that it is becoming harder these days to put them there, there are quite a few products around that appeal to the RTTY buff. I don't know about your wife, but mine enjoys window-shopping during the holiday sale season. How do you window shop in a magazine? You look at the ads! Let's see what is available, right here in the pages of *73*. I must point out that information I have on some of these items is from literature or the advertisements themselves. If you want more details, write to the company, not to me. By the way, I recognize that many products covering a wide range are of interest to the amateur involved in RTTY, but let's look only at specific RTTY items. If you will follow me around the next corner...

I see that RCA is selling off old, used ASR-33 teleprinters. This is a usable terminal for ASCII circuits and would make a reasonable first start for the amateur interested in getting onto ASCII RTTY. We have covered the hookup of the ASR-33 in past RTTY Loops, and many hams have them on the air. Supporting uppercase ASCII only, these 110-baud machines include punched paper tape facilities. At $300, the price may be above what you would pay at a hamfest, but I presume the units are checked out and working. If you are interested, contact J. H. Bell at the RCA Service Company, Bldg. 204-2, Route 38, Cherry Hill NJ 08358.

Going from the earliest to one of the latest, Kantronics offers their "The Interface." For about $190, this box, plus software available separately, will put many popular microcomputers onto RTTY. Software for the Apple II computer is supplied on a diskette for about $30. Program boards, presumably containing ROMs, are available for the Atari 400/800 or VIC-20 for $50, or for the TRS-80C Color Computer for $60. Drop a line to Kantronics at 1202 E. 23rd Street, Lawrence KS 66044, for details.

Producing a fine stand-alone terminal, our old friend Microlog, located at 18713 Mooney Drive, Gaithersburg MD 20879 (just north of Washington DC), is still turning out their 6800-based systems. The ATR-6800, reviewed in this column some time back, is an expandable system which can be turned into a general purpose computer. Their newer ACT-1 (not to be confused with a simple computer terminal of the same name available a few years ago) is a dedicated RTTY/CW/SSTV computer. Both use the Motorola 6800 CPU, of which you all know I am quite fond, and appear to be very well engineered. The ACT-1 is a shade under $1000; I don't have a recent price on the ATR 6800. I'm sure the guys at Microlog would be happy to fill you in.

Another way to get onto computerized RTTY is with a package offered by Tufts Electronics, 61 Lowell Road, Hudson NH 03051. The experts up there will sell you the Kantronics interface detailed above, with a VIC-20 computer, cables, speaker, and instructions for the package price of $499, as of this writing. Sounds like it might be worth a peek.

Another advertised system is the MFJ Super Keyboard. This box operates on CW, Murray, ASCII, and as a memory keyer and Morse practice machine. Two versions are available. The MFJ-494 features a 50-character buffer, 30-character memory, and automatic messages, and sells for about $280. For another $60, the MFJ-496 increases the buffer and message memory to 256 characters each and adds serial numbering and a repeat message function. Options of AFSK keying, loop keying, and clock module are also available. Drop MFJ Enterprises, Inc., a letter at Box 494, Mississippi State MS 39762, if you would like further information.

We can't forget our old friends iRL at 700 Taylor Road, Columbus OH 43230. Their two converters, the FSK-1000 and FSK-500 (reviewed in this column in the past), remain excellent products. They also tell me that they can interface their terminal units to many popular computer systems. Just ask them a question—they say they have the answer.

A common question in the mail has been whether there is an adapter made just for the TRS-80C Color Computer for RTTY. Well, Ridge Systems Co., Inc., is advertising their 4511 RTTY Interface. Selling for about $170, this ROM board supports Murray and ASCII, a split screen, and messages stored to cassette tape. Drop them a note at PO Box 772, Acton MA 01720, for more information.

Xitek, one of the first companies out with a single-board terminal, is still featuring their SCT-100 ASCII/Murray terminal. Listing at $229, it may be of interest to some of you. Their mailing address is PO Box 2952, Garland TX 75041.

Speaking of originals, Macrotronics, Inc., 1125 N. Golden State Blvd., Turlock CA 95380, was one of the first with interfacing to microcomputers. Their "TERMINALL" is a hardware/software system for the Apple II or TRS-80 (Model I or III) that combines terminal unit, computer interface, and bells and whistles into one neat package. For about $500, this is quite a system, supporting ASCII, Murray, or Morse.

Another computer interface, the ROM-116, is available from Crown MicroProducts, 606 State Street, PO Box 892-R, Marysville WA 98270. This package requires an external terminal unit and includes facilities to save text to disk along with other features similar to other systems. Write Crown for a brochure and pricing details.

The TRS-80 remains the most often supported computer for the RTTY interface, with another one offered by Commtek. Their Contact-80 is available for Model III disk or tape systems, selling for $279 or $229, respectively. With split screens, canned messages, date and time, and identifiers from the computer, this looks like a versatile package. Write them at 4493 Orleans Drive, Dunwoody GA 30338, if you are interested.

Another item we will look at in the window-shopping tour is a window in itself. AEA's MBA-RC reader/code converter. This decodes Morse, Murray, or ASCII and displays the data on a 32-character internal display. Not only that, but it can convert between codes, so that an old Murray machine could speak ASCII or Morse on the air. Looks quite interesting, and full details are available from the manufacturer, Advanced Electronic Applications, Inc., PO Box C-2160, Lynnwood WA 98036.

Last, but not least—by any means—is old standby Hal Communications, whose name is almost synonymous with RTTY. You have a complete choice of station accessories and options... enough to build a complete RTTY system or any part of it. For example, the HAL DS3100ASR and ST6000, when combined with the MS03100 Message Storage Option and a hard-copy printer, give you a top-notch station. If you're not prepared at this time to spend all your money on a complete layout, what about the RTTY tuning scope? HAL's RS2100 gives you an accurate display of the signal amplitude and phase of the received signal and a flock of other internal goodies. If you're a travelin' man, you'd like the HAL CWR-6850 Telereader... the smallest RTTY and CW terminal available, according to their specs, and complete with CRT display screen. Communicate with Hal Communications at PO Box 365, Urbana IL 61801.

You know, I often say to mention both *73* and RTTY Loop when you write an advertiser for information or to order something. Let me tell you why. This is not just to toot our own horns. Advertisers spend thousands of dollars putting their name and product before you in various media. They want to know which ones work, and where you hear of them, so that they can better direct future campaigns. The better directed the ads, the less "wasted" money, and the more that can go into better products for you and me. So, you see, telling them that you "saw it in *73*'s RTTY Loop column" is a wise move.

Still stumped for a gift? How about the one that comes a dozen times a year? Less than twenty bucks will get you a one-year subscription to *73*, the magazine that brings the active ham so much more of what you read magazines for. Besides, you wouldn't want to miss the next installment of RTTY Loop, would you?

HAM HELP

I am a wheelchair-bound amateur in need of equipment capable of working the MARS two- and six-meter bands. Please telephone me at (417)-561-4685 or write me.

Edward L. Maranville KA9COJ/AAT7GX
PO Box 512
Rockaway Beach MO 65740

I need a schematic and manual for a Hallicrafters CRX-2 (152-174 MHz) receiver. Any information will be sincerely appreciated. I will pay all costs involved, but please advise me of same first.

HAM GEOGRAPHY

I'm always amazed at the average ham's grasp of geography. As if it weren't enough that most of us are already experts on electronic theory, radio propagation, and telegraphy, we can also claim a knowledge of virtually every square inch of this tired old planet's surface. Who else but a ham is intimately acquainted with such places as East and West Kiribati, Bajo Nuevo, Bouvet, and Chagos? When Great Britain and Argentina began fighting over a forsaken bit of territory known as the Falkland Islands, most of the world ran for an atlas. For hams, VP8-land was an old friend.

This month, Fun! tackles the field of ham geography. Think you know it all? Read on.

ELEMENT 1—CROSSWORD PUZZLE

(Illustration 1)

Across

1) G-land (2 words)
7) From
8) Eastern European land
11) Western state (abbr.)
12) New England state (abbr.)
13) Austria prefix
14) African country
16) To borrow
17) Agency involved in extreme DX (abbr.)
18) Arab country
21) Xmas in France
22) Type of power measurement (abbr.)
24) China (abbr.)
25) 49th state (abbr.)
26) This column
27) Vermont flow product
28) Ø-land state (abbr.)
29) Green Mountain State (abbr.)
31) Soviet prefix
33) Midwest state (2 words)

Down

1) DL-land
2) Southern state (abbr.)
3) African country (abbr.)
4) Far East country (abbr.)
5) A ham radio commercial (abbr.)
6) Belonging to a group of northern states (2 words)
9) Face or type of cup
10) EP-land
13) Peru prefix
15) 6 down district number
19) EI-land
20) US York and Orleans
23) ___ ___ New Guinea
26) ___ ___ Lauderdale
29) India prefix
30) Chad prefix
32) Australia prefix

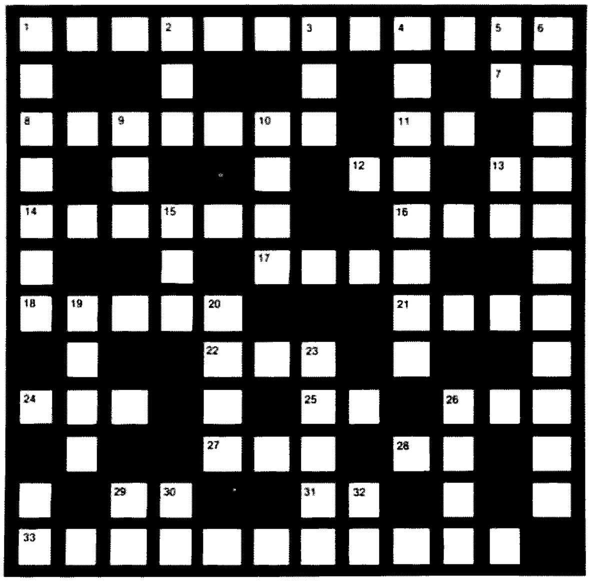

Illustration 1.

ELEMENT 2—MATCHING

Sure, you know all sorts of rare countries by prefix. But do you know their capital cities? Master this subject, and surprise your friend in Paraguay by asking him how things are doing in downtown Asuncion.

Column A	Column B
1) Malta	A) Bogota
2) Bulgaria	B) Reykjavik
3) Romania	C) Manila
4) Nepal	D) Tripoli
5) Maldives	E) Nicosia
6) Bhutan	F) Rangoon
7) Burma	G) Caracas
8) Philippines	H) Katmandu

ELEMENT 3—TRUE-FALSE

	True	False
1) In 1977, the president of the Comoros (D6) had every dog in his capital city of Moroni killed.	______	______
2) North Yemen (4W) used to be known as Aden.	______	______
3) The movie *The King and I* is banned in Thailand (HS).	______	______
4) In Tanzania (5H), wearing a wig is punishable by flogging.	______	______
5) When visiting Nepal (9N), one can stop in government-approved hashish stores.	______	______
6) Timbuktu is located in Mali (TZ).	______	______
7) Half of the population of Kenya (5Z), is less than 16 years old.	______	______
8) Paraguay (ZP) is the only country with two faces to its flag.	______	______
9) In South Africa (ZS), only whites may hold ham tickets.	______	______
10) Dueling is legal in Uruguay (CX).	______	______

ELEMENT 4—MAZE

(Illustration 2)

You know, ham radio is a lot like a maze. Thousands of frequencies, dozens of modes, hundreds of antenna types—it can all get very confusing. Here's a much simpler maze. All it requires is a pencil and some time. No money or physical effort is needed. Thanks go to my Radio Shack TRS-80 Model II for creating it.

THE ANSWERS

Element 1: See Illustration 1A.

Element 2: 1-R, 2-M, 3-U, 4-H, 5-Y, 6-V, 7-F, 8-C, 9-P, 10-X, 11-T, 12-S, 13-J, 14-D, 15-Q, 16-K, 17-G, 18-A, 19-E, 20-W, 21-B, 22-I, 23-L, 24-N, 25-O.

Element 3:
1—False At his witch doctor's request.
2—False No, that was South Yemen.
3—True They believe the film presents a false view of their history. No Yul.
4—True Yul.
5—True Mount Everest ain't the only thing high in Nepal.
6—True Once a great city, it's now a town of about 6,000.
7—True Thanks to a very high mortality rate.
8—True Boon to flag manufacturers.
9—False Not officially, but what's the difference?
10—True Great way to settle frequency disputes.

Element 4: See Illustration 2A.

SCORING

Element 1: Twenty-five points for the completed puzzle or one-half point for each question correctly answered.
Element 2: One point for each correct answer.
Element 3: Two and one-half points for each correct answer.
Element 4: Twenty-five points for the completed puzzle.

How worldly are you?

1-20 points—Hermit
21-40 points—Recluse
41-60 points—Know where your area repeater is located
61-80 points—Armchair traveler
81-100 + points—Man of the World

Illustration 1A.

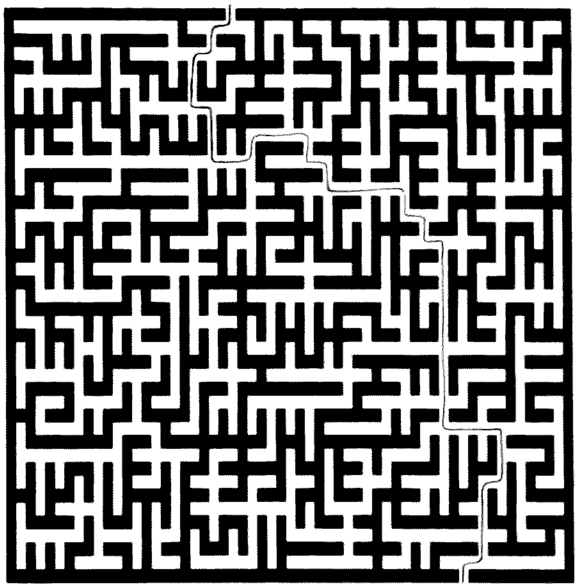

Illustration 2A.

LETTERS

TALK FAST

While reading your response to W6EOT's letter in the September issue it dawned on me just why the "already-known techniques" for high-speed communication are not used in the ham bands.

You say we can communicate at 8,500 words per minute using these techniques. That would be great for traffic handlers (of which W6EOT is one) and maybe contesters if one could figure out how to program the system to be fast enough. One could conceivably work two or three thousand stations per minute!

However, you often expand on how nice good old rag chewing is. I can't understand how you propose to rag chew at 8500 wpm!

Some simple testing of my talking speed netted only 235 wpm. I sure can't talk coherently or even think at 1000 wpm, much less 8500 wpm!

Therefore, to communicate at 8500 wpm, I would have to preprogram some device at my own speed (say 200-400 wpm), contact another station, and punch the proper button to transmit my message at 8500 wpm. I could no doubt say everything on my mind at the time in less than thirty seconds, if I had 4000 words to say.

The other station's reply would then be transmitted to me at 8500 wpm, but I would have several minutes to wait while he programmed reply comments into his "super QRQ box." And, of course, he would have several minutes to wait for my next round of comments.

The fact that actual transmission time is

very small and more stations can use the available spectrum is a nice idea but needs some human engineering, namely, a QRQ to QRS receive converter that would convert the high-speed transmission to normal talking speed with a voice synthesizer, either synced to the other station's voice tones or to a pleasing blonde (for OMs) or tall, dark, and handsome buck (for YLs).

The transmit converter would take a few dozen words spoken into the microphone and blip-transmit them at 8500 wpm, take a few dozen more and blip, and so on.

The receive converter takes the 8500-wpm transmission and begins "talking" to the receive operator at 200 or so wpm (adjustable of course).

And there you have a high-speed system compatible with us relatively slow humans.

Dennis Younker NE6I
Lancaster CA

So what's the difference if your transmitter is on the air, keeping anyone else from using a channel while you mumble inconsequentials at 200 words per minute? Why not have your processor save all that garbage up, put it into a compactor, and dump it at 8500 wpm? Then a bunch of other people could use the same channel. Dunno why we're talking about voice anyway . . . unless all of the code lovers have suddenly died. There are still a few old-time hams around, graduates of early American schools where reading and writing were taught. We could consider opening up classes in our ham clubs on the first two Rs so newcomers could cope with code and printed types of communications.—Wayne.

LETTER ACCELERATION

For some time I have been practicing CW just for the fun of it, as in the HK zone, code is required only for the first-class license.

When getting on the air I find many Novices eager to make the HK contact. They go at my speed when they are calling CQ, but surprise, surprise, once they get to their own callsign, their speed increases by several words per minute, so even if I know that they would immediately answer when they hear the HK coming back to their CQ call, I am not able to call them. Maybe you could write something about this in your magazine.

I usually try to answer CQ calls because when I call CQ with my HK there are just too many stations who come back on my call, even if I sign the HK only once.

I intend to keep you posted on my adventures in CW land.

Rudolf Aumann HK1ESU
Cartagena, Colombia

TOPFSHUTTLER?

My grandmother would say you are a Topfshuttler—a pot stirrer. Isn't that just what an editor is supposed to do? Make people think! You do that well. Obviously, you allow your writers the same freedom.

73's view from Olympus must be a heady one. However, the view is occasionally obscured. Could it be from too much looking down the nose at mortal hams?

A case in point is John Edwards' comment in his column in the July issue, page 123. Commenting on his question, "Do you own a microcomputer?" he stated, "I can't see how a technically-inclined person can be without one." That is editorial nailbuffing from a have to the have-nots and is anything but constructive.

Wayne, please tell the lesser gods at *73* that it ain't 'xactly necessary to have a microcomputer or the latest flamethrower from Japan in order to have fun (and fulfill our responsibilities under Part 97). Yes, *73* should tell us what is new and keep us up to date. But, too often, you promote the idea that the ham should be measured by his equipment when the equipment should be measured by the ham.

Robert F. Solon WD8LKI
Toledo OH

Never let it be said that I interfered with your inalienable right to be totally, thoroughly, ridiculously wrong.—Wayne.

WHAT'S THE FUSS?

You all wanted more teenagers in ham radio? Here I am! I'm 15 years old and just received my Tech ticket. I skipped the Novice test and was really surprised at how simple the FCC exam was. I finished my first year of electronics in high school, which provided all the theory I needed to know, but I had to learn Morse code on my own. I don't know what the big fuss is over learning Morse code. Anyone can do it. Even with the end of the school year approaching and final exams just around the corner, I was able to find time to study code. Everywhere I went I carried a set of phonetic flash cards with me. When I would finish an assignment in class, I would pull out my cards and study a group of letters. I even found time to study during my Spanish final exam! Nobody can use the excuse: "I just don't have the time to study code."

It took me two months before I was ready for the FCC code test. After I took the code test I continued to study Morse code. Within two days I was up to 13 wpm. It kind of made me wish I had held out one more week to take the General code test. I do plan to update to General or Advanced sometime in the near future.

I remember reading a letter in which someone said that the high price of ham gear was keeping kids out of the hobby. I say that is 100% untrue. I agree that prices these days are a little steep, but you do not have to own gear to be a ham. My ham shack consists of a DX-302 receiver and several dipole antennas. My school has a transmitter/receiver combination but we do not have a ham radio club, so I cannot use the equipment. I do plan on starting a club at school but that will take some time. In the meantime, I am asking any ham in the Springfield, Va., area to get in touch with me at 455-1490; I'm dying to get on the air.

I would like to thank the hams who work 3999 kHz at night. I never miss a night listening to this frequency. The more I listened to these fellows, the more I wanted to get my license. Unfortunately, I can't tell them this because I cannot work 75-meter phone. Oh well, this just gives me more incentive to update to Advanced.

Jim Jones N4HQC
Burke VA

STILL BUILDING

Having been involved in ham radio for half a century, I look back at what ham radio was and what it is today.

In the "Good Old Days," the talk during a QSO was largely technical, dealing with home-made projects. Traffic was handled in an era when telephones were considered a luxury. Parts for your favorite projects were always available at "downtown" distributors. A less affluent society made hams more ingenious in their needs.

Today's QSOs are far different! Each new contact allows the ham to list his Japanese-made appliances as if owning a $3,000 layout reflected on his technical ability. But let a transistor or IC go bad, and the appliance is quickly returned to a "repair depot."

The irony is also that, even for those few hams who can handle difficult repairs, manuals for said appliances lack sufficient information or cost fairly large amounts of money!

It is indeed fortunate for current hams that *73 Magazine* is alive and kicking today! For myself, now 65 and retired, the many construction articles have given me many enjoyable evenings. At the same time, local newcomers (age 12-80) likewise were able to discover the "joys of building" via *73*.

Perhaps many readers may disagree with my viewpoints, but I bet the old-timers who remember building a Bearcat receiver or a 47-46-46 push-pull transmitter will agree, the golden years of hamming are past.

Gerald Samkofsky N4ZB
Holiday FL

Oh, guano, Gerald. I started in 1938 and I visited every active ham I could find. They were a bunch of turkeys, just like today. Nothing has changed except your memory. Remember that the first ham contact with Europe was made by a pirate and we never found out who it was. If you've read any 30s ham magazines (or still survive those days) you know that QRM is no better today than it was fifty years ago. Yeah, the old-timers did build, but they didn't know what the hell they were doing and as often as not blew out the filaments by hooking them to the plate voltage. Gerald, I get on 20m and talk with DX that wasn't even imagined 50 years ago and I do it without a lot of trouble. I had a 20-minute contact this morning with a chap in Apia, Western Samoa . . . then a shorter one with a chap in Colombo, Ceylon . . . followed by a nice long chat with HS1ALV. We've never in the history of ham radio had it this good!—Wayne.

DESTINATED

After a few years of operating K1OIQ/R at the summit of Mount Washington, and then this recent summer of traveling about the countryside, I have the following observations and comments to make. This letter was originally a reply to one that I received after criticizing a fellow's operating habits. I would like to give this opinion wider coverage, as it is meant for the entire amateur community.

I apologize only for the way I sometimes come across; tact is one of the things I am still learning. Really, Bill, those of us here are not trying to impose "custom" on anyone's operating habits. Some of it is rather complex—some, kind of stupid I suppose; but I would like very much to get a cheery reply when I call CQ, CQ, rather than some jerk's admonishment: "That's not the way we do it on this repeater." No logic, no conversation, just "that's not the way . . ." Here, at least you get some logic, advice, and conversation as well.

I submit that most hams, like most of the public, are being Madison Aved into an abortion of the language. I am not opposed to such a word as "destinated" (though I hear from a lot who are). I don't know of a shorter, more to the point way of saying, "I'm at to where I'm goin'." The coining of such new words is how our language grows; some day Mr. Webster may even include it in his book. However, I do object to the misuse of language (words and grammar), the sometimes cliquish use of words and phrases, the double question to which one can always answer yes and/or no and still be right, and the long-winded, nonstop monolog method of two-meter operation when, as I think, it should be more like face to face (eyeball, hi hi) or telephone like. Not to mention the editorial we—and the sometimes never ending ID.

Now that I've got this started I shall continue (might even send this in to my friend Wayne Green, hi hi—I might even write a book).

Handel (?) . . . no, I think that's supposed to be handle . . . yes that's better; "handle" is bad enough . . . is for pots . . . is made of wood . . . the vandals stole my handles so I have to use my name (hope you don't mind) . . . Have you been asked for your "personal"? ". . . the personal here is . . ." "What's a personal?" said I in reply; and the new ham apologized for having been a CBer. "No apology expected nor required," I said. "Some of my best friends used to be CBers; a lot of us have taken that same promotion. No ham shack is complete if it doesn't have a working CB radio. But let us try speaking English here, not some silly dialect."

And then there is the editorial we. *We* did this and *We* did that and *We* are going and *We* are using . . . I was listening in one day (needless to say I've got LISTENERS NET LISTENING CERTIFICATE #1) when a friend of mine replied to one of those we-we-we monologs by saying how it was ". . . so wonderful that you and your wife can do everything together . . ." The we didn't even respond. What ever happened to I? Is it taboo or something to say "I did this . . ."?

And the never ending ID. Bad enough again, what with ID required only once every ten minutes, that two hams will ID back and forth after every speech . . .

". . . WWW this is ZXC and back to you before I time this thing out. Ya ZXC this is WWW fine business . . . blah blah and OK on this, that, and the other thing . . . ZXC this is WWW. OK WWW, ZXC right back . . ." and on it goes. But when there are four or five of 'em and each one has to say the calls, in proper turn mind you, they spend more time blowing all the horns than they do in any meaningful conversation.

SO! if one wants to "listen" or "monitor," calling out and announcing same once a day should be sufficient. Also, I feel it should be a "custom" that one who has previously announced that he is "listening" should announce "not listening" when not.

ABC signed on "listening." A minute or so later ZXC announced he was "listening." ABC "listened" again a short time later and before the tail dropped, ZXC "listened" a little louder. Finally, after a pregnant pause, ABC *called* ZXC and the usual ". . . fine business, nice to meet you, hope to see you further on down the log . . ." QSO followed. Now tell me Bill, was that a "customary initiation of QSO" or was that a "power struggle"?

If what one really wants is to QSO, then I respectfully submit that what one should do is call. Call, as in CQ, CQ. Or, if that is too straightforward and meaningful, then at least something like "Hullo radio! . . ."

In this arena I am not concerned with custom; I am not trying to promote any particular way over any other way; I merely want people to say what they mean, be concise, and not be afraid to say "I" once in a while so that when they say "we" you'll *know* there is more than one of them.

However, I'll turn right around and fall back on custom when it comes to badmouthing the shortcomings of the tourists. I know it is the tourist money that "helps keep New Hampshire green." But I also

know what it is to be a tourist . . . and hear all the speed demons from Massachusetts griping about being behind a slow-moving farmer.

I censor neither what nor who gets talked about on this repeater. I encourage and even incite lively debate. It seems to me that most of the folk on the receiving end of these barbs are so serious and uptight about their inanities that they fail to see the humor in a serious debate.

If only I could run the repeater on all this hot air.

Al Oxton K1OIQ
Mount Washington NH

Feel better now?—Wayne.

THE $1.98 LICENSE

I just finished reading the code vs. no-code gangfight letters in the October issue. Frankly, I felt like throwing up. Such lack of imagination; such lack of perception. What we need is negotiation. You know what negotiation is: that's where them what have agree to give all or part of it away in return for return of a hostage, or not getting their heads busted, etc.

In the spirit of negotiation, let me suggest that no one has tried to unite all the factions of this argument by proposing an amateur radio licensing program with something for everyone. Let me then address it from that standpoint.

First, we need to set a goal; hell, anyone familiar with success can tell you that you must establish a goal. The goal must be reasonable—one you can expect to be able to fulfill by a certain time.

Amateur radio's goal then should be to find the method by which everyone will be licensed within 3 years . . . Change that: everyone who wants to be a ham; we don't want anyone bitching about how we forced him or her to become a ham.

I hear it already: someone saying, "Where would we put them all?" We have literally millions of amateur radio frequencies which are relatively unused. No one said everybody had to be on 20 meters.

The reason for not proposing to include any life forms in other galaxies is twofold. First, it is unreasonable, and the goal must be kept reasonable to be feasible. Second, although the life form known as "slime" must be integrated into amateur radio if we are to meet our goal (a belief in the "inherent goodness of man" being implicit), we do not know whether or not we would want to share our frequencies with other life forms. Between slime and upright man, we should be able to bring enough hams into amateur radio to make it worthwhile for manufacturers and others with pecuniary interests, thereby assuring the future of our bands.

It thus being established that our goal should be to make available an amateur radio operator's license to anyone and everyone who desires one within 3 years, let's look at how to accomplish our goal.

First, the US should lead the way and show the rest of the world how it's done. Wayne Green has stated many times that the FCC has stifled the growth of amateur radio here. Anyone familiar with the doldrums which followed the incentive licensing system imposed back in the 60s should require no further proof. Anyone, though, who needs more proof as to whether or not the FCC should administer the amateur radio service, is reminded of the Citizens Band class-D service and the monumental FCC mismanagement there. Clearly, we do not need the FCC, and responsibility for amateur radio management should be moved to the private sector. More recommendations on that later.

The big hang-up seems to be inflexibility by all parties. I would remind you, if you admit you are inflexible, that when it became apparent Johnny could not read, rather than universities going out of business they provided new innovation. Their goal remained unchanged: to pass out the degrees. Only the requirements changed. Rather than being compelled to submit to remedial reading classes, colleges gave credits for music appreciation, penny pitching, ant watching, etc. This innovation, coupled with sports scholarships and the introduction of new specialties in the liberal arts, kept the degrees flowing. It didn't do a damn thing about Johnny's reading difficulty, nor technically staying ahead of the Russians, but the universities remained open.

US hams are accustomed now to the multiple-choice examination style. Our solution lies in going a step further. We should allow the amateur radio aspirant the greatest possible latitude in the entry requirements for our fraternity, within certain reasonable limits necessary to protect the integrity of amateur radio, lest someone succeed in obtaining a license for his dog, etc. There is enough bitching without that. An either-or testing format would allow the aspirant to choose only subjects they feel confident in.

As an example: Code is a requirement for the HF bands, but, as letter writer Roger E. Berube points out in the October *73*, code is our link to nostalgia. Machines can now send and receive code, usually faster and cleaner than humans. If an inability to learn code is the only obstacle keeping out an aspirant, then he should be allowed to demonstrate some other skill in lieu of sending and receiving code by hand. Perhaps he is a skilled typist, or could learn to type easier than he could learn to copy code. If so, he should be allowed to appear for testing with his computer keyboard and digital code readout under his arm. Provided he successfully operates his machinery and has ample reading skills, he should pass the code test without investing in the *73 Magazine* code tapes.

We could also simply fail to honor our commitment to ITU and drop the code requirement, as some countries do, upon demonstration that the aspirant has finely tuned his "money" skills. An aspirant with money should be permitted to substitute money for code skill. This would just be a liberalization of a policy popular in the Third World . . . or perhaps there is some other explanation why many of their phone (or phony) ops clutter up the bands which gentlemen have long reserved for CW only, ending each sentence with "Roger, QSL?" and refer to the CW underneath them as "portadoras" (carriers?). *Alguien nos esta poniendo una portadora* . . . Roger, QSL? (Someone is putting a carrier on us, Roger, QSL?)

The Roger, QSL? kind of operator, when allowed a reciprocal license to operate in the US, is the subject of considerable anguish at the FCC, which threatens to stop third-party traffic for all reciprocal licensees (if not all US hams). Further evidence that the FCC should not be involved in administering amateur radio! Our fraternity should be turned over to the private sector for administration and the second step after the abolishment of code should be to strike out the requirement that amateur radio communications be noncommercial. No other aspect of amateur radio is noncommercial; why shouldn't we allow tow-truck dispatchers to use it and foreign visitors to conduct their financial dealings via amateur radio? Nets could even be set up to allow hams to manage their stock transactions right on ham radio, since eventually our goal is to license everyone on Wall Street as well.

People are basically good; everyone will behave himself or herself. Remember that if they won't, we can just legalize the offense.

Or, perhaps the trouble is not with the code at all, but with the theory, or the rules. We can be flexible here as well. If a person can copy 20 wpm, but can neither read nor write coherently and without moving his lips, he should not be denied access to an amateur radio license so he may participate in our fraternal brotherhood. In lieu of a theory or rules examination, he should be permitted to demonstrate some other skill, or possess money. Such substitute skills should of course be radio-related: wire splicing, tube replacement, etc.

Now the big question about who should replace the FCC in administering amateur radio. If the job were turned over to the ARRL, then *Ham Radio*, *73 Magazine*, and perhaps *CQ* (is there still a *CQ*?) would cry foul. I submit that the federal government should, as an expedient to our reaching our goal in 3 short years, sell the management of amateur radio to the highest bidder in the free enterprise market, to be operated as a concession.

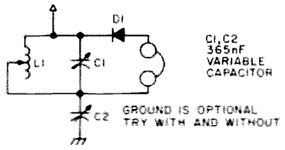
Cereal companies have an inherent edge here, since they have the box-top and $1.98 marketing technique down to a science. Providing an aspirant can demonstrate the ability to properly fill out the coupon, locate the proof of purchase seal on the package, and has the requisite $1.98 or equal value in food stamps, nobody should have any difficulty in becoming a genuine radio amateur, state of the art.

A test frequency has been set aside where this is essentially the licensing technique. If you care to listen, it's 27.185 MHz.

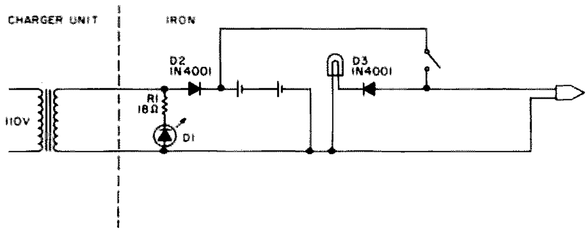
Robert G. Wheaton W5XW
San Antonio TX

Thank you, you've been most helpful. Now, does anyone else have any more gasoline to throw on this here fire?—Wayne

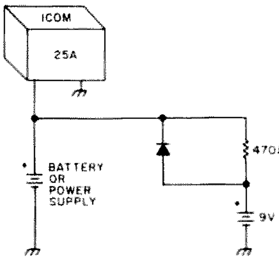
CIRCUITS



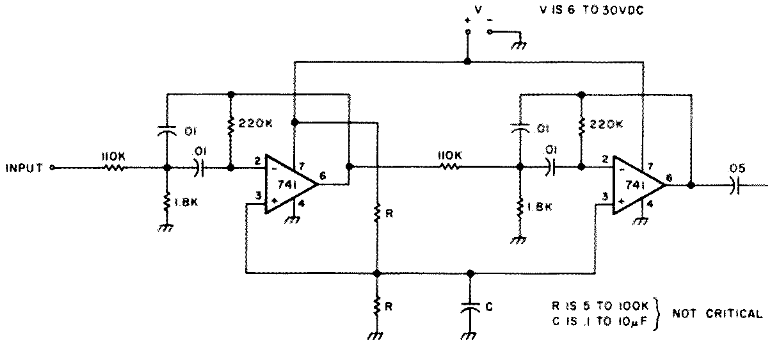
AM BROADCAST RECEIVER: Here is a neat project for a first-time builder. The gimmick is the coil L1. By using an alligator clip at the various taps on the coil, stations are shifted to the lower frequencies on the capacitor. This enables you to separate the stations more easily. D1 is a 1N34A—don't use a cheap diode. C1 and C2 are both 365-pF variable capacitors. A good earth ground is required (the finger-stop on a dial telephone is ideal).—Jim Burtoft N3BQH, Washington PA.



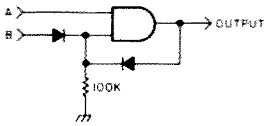
SOLDERING IRON MODIFICATION: To have a better rechargeable soldering iron, remove the diode from the charging unit and install it on the soldering iron. Because the nicads in the iron will now be isolated from the charging pins, it will be impossible to short out. By placing an LED with a current-limiting resistor into the iron, you will get a visual indication every time the battery is charging. Installing the circuit shown here will enable you to charge your battery from either ac or dc. By installing a power diode in the headlamp circuit, the lamp is protected against accidentally burning out when the battery is at full charge.—Richard J. Molby WB7NZG/DA1DB, APO NY.



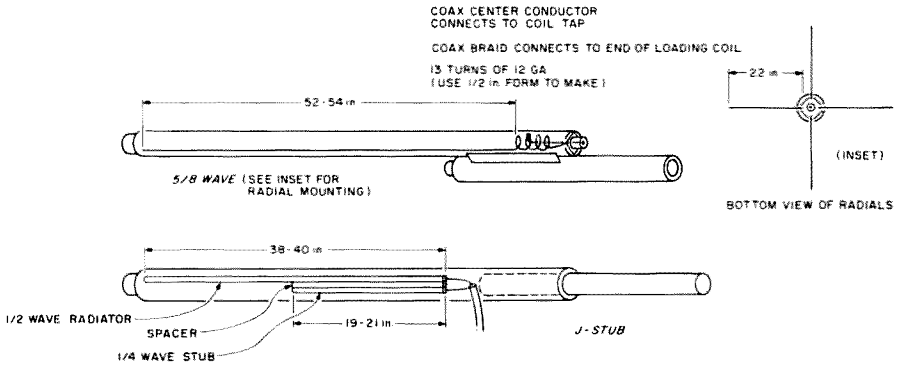
IC-25A BATTERY BACKUP: Here is a simple but effective battery backup for retaining memory when the rig is temporarily removed from the power supply. In tests, the battery retained the memory over eight hours.—Francis J. Piraino WA3KKM, Pocono Summit PA.



TWO-STAGE ACTIVE FILTER: This filter passes an 800-Hz signal. A single section has a bandwidth of about 150 Hz; the two-stage version's bandwidth is approximately 100 Hz. Gain is close to unity at the passband center. The circuit should be added in a low-drive-level section of the audio amplifier if a 12-volt power supply is used.—Penn Clower W1BG, Andover MA.



SIMPLE AND/OR LATCH: This circuit can be used to trip a repeater relay in a timer circuit. For example, if A is high and B is pulsed by a timer, the output will latch high until the input signal ceases. The high output can be used to disable the transmitter. This eliminates the necessity of having a timer which remains high until well after the desired count is reached. A brief pulse is all that is required. The resistor is needed to hold the B input low since the diodes isolate the input. An OR gate could be used in place of the diodes, but the diodes work well. The gate is a CMOS 4081 or a 4011 NOR gate coupled to an inverter at the output.—John Ackermann AG9V, Green Bay WI.



THE PVC PRINCIPLE VHF ANTENNA: Take one 6' and one 9' piece of 12-gauge copper wire and pull each piece until both are slightly longer. This serves to stiffen the copper. Wind the 6' piece 13 turns on a ½-inch form. Leave ½ inch unwound to make a connection. Remove the coil form and cut the "one piece" radiator as shown. Solder one end of a short length of 28-gauge copper wire to the center terminal of an SO-239 and the other to an alligator clip. Attach the clip to the coil about 2 turns from the radiator. Cut the 9' piece into four equal lengths (2¼') and attach them to the SO-239 as shown. Hang the antenna so that you can trim it for vswr adjustment. Vswr is adjusted by 1) coil tap position, 2) spacing of coil turns, 3) radiator length, and 4) length/angle of radials. After vswr is optimum, solder the coil tap in place. The trimmed antenna can be slid into PVC pipe and epoxied into place. To make the J-stub, take three pieces of RG-8 coax, two 19-21 inches and one 38-40 inches. Carefully remove the outer insulation and braid. Lay the three pieces on a flat table and tape them together temporarily. Solder the coax to the antenna, and connect it to the radiator and the braid to the stub. The radiator/stub assembly can be slid into a PVC pipe. Unsolder the coax, thread it through the hole, and solder it back. The end can be capped and coax putty applied.—Jack Sammarco KC2FS, Union NJ.

NEW PRODUCTS

16-DIGIT DTMF DECODER

Palomar Engineers has announced a new low-cost 16-digit decoder, model P-411. The decoder features high-input impedance so it does not load the line, crystal control for long-term stability and operation over a wide temperature range, dual band-pass filters ahead of the detector, and digital logic that makes it almost entirely free of false outputs. The P-411 operates from + 12 volts dc and has a 16-line output as well as BCD code and strobe on 5 lines.

For further information, contact *Palomar Engineers, 1924F W. Mission Road, Escondido CA 92025; (714)-747-3343.*

PORTABLE EARTH STATION

The first completely portable, battery-powered Earth station for receiving satellite transmitted television has been introduced by Gillaspie and Associates, manufacturers of state-of-the-art satellite equipment. The system can be tossed into a station wagon or recreational vehicle and used by campers to watch up to 105 channels of TV. The product also has more serious applications because of its ability to provide visual and audio information and data to remote, communications-poor areas.

The system can provide nine to ten hours of television before the batteries have to be recharged, so it could be used to communicate in civil defense emergencies or natural disasters and in areas susceptible to power outages. The system consists of an 8- or 10-foot metalized-fabric dish antenna that collapses like an umbrella, and a battery-operated satellite receiver complete with a five-inch screen. It can be hooked up to a battery-powered television set if a larger picture is desired.

The portable unit, like the larger home systems, collects microwave beams sent from satellites circling 23,000 miles above. It electronically amplifies less than one Watt of power more than 10,000 times to produce clear, undistorted picture and sound.

Additional information may be obtained through *Diane McNutt, Donald J. Sherman & Associates, 4300 Stevens Creek Boulevard, San Jose CA 95129; (408)-247-7300.* Reader Service number 489.

LOW-COST WIND POWER

Thermax has announced a new wind generator design for small power systems. The TC25WG helius rotor kit was developed as a low-cost battery charger for remote sites and applications, including power for camping, boats, radio operation, RVs, cottages, experimentation, and emergency power. The patented helius design offers several advantages: It responds to winds from any direction and is self-starting. The TC25WG rotor operates at low rpm and avoids overspeed problems common in propeller designs. Virtually no maintenance is required, and the Lexan® vanes resist sun, snow, sleet, and extreme temperatures. Assembly is easy with regular hand tools.

A free information package and further information are available from *Thermax Corporation, One Mill Street, Burlington VT 05401.* Reader Service number 481.

SUPER-RATT SOFTWARE

With the Super-Ratt radioteletype and CW program for the Apple II, you can have your own RTTY RBBS station on line quickly and easily, according to Universal Software Systems. Super-Ratt is the lowest-priced RTTY/CW program which also contains a full radio bulletin board system.

The program will operate in ASCII as well as Baudot at any speed from 40 to 300 baud. CW speeds range from 5 to 100 wpm, with an automatic speed adjust on receive.

The program may be run in either manual or RBBS modes. Extensive use of disk files permits storage of "canned" material for manual operation. In the RBBS mode, the system automatically saves nearly one hundred user messages to the disk. There are thirty-five different commands on the RBBS. They are all simple English words—and quite memorable.

Almost any modern terminal unit or converter, such as IRL, Flesher, Kantronics, HAL, or others can be used with Super-Ratt as well as such devices as the "RADCOM" card by AF6W. The program is not protected against copying. The Basic portion may be listed and modified to suit your tastes. (The registered owner's call is installed in the machine code by the factory.)

A free one-year subscription to the user newsletter, *The Ratt's Nest,* is included in the purchase price of $59.95, which also covers shipping via UPS or first-class mail.

For a complete data sheet or other information, write or call *Universal Software Systems, Inc., 9 Shields Lane, Ridgefield CT 06877; (203)-438-3117.* Reader Service number 488.

The Synchronar 2100 solar watch.

SOLAR WATCH

Riehl Time Corporation has just announced a new technological breakthrough in wristwatches, the Synchronar 2100, powered by the sun and programmed to the year 2100 with no resetting required, even for daylight saving time or leap-year adjustments. Miniature silicon solar cells automatically gather and store energy from the sun, daylight, or even an ordinary lightbulb, and this energy is used to drive a complex integrated circuit. The solar cells also measure the ambient light and adjust the brightness of the readout so that it may be viewed under any lighting conditions ranging from full sunlight to total darkness. Synchronar's system totally eliminates the problem of battery replacements, and even if left in a drawer for months, it will continue to operate.

Synchronar 2100 has dual time zones and is available in either standard or international time modes or a combination of both. It is guaranteed accurate to within plus or minus four seconds per year. An exclusive self-calibration system enables the wearer to adjust the watch to run faster or slower, should environmental extremes require recalibration.

A discrete alarm system, or "polite" alert, is provided which, at a prescribed time, causes the display to flash on and off for a period of one minute. Synchronar 2100 features a patented, totally-sealed construction in which all electronic systems are encapsulated within a transparent Lexan module which can withstand shocks up to 25,000 G and water depths up to 750 feet.

Light enters the top surface of the transparent module and charges the solar cells, and the lighted display shines out through the edge above the band, providing a naturally-positioned side view. Control switches are magnetically operated from outside the watch, meaning that the seal of the module is never broken.

For further information, contact *Riehl Time Corporation, 53 South Jefferson Road, Whippany NJ 07981*. Reader Service number 485.

RADIO RACK

The Guild Radio Rack comes in finished solid ash. No assembly is required. Guild's rack comfortably holds Kenwood's TS830S/VF0230/SP230 or TS820 series, or any similar rigs. Exact measurements are (overall) 16-7/8" W times 14-3/4" H times 14-1/2" D; (top compartments) 7-1/2" W times 6" H, and (bottom compartment) 15-5/8" W times 7" H. It is also fully vented.

For more information, contact *Guild Radio Rack, 225 West Grand St., Elizabeth NJ 07202; (201)-351-3002*. Reader Service number 487.

TRIBAND BEAM

TET Antenna Systems has announced that their top-of-the-line HB35T triband beam is now available. This is a 5-element dual-drive antenna for 20, 15, and 10 meters. With the dual drive concept, both the radiator and the reflector are driven with a phase difference that provides extra gain and improved front-to-back ratio.

The beam has only one pair of traps per element for simplicity and reliability. The trap capacitors are coaxial rods mounted inside the elements to give low losses and weatherproof operation.

The HB35T has a 25' boom, weighs 50 lbs., and provides excellent gain for DX work.

For further information, contact *TET Antenna Systems, 1924E W Mission Road, Escondido CA 92025*. Reader Service number 480.

HAMTRONICS FM REPEATER

Hamtronics, Inc., has announced the availability of the REP-100 line of complete repeater packages, including all the hardware and controls.

The REP-100 is constructed on a 7-inch rack panel, with an uncluttered control arrangement. Electrical features include excellent sensitivity (0.15 uV at VHF and 0.2 uV on UHF), both 8-pole crystal filter and ceramic filter for ± 12 kHz at − 100 dB, afc and hysteresis squelch to lock onto drifting or fading signals, a clean, easy-to-tune transmitter, and up to 20 Watts output. A proportional-controlled crystal oven option provides 2 ppm frequency stability down as low as − 30° C (− 22° F), if needed.

The REP-100 repeater is available for the 6m, 2m, 220-MHz, and 440-MHz bands and adjacent frequencies. It is available also in configurations for remote linking and crossbanding, including 10 meters. The 2m and 220-MHz models employ a 3-section helical resonator in the receiver front end. The UHF version uses 6 tuned lines in the receiver. (That is important if you share a site with other transmitters.)

A complete catalog on the REP-100 repeater, and other information, is available from *Hamtronics, Inc., 65-F Moul Rd., Hilton NY 14468-9535; (716)-392-9430*. (For overseas mailing, please enclose $1.00 or 4 IRCs.) Reader Service number 491.

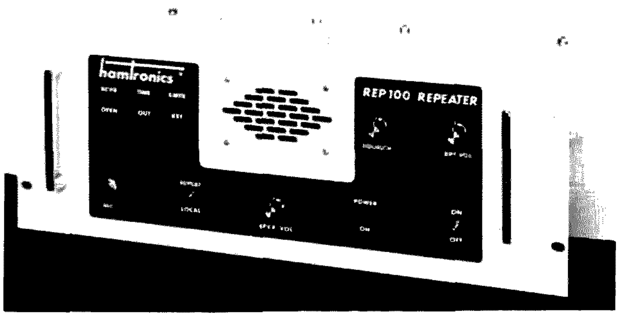
The Guild Radio Rack.

SATELLITE TV ANTENNA KIT

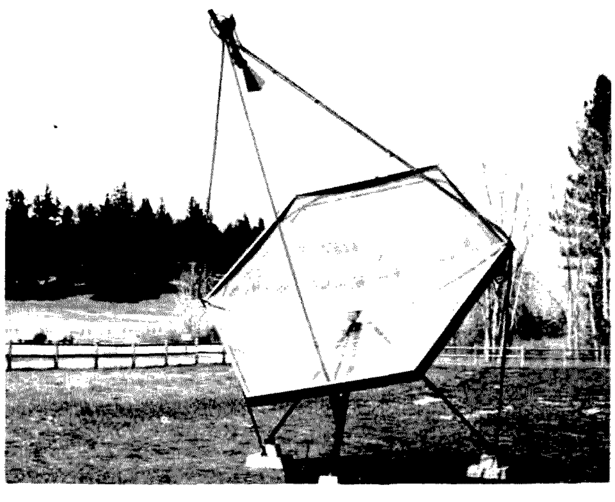
Ghost Fighters, television antenna specialists, has announced the Space Cowboy P-600 series of parabolic antenna kits.

The Space Cowboy P-610 is a 10-foot hexagonal parabolic microwave antenna specifically designed to receive signals from all the domestic satellites, with over 60 channels of video and audio programming to choose from. It tracks the satellite orbit belt on a polar mount and changes from satellite to satellite in seconds. This kit is for the home-video enthusiast who wants to save money and have the satisfaction of building.

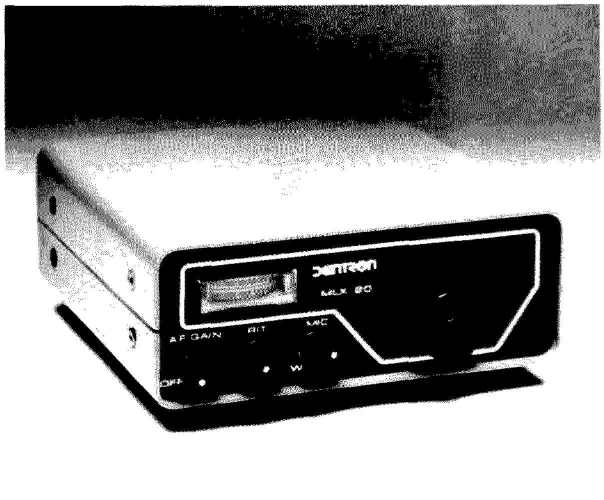
The P-610 model, compared with most 10-foot fiberglass dishes, has a surface-intercept area 10% larger and a longer-than-average focal length. Surface accuracy is proofed-on-site and fully tunable over the entire surface on a point-by-point basis (patent pending) for maximum gain and good picture quality. The surface is heavy-duty galvanized steel screen. The P-610 is a true parabolic reflector with at-



The Hamtronics REP-100 repeater.



The Space Cowboy by Ghost Fighters.



DenTron's MLX Mini transceiver.

tached feedhorn assembly and adjustable polar mount for easy selection of satellites.

The kit comes complete with all materials pre-cut and ready for assembly. Some portions of the assembly will require two persons. Assembly and installation of the antenna can be accomplished by the average homeowner in a weekend or two. The polar mount is set on three concrete footings requiring 4 to 6 bags of pre-mix concrete.

Other models in the P-600 series include the P-613 and P-616 (13- and 16-foot antennas respectively).

For further information, contact *Ghost Fighters, TV Antenna Specialists, Route 2, Box 136-B, Stevensville MT 59870; (406)-642-3405*. Reader Service number 479.

NEW MICRO SIDEBAND TRANSCEIVER

DenTron Radio Company has announced production of its new mini-sized, monoband transceiver. Titled the MLX Mini, it operates at 25-W PEP and 20-W CW with an LED frequency readout of ± 100 Hz accuracy. Available in models from 160-6 meters, the MLX Mini has selectivity of 2.1 Hz with sensitivity better than .35 uV for 10-dB signal-to-noise ratio. Receiver design is the single-conversion superheterodyne type with total power requirements of 12-14 V dc.

For more information contact *Tim Neill, Technical Sales Representative, DenTron Radio Company, Inc., 1605 Commerce Drive, Stow OH 44224; (216)-688-4973*. Reader Service number 482.

GLOBAL'S DIGITAL PULSER KIT

The DPK-1, a new digital pulser kit designed for use as a pulse injector in stimulus/response testing of digital circuitry, has been introduced by Global Specialties Corporation.

This pulse generator is a portable test instrument featuring multi-logic-family compatibility; it operates on both TTL and CMOS circuits. Its pulse width is 1.5 seconds ± 30% for TTL and 5-V CMOS and 3.0 seconds ± 30% for 15-V CMOS.

One touch of the pulse button and the DPK-1 attempts to inject a positive pulse, then a negative pulse. One of these pulses is ignored, depending on the logic state the DPK-1 output is biased at (determined from node under test). Keep the pulse button depressed and after one second the DPK-1 delivers a continuous pulse train of positive and negative pulses at a rate of 150 pulses per second. In the same manner as the single-shot event, one of these pulses will be ignored, leaving a positive- or negative-going pulse train at a 75-pulse-per-second rate.

An LED indicator flashes once to confirm single-pulse output and remains on for continuous pulse train confirmation.

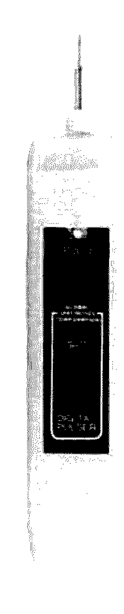
Pulse voltage level is determined by the current requirements of the node under test. The DPK-1 output pulses are capable of sinking or sourcing up to 100 mA, which is sufficient drive to permit forcing most nodes to an opposite state without desoldering.

This digital-pulse generator offers short-circuit protection. High impedance output (minimum, 20-megohm) when not pulsing allows the DPK-1 to pulse into a short circuit continuously without damage.

The DPK-1 is circuit-powered at 5-18 V dc from Vcc of the circuit under test. A power cable, wired directly into the unit, terminates in two color-coded vinyl-jacketed alligator clips.

The DPK-1 digital pulser comes as a complete kit, including all parts, solder, wire, PCB, etc., and a comprehensive construction and operating manual. Kit construction and testing can usually be completed in one to three hours. Its dimensions are 5.8" × 1.0" × 0.7", and it weighs 3 oz.

For further information, contact *Global Specialties Corporation, 70 Fulton Terrace, PO Box 1942, New Haven CT 06509; (203)-624-3103*.



Global's digital pulser kit

AIDS FOR THE BLIND AMATEUR

Although many textbooks have been translated into braille and onto recorded media, blind hams, technicians, and scientists are faced with the continual frustration of obtaining current and supplemental materials.

The Rehabilitation Engineering Center publishes a newsletter quarterly in braille, large print, and recorded form which will serve as a guide to the current technology as applied to the needs of the blind and persons with impaired vision. The newsletter, called *Technical File*, facilitates the pursuit of electronics interests among technically-oriented, visually-impaired persons by serving as a reference source, a teaching tool, and a hands-on guide for construction projects through lists of materials already transcribed, catalog abstracts, data on integrated circuits, manufacturers' applications notes, and construction details, to list just a few of the contents.

General interest, do-it-yourself descriptions of such processes as soldering, project layout on circuit boards, and the use of power tools focus directly on techniques used by the blind. The articles in *Technical File* are submitted by readers, training-facility personnel, and other interested professionals and non-professionals.

In the Winter, 1982, issue, for example, "Soldering, Part IV," "Singing Chips," "A Tactile Read-Out for Digital Instruments," "Earphones for the Blind Traveler," and "Vocational Aids Catalog" were among the features. Bill Gerrey's "Editor's Corner" and "Editor's Crystal Ball" are always popular.

For your subscription to the Braille Edition ($12 per year), the Large Print Edition ($12 per year), or the Talking Book Edition ($6 per year for half-track cassette, 15/16 IPS) contact *Bill Gerrey, Editor, Smith Kettlewell Eye Research Foundation, 2232 Webster Street, San Francisco CA 94115*. Reader Service number 476.

PROHAM'S FASTRAK ELECTRONIC KITS

Proham Electronics, Inc., has just introduced a new line of electronic kits dubbed the Fastrak™ series, wherein each kit is a functional building block that can be assembled in less than one evening. Fastrak modules are for the novice and experienced home-brewer alike, providing not only versatility but complete documentation as well. Each module is built on a commercial-grade printed circuit board that conforms to the HAM (Hardware Application Module) Standard described in the May, 1982, issue of *QEX* magazine, and is uniform in size. Exact board dimensions are governed by the amount of space required to accomplish the intended electronic function, but connector arrangements, bus wiring, and PC-board form factor are uniform and constant for simplicity of assembly and interconnection between units.

Fastrak modules feature a top-down system design, making it easy to configure and assemble complete receivers, transmitters, controllers, and instruments from standard "family" members. Ten Fastrak modules are available, with another ten coming within six months. Functions performed range from basic voltage-regulator and audio-amplifier modules to a 2-chip DTMF decoder and a 1-chip TV.

Fastrak kits come with complete documentation and use readily available components. For more information, write *Proham Electronics, Inc., 34620 Lakeland Boulevard, Eastlake OH 44094*.

ICOM IC-45A SYNTHESIZED UHF MOBILE

Icom has announced availability of the IC-45A, providing FM mobile coverage of 440-450 MHz. Major features are its small size (2" H × 5½" W × 7" D), easy-to-read LEDs, 5 memories, priority channel, band and memory scan with automatic resume, memory backup provisions, 1-MHz up-button for quick QSY, and variable duplex offsets. The touchtone™ microphone is included.

For more information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155*.

The Icom IC-45A synthesized UHF mobile

MOBILE ANTENNAS

Valor Enterprises, Inc., introduced a new series of mobile high-frequency antennas at the Chicago CES Show last June. These HF mobile antennas for the professional and amateur operator are approximately 8 feet in length, and are of a heavy-duty, slim line construction designed for HF amateur bands on 75, 40, 20, 15, and 10 meters. Heavy-gauge copper wire wound on ½" fiberglass with nickel-chrome brass fittings, and 17-7 taper ground stainless-steel

whips ensure dependable mobile operation. The 4' stainless-steel whip is field-tuned for lowest vswr and double-locked with stainless-steel set screws. The antennas feature 3/8-24 ferrules to fit standard mobile mounts and are power-rated at 500 Watts PEP for top mobile performance.

For further details, contact *Valor Enterprises, Inc., 185 W. Hamilton St., West Milton OH 45383.* Reader Service number 484.

RETICON ACTIVE FILTER

Applied Invention is the source for the recently introduced Reticon R-5620 programmable active filter—a complex MOS integrated circuit. The R-5620 uses switched-capacitor technology to synthesize a two-pole pair active filter that requires no external components and operates over the range of 0.05 to 25 kHz.

The five basic filter types: low-pass, high-pass, bandpass, band reject, and all-pass can all be implemented by the R-5620, and a programmable sine-wave oscillator is also possible.

Switched-capacitor filters (SCFs) are analog filters in which fixed resistors are replaced by time-division-variable switched capacitors, resulting in very stable filters that can be tuned with a variable clock source.

The simple programmability of this new SCF makes it attractive for computer-controlled synthesizers and other analog/digital systems applications.

For additional information, contact *Applied Invention, RFD #2, Route 21, Hillsdale NY 12520.* Reader Service number 483.

YAESU'S ACTIVE ANTENNA

Yaesu Electronics Corporation recently announced the introduction of the FRA-7700 active antenna for the FRG-7700 deluxe HF receiver.

The FRA-7700 utilizes a four-foot (1.2-meter) whip in conjunction with a low-distortion MOSFET preamplifier, providing shortwave reception for receiver owners unable to erect an outdoor antenna. The FRA-7700 includes front-panel gain control, tuned-circuit peaking, and a preamplifier on/off switch for maximum versatility.

For details on the FRA-7700, contact *Yaesu Electronics Corp., PO Box 49, Paramount CA 90723.* Reader Service number 486.

RT-1100 MULTIMODE TERMINAL

DGM Electronics has just introduced the RT-1100 receive terminal for Baudot, ASCII, and Morse. The RT-1100 converts the audio from your receiver, decodes it, and displays the words on a video monitor or TV set (using rf modulator). The RT-1100 incorporates an active filter demodulator with scope-tuning outputs. It will copy 170-, 425-, and 850-Hz-shift RTTY signals at speeds of 60, 66, 75, and 100 wpm on Baudot and 110 baud on ASCII. The unit will copy 6-60 wpm Morse signals using automatic or manual speed tracking. The RT-1100 has a parallel ASCII printer output for hard copy. The video output provides 16 lines of 32 characters per line with 2 pages. The second page is stored in memory and can be recalled by using the page 1-2 switch on the front panel. The unit has a built-in 110-V-ac power supply and is housed in an attractive 3" × 10" × 10" case with brushed, anodized front and rear panels. The cover is a gray wrinkle finish. The unit comes with a one-year warranty on parts and labor.

For more information, contact *DGM Electronics, Inc., 787 Briar Lane, Beloit WI 53511; (608)-362-0410.* Reader Service number 477.

MOBILE ANTENNA CONVERTER

JL Industries has just announced their new X-Panda-Five mobile antenna adapter, which enables the owner of a Hustler, Hy-Gain, or similar mobile antenna to convert his antenna to a five-bander by adding resonators.

The X-Panda-Five consists of a precision-machined aluminum hub fitted with five rustproof 3/8" by 24" studs made from high-tensile-strength carbon steel. The hub is attached to the antenna mast, and each of the five resonators screws onto the hub. One resonator is mounted vertically and four are mounted horizontally.

When the adapter is installed on your antenna, you can use either regular or super-size resonators and change bands without leaving the driver's seat. This assumes, of course, that you pre-tune each resonator to your favorite operating frequency in that band. No antenna tuner is required.

The X-Panda-Five also makes a good antenna for apartment houses and condominiums when fitted with the appropriate resonators and ground planes. It can be used to make a multiband antenna system for vans, campers, motor homes, and travel trailers.

For more information, contact *JL Industries, PO Box 030413, Fort Lauderdale FL 33303.* Reader Service number 490.

DGM Electronics' RT-1100 receive terminal.

ANTENNA COUPLER

Wayne Research & Development has announced the availability of a new antenna coupler that replaces the center insulator of a balanced rf antenna system. The Wayne B-T-L antenna coupler contains an air balun, a tapped inductor, and a variable capacitor. The coupler is housed in an ABS plastic box with a removable lid for inspection and servicing. The strain insulator is made of Delrin® plastic.

With the aid of graphs in the instruction booklet (supplied) and an swr meter, the user can design a matching network to match the low impedance of his wire beam or the high impedance of his loop antennas. Using the network as a T or an L, the Wayne B-T-L antenna coupler will match impedances over a frequency range from 1.8 to 30 MHz.

The insertion loss is not more than −0.006 dB from 1.8 to 25 MHz, and minimal from 25 to 30 MHz. The introductory price is $49.95. For further information, contact *Wayne L. Jamison W5FJS, Wayne Research & Development, PO Box 75144, Houston TX 77234.* Reader Service number 478.

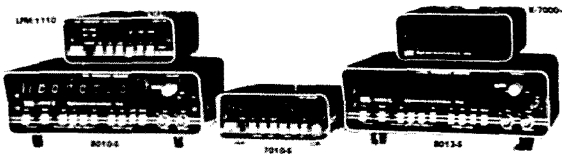
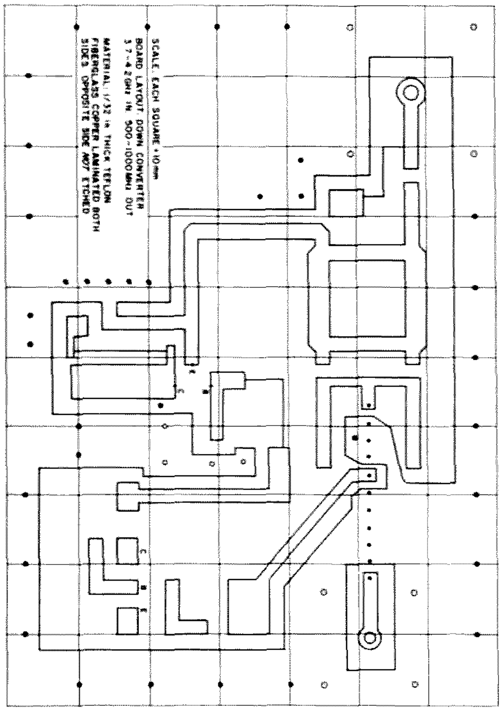
MODEL LFM 1110 Low frequency multiplier. A frequency counter accessory enabling low frequencies to be counted faster and more accurately. Has low pass filter for off-the-air tone-squelch measurements. BNC input output.

#LFM 1110	Low frequency multiplier 115VAC 12VDC	$125.00
#NiCad 1110	internal NiCad battery pack	25.00
#BNC-PC	3 ft 50 Ohm BNC patch cable	9.95



NOW IN STOCK

CORRECTIONS



G. W. Legel's (N6TO) article "Dissertation Upon Roast Pig" (October) offers an interesting and useful suggestion for transformer salvage, but ignores an extremely important personal caveat.

Old transformers were frequently filled with polychlorinated biphenyls (PCBs). This is a dangerous, toxic material that should be dealt with by trained professionals. Old, oil-cooled transformers must be presumed contaminated. Unless they bear a green certification sticker, they should not be handled by amateurs under any circumstances.

Tom Archer KC8MR
Huron OH

The $100 TVRO receiver is a real winner. I'm going to build one, except for one small detail. The August issue of *73* (on page 64) has the layout of the downconverter used in Rex's "Cheap Trick." The only problem is that in Fig. 4 the scale is 10mm per division. The printed version is 128mm long when it should be 100mm. I'm sure that was done for clarity, but it is hard to interpolate 128mm to 100mm. I'm also sure that you know the dimensions at the frequency are critical.

What I'm asking is if you have an actual-size drawing from Steve Gibson, could you print it in the next issue at 1:1? Please??

David Lawson WA1YMC/5
Dallas TX

Here you go.—*Ed.*

Fig. 1 in "The Vertical Deuce," on page 81 of the September issue, was drawn incorrectly. As drawn, closing the relay would put a short across the center conductor and braid of the feedline. Instead, the braid should be connected directly to ground and the center conductor should be hooked up to the coil at the opposite end from the antenna.

Avery Jenkins WB8JLG

REVIEW

THE HF 10/160 SOLID-STATE PLL TRANSCEIVER

The voice at the other end of the telephone line belonged to Bruce Stwertnik, president of National Communications Group, Inc., importers of that nice little NCG 15-meter monoband rig which was reported on in the July, 1981, *73*. Now, it isn't unusual for Bruce to call and chat, but I sensed that he had something special up his sleeve this time. After the usual chitchat, he dropped the other shoe: "Jim, I've just got a new rig in from Japan, how'd you like to put it through its paces?"

At the hint of something new and possibly different, my mind began racing with questions such as what kind of rig? For which bands? How much power? What does it look like? How does it play? What features? You know the kind of things I mean... but I barely managed to get a few of them across to Bruce as I quickly stammered a "Sure, I'd be delighted!"

Bruce hastened to explain that this rig would be a scoop for *73* since there are only two in the States at the moment, but a lot more on the way. I was to get the first one to test and Bruce was to keep the other for himself. As a matter of fact, the English-language manuals weren't quite ready yet, he said, so I could expect only a spec sheet and a brief translation of some of the features, operating hints, and comparisons with similar rigs currently on the market.

The NCG HF 10/160 transceiver is much as one would expect. It is definitely a new-generation transceiver, with solid-state circuitry and PLL frequency synthesis. And apparently, if one can judge from the pictures in *CQ-Ham Radio*, the Japanese amateur radio magazine, it has been in use in Japan for some time.

Physical Description

The transceiver is manufactured by Matsushita Electronic Industries Company Ltd., a parent company of Panasonic, among others. It measures approximately 13 inches wide by 5-1/2 inches high by 16 inches deep (if you count the massive rear-panel heat sink) and weighs just shy of 21 pounds... but wait a minute: that includes both ac and dc supplies—built in! No need for an external supply, whether you are mobile or fixed. The usual tilt bail on the bottom to raise the rig to a comfortable angle for viewing the front panel is provided, and there is the side carrying handle intended to make the rig conveniently portable. The case is dull black and has a vaguely military, i.e., functional, look. Perhaps the first thing you notice is the centrally-located spinner dial on the front panel, just below the large digital readout frequency display whose green alphanumerics are nearly one-half inch high and are easy to read. There are prefix letters ahead of the numbers when the rig is operated in its various modes: "C" for CW, "U" for upper sideband, and "L" for lower sideband.

The VOX sensitivity, VOX delay, and anti-VOX controls are on the left-hand side of the rig, and the VOX sensitivity control knob has a concentric switch for the 100-kHz frequency marker provided in addition to the synthesized readout, because this permits the on-board phase-locked-loop circuitry to be zeroed against WWV, for example.

The new bands are provided for as well, and the rig covers all amateur frequencies with generous overlap on the ends for MARS or other use. The S-meter dial is in the upper left-hand corner, and indicates relative power output or ALC (your choice) in the transmit mode and S-meter readings in the receive mode. As a matter of fact, I think you would be particularly pleased with the S-meter, as it doesn't seem to be particularly scotch or particularly generous. Somehow, I have the feeling that it is about right—and consistent—from band to band.

The power on-off switch is a toggle in the upper left-hand corner; below the meter is a row of switches that control receiver functions such as noise blanker, meter scale, fast-slow agc, and tuning rate. The tuning device is an optical chopper which permits simple dial lock to a desired frequency simply by disengaging the manual dial. There is a tuning-rate switch that permits you to tune each band in 25-Hz, 100-Hz, or 1-kHz increments. Right next to that manual selector is an auto-tuning switch that functions in the up or down modes, and changes frequency at the rate selected by the adjacent rate switch. I never thought I would need—or want—such a device, but it's handy and I use it a lot.

Below the switches just mentioned are the microphone connector (standard Japanese 4-pin) and the phone jack (standard 1/4-inch diameter) right next to it. Then comes the key jack, which uses the smaller-diameter plug of the size used to plug in speakers and the like (I believe it is .168" diameter). Fortunately, another rig I tested recently had this size key jack, so I was ready, but on the *front* panel? Why there of all places? The answer is simple—convenience; I realized that as I recalled the many times I have fumbled around the back of a rig in the dark trying to find the key jack.

The HF 10/160 has a built-in speaker placed on the bottom plate of the rig, and a jack for an external speaker should you wish to use one. I found the audio quality to be quite good, even with the small enclosed speaker... and that certainly is the way to go for portable/mobile... unless or until you wear headphones, of course. An external speaker is normally used in my shack, however, so I used that for the evaluation.

Next to the key jack is the mode-selector switch—permitting wide or narrow CW and upper or lower sideband... you have to choose which. On the dial escutcheon you will find two small push-buttons that activate the dial lock (left button) and the TX/RX REV switch. On the upper right-hand side of the panel you will find the Delta F switch and the RX offset switch (RIT).

The Delta F control corresponds to the receiver incremental tuning control (RIT) on the other rigs. By pushing the switch, a red LED comes on to show that the circuit is activated. Now, by varying the Delta F knob, you can adjust the receive frequency higher or lower than the dial-set frequency by about 1 kHz.

The TX/RX REV control permits further adjustment of the transmit or receive frequencies separately. When the switch is depressed, a red LED is illuminated to show that the circuit is active. Here's how it works. Suppose you want to leave your transmit frequency where it is but wish to change the receive frequency. Push in the TX/RX REV switch to lock the transmitter frequency on the existing dial setting. Now the receive frequency can be adjusted by the main tuning dial. This gives the effect of a dual vfo, and permits you to set the transmitter "up five," for example, when working DX on a split frequency, and then use the receiver and main dial to tune the DX station. If you wish to listen to *your* frequency momentarily, turn the TX/RX REV switch off, and presto, you're back on the transmit frequency with the receiver.

The memory-selection push-buttons are next, and require a separate discussion—so we'll come back to them later. You should know, however, that you can store up to four different frequencies and scan between any part of them at a variable rate, using "autowatch."

If you really want to get fancy about all this, you can use all these features in concert: TX/RX REV, Delta F, and memory select. I am sure that an accomplished dial twister and button pusher could really play a symphony on this rig after a few evenings of practice. Versatility is the name of the game with the HF 10/160 from NCG, and it's unlikely you will run out of permutations and combinations to try.

The main control knobs of the transceiver lie below the switches, and include in the top row: transmit frequency variation (Delta F), i-f tuning (± 1 kHz) and the audio/rf gain controls on concentric shafts for the receiver; and in the bottom row: the mike gain/CW carrier-control knob, the audio-compressor/speech-processor control, and finally the bandswitch covering 1.8-29.7 MHz.

I found that all controls fall more or less conveniently to hand, and that if you have used any of the modern solid-state rigs from Japan, you will find everything about where you expect it. I was impressed with the nice manual tuning feel and the utter simplicity of using the rig.

Electrical Description

The NCG HF 10/160 contains 30 integrated circuits, 6 FETs, and 124 diodes/transistors. Power consumption is nominally 50 Watts on receiving in the ac mode, and 0.6 Amperes current drain in the dc mode. Transmitting consumes 550 Watts in the ac mode, and 20 Amperes current drain in the dc mode. Nominal dc voltage requirements are 13.8 volts (negative ground) at 20 Amps—enough to require that you have a battery charger, if portable, or a good alternator system if mobile and operating at the full-power capability. Ac requirements are the usual 120 volts, 50 cycles.

Band Coverage

The HF 10/160 covers 1.8-2.0 MHz in the 160-meter band, 3.5-4.0 MHz in the 80-meter band, 7.0-7.3 MHz in the 40-meter band, 10.0-10.5 MHz in the 30-meter band (providing some general reception, too), 14.0-14.35 MHz in the 20-meter band, 18.068-18.168 MHz in the 17-meter band, 21-21.45 MHz in the 15-meter band, 24.89-24.99 MHz in the 12-meter band, and 29.0-29.7 MHz in the 10-meter band.

Stability is given as less than ± 200 Hz within one hour and less than ± 20 Hz after one hour. A comment about the extraordinary frequency stability was received from a ham on 40 meters who had been listening to me for a half an hour. He mentioned that my frequency as measured on his frequency meter had not changed one cycle during the entire time he had been monitoring! This means that both voltage and temperature stability is excellent. The comment, by the way, was unsolicited.

Transmitter Description

The final-stage input is 200 Watts (160-12 meters) and 100 Watts on 10 meters. Balanced-type modulation is used, and carrier suppression is more than 40 dB. Sideband suppression is more than 50 dB, and spurious radiation is at a level below −40 dB. Microphone impedance is about anything you want, and a range of 600 to 50k Ohms is acceptable. The output connector for rf is the usual 50-Ohm UHF type SO-238.

NCG's HF 10/160 transceiver.

SOME FEATURES COMPARED

Feature	NCG 10/160	TS-830	FT-101
Tuning	PLL-synthesized	Vfo (capacitor)	Vfo (capacitor)
Power Supply	Ac/dc built in	Ac	Ac (dc optional)
Weight	21 pounds	30 pounds	32 pounds
Dimensions (H × W × D)	5.2 × 2.68 × 12.44	5.24 × 13.11 × 13.11	6.18 × 13.58 × 12.83
Frequency memory	Yes	No	No
Autoscan	Yes	No	No
Dual vfo	Yes	No	No
Tuning rate	3-step	N/A	N/A
Passband tuning	No	Yes	Yes
I-f tune	Yes	Yes	No
Notch filter	No	Yes	Yes
CW/af	Yes	No	Yes
Tone Control	No	Yes	No
Drift-free tune	Yes	No	No
All solid state	Yes	No	No

Receiver Description

The receiver is a single-conversion superheterodyne of the type well known for its good sensitivity and lack of images, yielding a factory-measured sensitivity figure of less than − 12 dB (.25 V) at 10-dB S/N ratio. The i-f frequency is 9.0007 MHz on CW and 9.000 MHz on phone. Selectivity on SSB or wide CW is 2.2 kHz at − 6 dB, less than 3.0 kHz at − 20 dB, and less than 6 kHz at − 60 dB down, for a shape factor of about 2.7. On narrow CW, the figures are 400 Hz at − 6 dB, 1 kHz at − 20 dB, and 1.6 kHz at − 60 dB, respectively. This gives a shape factor of about 4:1 for narrow CW. The narrow CW option could not be observed at the time of testing because the sharp filter had not yet been received.

Spurious images are down more than 60 dB, i-f rejection is likewise more than 60 dB, and other spurious response is down more than 70 dB.

With the built-in speaker (nominal 8-Ohm impedance), the audio output power is 0.5 Watts (10% THD) and with an external speaker, the audio output power is 1 Watt (10% THD).

Using the Rig

This report is necessarily a preliminary and admittedly sketchy evaluation because the manual I have is in Japanese. The English versions should be available (along with the rigs) by the time you read this. In spite of, or perhaps because of, the lack of an English-language manual, I found that I paid more careful attention to the drawings and photos than usual. These are abundantly clear, and it would be almost impossible to set up the rig incorrectly if you have had any experience at all in putting a "transceiver-from-the-box" on the air.

Carefully unpacking the rig from the usual sanitary plastic bags and foam-sheltered security of the container, I found a separate bag containing the microphone and still another small box with the ac and dc power cords inside. Selecting the ac cord, I plugged it into the polarized multi-pin socket on the back. My ground wire was put on the terminal, underneath the usual washer and wing nut. The microphone plugged into the usual 4-pin front-panel connector.

One obtains a first impression of any rig as it comes from its cocoon, and this one was no exception. Its general appearance, weight, and feel lend the impression that it is functional and business-like, with its matte black finish and vaguely military look.

Being a CW man at heart, I wanted to try that mode first, so I plugged my electronic keyer into the rig, switched the operate switch to VOX, and set the sensitivity control and delay control for comfortable semi-automatic break-in. Keying the rig produced a fine sidetone—pleasant to the ear—and my power-output meter showed a power output of approximately 70 Watts on 40 meters. A quick twist of the Mic Gain/CW CAR control brought the output to 100 Watts. The stations I worked on 80, 40, 20, and 5 meters all reported fine keying and good solid signals with a nice CW note.

The only small objection I had was from an operator who claimed that on the initial make (when the relay came on) there was a slight frequency warble which disappeared once the relay held in. (This will be corrected in subsequent production rigs.) However, if you choose to set the VOX delay to a long duration, there will be only one little warble at the beginning of the first character. This would also be true, of course, in the manual mode, and thereafter you should hear no complaints. Not having heard this myself, I can only report what that one operator told me. Significantly, perhaps, no one else mentioned it.

I was somewhat bothered by the lack of a narrow-CW filter, but I found that I could operate in all but the worst of crowded conditions by using the i-f shift control to move the i-f window into a better location with respect to the carrier. This gave the impression of an improved selectivity by removing part of the bandpass through which extraneous signals could slide. All in all, I found CW operation very satisfactory, and was delighted to be able to work about anything I could hear. Although I did not find the sidetone pitch and volume controls which are internal, I must confess that I didn't search for them either. Once the English-language manual arrives, it will be a snap to adjust them to one's own special comfortable listening level and tone. With earphones on, I found everything to be exactly right, so I didn't bother trying to change them.

Single-sideband operation is where this rig really shines. I am not much of a phone operator, and because of this I was perhaps a bit overconcerned about the modulation and signal levels that I would be able to produce. I needn't have worried; each report was outstanding.

The first evening of sideband operation went something like this: "W1XU, this is W—; you are five by nine here. By the way, what rig are you running? The audio is outstanding!" (Mic Gain control positioned at 10 o'clock.)

"W—, this is W1XU right back. Thanks, OM, for the fine report. The rig is a new one undergoing test for 73. I'm not at liberty to tell you the make and model just yet, but I can tell you it is nominally a 100-Watt-output rig, made offshore."

(Breaker)"W1XU, this is K—; what kind of rig did you say you were running? The audio is superb. Are you running a processor?"

"K—, thanks for the good report. I appreciate it. Can't tell you what the rig is, but you'll read about it in 73 one of these months."

(Breaker) "W1XU, this is W—. I just wanted to tell you that I have been listening to you for half an hour, and your frequency is rock steady. You haven't varied by one cycle since I started listening. I also wanted to tell you that your rig is super, whatever it is."

(Later that evening) "W1XU, this is WA—. Your audio certainly doesn't sound any better with that compressor in your circuit. In fact, it sounds better without it. Are you sure you don't have some audio processing? It's crystal-clear and has magnificent 'punch.' "

Rather than bore you with further reports of the same or similar content, I'll just mention that every report has been outstanding. I have been very careful about avoiding requests for an audio quality report, and each one was unsolicited. In spite of the fact that I consider myself a dyed-in-the-wool CW operator, this rig has gone a long way to turn me back to SSB. Maybe it will help to understand that when I admit that my voice is one of those mid-range voices that could be described as soft-spoken. It does not "talk up" a rig like many that you hear. In fact, I usually use a mike amplifier to help out... but with this rig it surely isn't necessary and probably is not desirable.

Of course, being solid-state, no tune-up is required, and full output is achieved into a matched antenna. I did not notice any swr shutdown protection at swr values up to about 1.5 to 1. Inadvertently, I once attempted to transmit with the antenna shorted to ground. Obediently, the finals shut down, and—fortunately—no damage was done. This was immediately obvious by the power output meter, which didn't even flicker. Not having any swr values in the 3:1 range, I can't be sure at what point shutdown began, but I would guess that 3:1 would result in a power output of about 50 Watts or less ... in other words, a progressive protection. Nice.

The memory function had me a bit perplexed, but I got brave enough to finally give it a whirl. I dialed in two frequencies about 50 kHz apart and committed them to memory as follows: 14.007 on dial, punch the Write button, followed by button 1. 14.007 is now in memory 1 and also displayed on the screen. (Punch the vfo button and you are able to dial in another frequency.) This time, I dialed up 14.012, depressed Write and button 2, followed by vfo. 14.012 was now in the memory 2 location. Next, I wanted to put in two more frequencies in memories 3 and 4... which I did, according to the previously described method. Now, by merely selecting any of the four memory buttons, I could instantly recall the frequency in memory. Nothing special, you'll agree—and about like any transceiver with memory.

Now, what about the autowatch function? Well, I pushed it—and guess what? The receiver goes into a scanning mode and scans between the two frequencies in memories 3 and 4! It scans very slowly—I would guess no faster than about 10 Hz/second. When it reaches the top frequency it returns to the lower one and begins scanning again. Although I don't have any particular need for that feature at the moment, I can visualize a few occasions when it might be very worthwhile to have. For example: Suppose you are looking for a friend on a particular frequency, "plus or minus QRM." Just set two frequencies above and below the intended frequency and punch autowatch! When your friend comes on, you'll hear him because the scan rate is slow enough to permit call identification before it moves on. Neat.

Frankly, I have not used audio compression except on some DX contacts, where the reports have indicated an improved readability—perhaps because of the higher average power output. There were no adverse comments as there had been on local contacts.

So far, I've not been able to find the time to install the rig in the car... but may do so in time to drive to a hamfest this coming weekend. It's a longish trip—about 400 miles each way—so that should provide ample opportunity to give the rig a real mobile shakedown. I have no reason to believe that it will perform other than spectacularly.

Is this rig for you? Well, of course, it depends upon what you are looking for. Certainly it has many nice features, including some that aren't available in the run-of-the-mill modern transceiver, and it is rugged and functional. The price is competitive, as it is squarely in the range of similar transceivers. I felt the dial was very satisfactory, and the knobs, switches, and controls equally so. The only picky-picky complaint I have (and this wouldn't bother anyone else, I'm sure) is that the small knobs have skirts that are decorated with a plastic trying to simulate metal... and it looks like plastic, not metal. If I were the manufacturer, I'd forget trying to dress it up with this charade. Leave 'em all black, and they'll be that much better for it.

You may find there is enough information available on the metering modes; all you get is rf output, S-meter, and ALC information. Upon further consideration, what more do you really need?

With this article is a handy comparison chart for you, between the HF 10/160 and two other contemporary rigs in the same price class. Look it over and decide for yourself whether you're interested. If you're like me, I think you will be... very much so!

ICOM IC-290A/E ALL-MODE 2-METER TRANSCEIVER

The Icom IC-290A/E (A is the American version and E is the European model) is just what the doctor ordered if you are looking for an all-mode 2-meter rig. It has all the features a 2-meter op could want, and even a seasoned VHF operator would be pleased with the unit. The capabilities of the IC-290 are astounding for its small size. It operates USB, LSB, FM, and CW from 143.8 MHz to 148.2 MHz. In addition to two completely independent vfo's the 290 features five memories and a flexible band-scanning system. Yet, at 64 mm (H) × 170 mm (W) × 218 mm (D), it is smaller than many FM rigs.

On the Road

I had been wanting to try 2-meter SSB mobile for years, and finally had the chance the day the IC-290 arrived. So, I installed the radio and headed out on a business trip from Peterborough NH to New York. Before leaving, I programmed the memories for five of the repeaters I might encounter enroute and put vfo A on 144.200 MHz, the calling frequency for SSB. I set vfo B on 146.52 and set the scanner for memory scan. This allowed me to scan all seven frequencies.

Although SSB during the day is not as busy as FM, there is still a considerable amount of activity, with new stations on the air every day. I could leave the rig in FM scan, and when a station came on 144.200 MHz the squelch would open and all I had to do was switch to USB to see who was calling. This system worked very well. I worked several stations between New Hampshire and New York. The added range on 2 SSB and the lack of beepers, timers, and kerchunkers is truly a pleasure. My friends on "the low end" may be upset by my publicizing their secret, but there is plenty of room for everyone. It reminds me of a bumper sticker seen on a car up here in New Hampshire after a particularly large influx of "flatlanders." "Keep NH a Secret," it read. Well, it's hard to keep a secret about something so great, and 2-meter SSB is the same.

Technical Highlights

The rf amplifier and first mixer circuits of the IC-290 use MOSFETS which allow for a receiving system that is more sensitive than any other 2-meter multi-mode rig I have tried. Unlike other transceivers, the 290 does not need a preamplifier for successful operation. I took the rig with me on a trip to Boston and tried to work a repeater in NH while in the back yard of another that was 15 kHz away. Contrary to other receivers that I had put through the same test, the IC-290 came through with flying colors. The receiver features selectable agc in SSB and CW plus a noise blanker that worked very well in removing ignition noise that was being radiated by my auto and adjacent vehicles as well.

The Icom 290 has two continuous-tuning vfo's. What this means is that when you get to the end of the tuning range (i.e., 148.200) the vfo automatically switches to the bottom edge (143.800). This feature saves a lot of time if you are on 147.51 MHz and you want to QSY to 144.220 MHz. In the SSB and CW modes, quick tuning in 1-kHz steps is available or, with a push of the front panel tuning rate switch, fine tuning in 100-Hz steps. On FM, the tuning rates are 5 kHz and 1 kHz. The tuning knob has click stops which allow for eyes-on-the-road tuning. A

priority switch allows you to sample any one of the memory channels every five seconds, regardless of whether the scanner is on or another frequency is being listened to. The S-Meter/Rf-Output indicator is of the currently-popular LED-bar type.

The transmitter in the IC-290 has a high output of 10 Watts. By pulling out on the squelch knob, you are in low power which comes through from the factory set at 1 Watt and is internally adjustable. Transmitted audio reports that I received were all favorable. The repeater offsets are controlled by two front panel switches. To the left of the main tuning knob is a three-position offset switch, selecting either up, down, or simplex. The offset frequency is selected by placing the mode switch in the Offset/Write position and dialing the main tuning knob to the desired offset frequency. Then you return the mode switch to the FM position and your offset is set until you change it. Internal transmitter controls include everything you should need from deviation-adjust in FM to CW sidetone-adjust.

Icom has provided an excellent operating manual. It includes inside photographs with all internal adjustments very well labeled. In fact, the manual is so good that Jeff DeTray WB8BTH used it to describe to me over the phone where the deviation pot was located. The manual with all its descriptive pictures was at his house and the rig was on my bench. He found the pot and described to me exactly where it was in just a matter of seconds. There is no need for an extra-cost service manual just to make adjustments.

With the IC-290A/E, Icom has once again demonstrated its ability to pack many features into an extraordinarily small package. And yet they've done it without sacrificing operator convenience. As the sunspot cycle declines and all-mode rigs proliferate, we can expect to see more and more SSB and CW activity on 2 meters. Radios like the IC-290 will bring lots of new blood to the low end of two.

For further information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

HF ANTENNAS FOR ALL LOCATIONS

L. A. Moxon G6XN scarcely needs an introduction to at least two generations of antenna enthusiasts. His fascinating descriptions of antennas of all kinds, ranging from beams to vertical and from wire antennas to space-saving and "hidden" antennas, have inspired thousands of radio amateurs in this country and abroad to try their hand at just one more antenna. More often than not, the G6XN antenna will exactly fit the requirements and will perform at least as well as—and sometimes better than—whatever you may have tried before.

Les Moxon's articles, sketches, and ideas have appeared in the RSGB publications, in *QST*, and in collections and manuals everywhere. Now, at last, we have the man all by himself in a book that is bound to become a must for the bookshelf of every right-thinking antenna experimenter: *HF Antennas for All Locations*, published by the Radio Society of Great Britain, 35 Doughty Street, London WC1N 2AE, England ($12).

Here is a book you can really get your teeth into—one that you can use to answer questions you may have about a particular aspect of theory or to build a practical antenna from a concise sketch with exact dimensions for the frequency of your choice. Not only that, the English seem to have a unique way of making difficult subjects seem very simple, and Moxon's book is no exception. His explanations and drawings of the ionosphere, for example, are quite fascinating, and show a three-dimensional space in two dimensions by some very clever art work.

Let's for just a moment peek into the contents and see what's there that may interest you and have application to your particular situation. (I'm convinced that Les has something for every antenna taste and persuasion.) The book is divided into two basic parts. Part I is titled "How antennas work," and covers in ten chapters the following subjects: Taking a new look at HF antennas; Waves and fields; Gains and losses; Feeding the antenna; Close-spaced beams; Arrays, long wires, and ground reflections; Multiband antennas; Bandwidth; Antenna design for reception, and The antenna and its environment.

Part II covers "Theory into practice," and includes these chapters: Single-element antennas; Horizontal beams; Vertical beams; Large arrays; Invisible antennas; Mobile and portable antennas; What kind of antenna?; Making the antenna work, and Antenna construction and erection.

As you can see, there's enough material there to fuel your winter's needs for reading matter, and sufficient practical "how to" information to occupy several year's worth of summertime building frenzy.

Take the first chapter in Part I, for example, which invites the reader to take a *new* look at HF antennas. Just what does Les Moxon mean by a *new* look? Well, let him speak for himself.

"Amateurs have been using HF antennas for 60 years or more so that some slowing down in the rate of progress might be expected. As evidence of this, some of the best antennas in use today were designed 20 to 30 years ago yet, impelled by strong incentives, the search for the 'better' ones continues unabated. At times of slow progress it is not a bad idea to look at problems from new angles, and a possible first step is to erase from one's mind the picture of 'things as they are' and concentrate, for a few moments at least, on the way one would *like* them to be. Listing the reasons why they are not and challenging each in turn can be good fun; moreover, before accepting once again the status quo, one feels entitled to convincing evidence that there are no alternatives.

"In the following pages the reader will find few such proofs but instead several challenges to existing beliefs and practices, 'proof of impossibility' being reserved mainly for the antenna gain figures frequently claimed by authors and advertisers."

Les then goes on to explain that weight, size, and cost of beam antennas must be considered to be fair game for investigation and that a reduction in these values *without compromising performance* is a worthy goal. Another goal is minimizing interfering signals, and G6XN questions whether that goal is incompatible with the goal of increased gain. Today's thinking suggests that there is no answer, but Les points out a new and striking possibility: Why not change the antenna characteristics between transmitting and receiving?

In fact, the contents of the book suggest that the desired objectives can be met with *dipole* elements only, and that loops or other configurations are not necessary—provided that one doesn't think that a *straight* dipole is necessary!

Well, this is just a taste of what the book holds, and it goes into great detail explaining how new configurations can be achieved, what they might look like, and what may be possible.

In Part II, there are some concrete examples given on the construction of minimum-size antennas that more or less fulfill the promise of the earlier portion of the book. Whatever your antenna problem may be or however limited your space or budget, G6XN has something for you.

No one suggests or would dream of suggesting that *HF Antennas for All Locations* is a panacea for antenna problems, but it is interesting and requires some study. I'd be willing to bet that seventy-five percent of us could greatly improve our HF antenna installations by reading what Les Moxon has to say. Ask your book dealer today to get you a copy. Reader Service number 493.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CONNECTICUT QSO PARTY

Starts: 1100 GMT December 4
Ends: 1100 GMT December 5

Sponsored by the Candlewood Amateur Radio Association (CARA). Phone and CW are considered to be the same contest. Stations may be worked once on each band and each mode.

EXCHANGE:

Send QSO number and ARRL section or Connecticut county.

SCORING:

Out-of-state stations multiply total QSOs by the number of Connecticut counties worked (8 maximum). Connecticut stations multiply total QSOs by the sum of ARRL sections and provinces. Additional DX contacts count for QSO points but only one DX multiplier overall is allowed. W1QI, the club station, will be operating CW on the odd and SSB on the even hours, and counts as 5 points on each band and mode. Novice contacts count as 2 points each and OSCAR contacts count 3 points each.

FREQUENCIES:

CW—40 kHz up from the bottom of each band.

SSB—3927, 7250, 14295, 21370, and 28540.

Novice—3725, 7125, 2119, and 28125.

ENTRIES & AWARDS:

A Worked All Connecticut Counties certificate will be awarded to each station working all the counties. Other awards given as usual, minimum of 5 QSO points! Logs must show category, date/time (GMT), stations, numbers, bands, QSO points, and claimed scores. Enclose a large SASE for results. Logs must be postmarked by January 2nd and sent to Steve Grouse KA1ECL, 3 Queens Court, Danbury CT 06810.

CANADA CONTEST

Starts: 0000 GMT December 19
Ends: 2400 GMT December 19

Sponsored by the Canadian Amateur Radio Federation (CARF), the contest is open to all amateurs and everybody works everybody. Entry classes include single-operator allband, single-operator single band, and multi-operator single-transmitter allband. There are separate single-operator QRP (5 W dc, 10 W PEP out) and single-operator non-Advanced amateur classes.

Use all bands from 160 to 2 meters on CW and phone combined. All contacts with amateur stations are valid. Stations may be worked twice on each band, once on CW and once on phone. No crossmode contacts, and no CW contacts in the phone bands are allowed.

EXCHANGE:

Signal report and consecutive serial number starting with 001; VE1 stations also should send their province (NS, NB, PEI).

SCORING:

Score 10 points for each contact with Canada, 1 point for contacts with others. VE0 counts as Canada. Score 10 points for each contact with any CARF official news station using the suffix TCA or VCA. Multipliers are the number of Canadian provinces/territories worked on each band, on each mode (12 provinces/territories × 8 bands × 2 modes for a maximum of 192 possible multipliers). Contacts with sta-

NEWSLETTER OF THE MONTH

This month's winning newsletter is the *Printed Circuit*, published by the Lubbock Amateur Radio Club in Lubbock, Texas.

As well as its unique masthead, the *Printed Circuit* offers a variety of features not found in most newsletters. For example, one issue features a full-page profile of a local old-timer, which was followed by a column on personal computers.

Not leaving out other areas of interest, the editors of the *Printed Circuit* included a story on amateur participation in a recent disaster drill and devoted another full page to DX news and propagation predictions.

And that's not all—There is also a regular technical column, public service announcements, repeater update, puzzles, and a monthly activity calendar.

One sure way of divining the success of a publication is by the activity of its letters section, and the *Printed Circuit* is not lacking in that area, either. Many newsletter editors must dream of getting the number of letters received by the *Printed Circuit*.

To top it all off, the *Printed Circuit* publishes a Q & A session with "The Old Ham." The Old Ham addresses timely and pertinent subjects, such as what to do in a Toronado warning and how to tell a Toronado from a Chevy.

Hats off to Becky Swann WD5KBO and her staff for putting out a newsletter with more stuffed into it than a five-flavor banana split.

73 encourages clubs to send in their club newsletters. Just address them to *73*, Pine Street, Peterborough NH 03458. Keep us up to date with what is happening in your area, and maybe even win the Newsletter of the Month contest.

tions outside Canada count for points but not multipliers.

FREQUENCIES:

Phone—1820, 3770, 3900, 7070, 7230, 14150, 14300, 21200, 21400, 28500, 50.1, and 146.52.

CW—1810, 3525, 7025, 14025, 21025, 28025, 50.1, and 144.1.

Suggest phone on the even hours (GMT), CW on the odd hours (GMT). Since this is a Canadian-sponsored contest, remember to stay within the legal frequencies for your country!

AWARDS:

A plaque will be awarded to the highest score single-operator, allband entry. Certificates will be awarded to the highest score in each category in each province/territory, US call area, and DX country.

ENTRIES:

A valid entry must contain log sheets, dupe sheets, a cover sheet showing claimed QSO points, a list of multipliers, and a calculation of final claimed score. Cover sheets and multiplier check lists are available. Entries should be mailed within one month of the contest, with your comments, to: CARF, PO Box 2172, Stn. D, Ottawa, Ontario K1P5W4, Canada.

Results will be published in *TCA*, the Canadian amateur magazine. Non-subscribers may include an SASE for a copy of the results.

RESULTS

1982 A5 *MAGAZINE* WORLDWIDE DX SSTV CONTEST

1st DX	FM7CD	1622 pts.
1st US	KE1Y	810
2nd	VE4ADG	453
3rd	KB6WP	410
4th	VE3JW	368
5th	WD9IPX	331

(63 entries total were received)
Next SSTV contest is the WAS SSTV in January

2ND ANNUAL 40-METER WORLD SSB CHAMPIONSHIP

Starts: 0000Z January 8
Ends: 2400Z January 8

SPONSOR:

73, Peterborough, New Hampshire 03458.

MISCELLANEOUS RULES:

Work as many stations as possible on 40-meter phone during the specified times of allowable operation. The same station may be worked once. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All the multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your log(s) and on your summary sheet. Off periods are no less than 30 minutes each.

OPERATOR CLASSES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental 48 US states and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

1 QSO point is earned for each station worked in the continental 48 US states and Canada or within your own country. All other contacts are two points each. List points for each contact on your logsheet.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum), each Canadian province or territory (13 maximum), or DX country worked.

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include a contest log, a contest summary, and multiplier checklist. We recommend that contestants send for a copy of the contest forms. Send an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 12, 1983.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

AWARDS:

Contest awards will be issued in each operator class in each of the continental 48 US states, Canadian provinces and territories, and each DX country represented. A minimum of 5 hours and 50 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms or to submit an entry, forward an SASE to: 40-Meter Contest, Billy E. Maddox, 468 Century Vista Drive, Arnold MD 21012.

2ND ANNUAL 80-METER WORLD SSB CHAMPIONSHIP

Starts: 0000Z January 9
Ends: 2400Z January 9

SPONSOR:

73, Peterborough, New Hampshire 03458.

MISCELLANEOUS RULES:

Work as many stations as possible on 80-meter phone during the specified times of allowable operation. The same station may be worked once. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All the multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your log(s) and on your summary sheet. Off periods are no less than 30 minutes each.

OPERATOR CLASSES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental 48 US states and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

1 QSO point is earned for each station worked in the continental 48 US states and Canada or within' your own country. All other contacts are two points each. List points for each contact on your logsheet.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum), each Canadian province or territory (13 maximum), or DX country worked.

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include a contest log, a contest summary, and multiplier checklist. We recommend that contestants send for a copy of the contest forms. Send an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 12, 1983.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

AWARDS:

Contest awards will be issued in each operator class in each of the continental 48 US states, Canadian provinces and territories, and each DX country represented. A minimum of 5 hours and 50 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms or to submit an entry, forward an SASE to: 80-Meter Contest, Billy E. Maddox, 468 Century Vista Drive, Arnold MD 21012.

2ND ANNUAL 160-METER WORLD SSB CHAMPIONSHIP

Starts: 0000Z January 15
Ends: 2400Z January 16

SPONSOR:

73, Peterborough, New Hampshire 03458.

OBJECT:

To work as many stations as possible on 160-meter phone in a maximum of 30 hours allowable contest time. Multi-operator stations may work the entire 48-hour contest period. Stations may be worked only once.

ENTRY CATEGORIES:

(1) Single operator, single transmitter, phone only. (2) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental US and Canada transmit an RS report and state, province, or territory. All other stations, transmit RS report and DX country.

POINTS:

All valid two-way contacts score five (5) QSO points each.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum), each Canadian province or territory (13 maximum), and DX country outside the continental 48 US states and Canada.

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include logsheets, dupesheet for 100 or more contacts, a contest summary sheet, and a multiplier checksheet.

ENTRY DEADLINE:

Each entry must be *postmarked* no later than February 19, 1983.

DX WINDOW:

Stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed by top band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band. During the contest all stations are requested to utilize those frequencies from 1.808-1.825 and 1.830-1.900 MHz.

DISQUALIFICATIONS:

Operator omits a required entry form, operates in excess of legal power authorized for his/her given area, manipulates operating times to achieve a score advantage, or fails to omit duplicate contacts which reduce the overall score more than 2%.

AWARDS:

Contest awards will be issued in each entry category in each of the continental US states, each Canadian province and territory, and each DX country represented. A minimum of 5 hours and 50 QSOs must be worked to qualify.

CONTEST ADDRESS:

To obtain entry forms or to submit a contest entry, forward an SASE to: 160-Meter Contest, Billy E. Maddox, 468 Century Vista Drive, Arnold MD 21012.

2ND ANNUAL RTTY WORLD CHAMPIONSHIP CONTEST

Starts: 0000Z February 26
Ends: 2400Z February 26

SPONSORS:

73 and *The RTTY Journal.*

MISCELLANEOUS RULES:

The same station may be worked once on each band. Crossmode contacts do not count. Single-operator stations may work 18 hours maximum, while the multi-operator stations may operate the entire 24-hour period. Off periods are no less than 30 minutes each and must be noted in your log(s).

OPERATOR CLASSES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

ENTRY CATEGORIES:

(A) Single band. (B) Allband, 10-80 meters.

EXCHANGE:

Stations within the continental 48 US states and Canada must transmit an RST report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RST report and consecutive contact number.

QSO POINTS:

1 QSO point is earned for each valid contact.

MULTIPLIER POINTS:

1 multiplier point is awarded for each of the 48 continental US states, Canadian provinces or territories, and DX countries worked on each band.

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Entries must include a separate log for each band, a dupesheet, a summary sheet, a multiplier checklist, and a list of equipment used. Contestants are asked to send an SASE to the contest address for official forms.

ENTRY DEADLINE:

All entries must be postmarked no later than March 26, 1983.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

AWARDS:

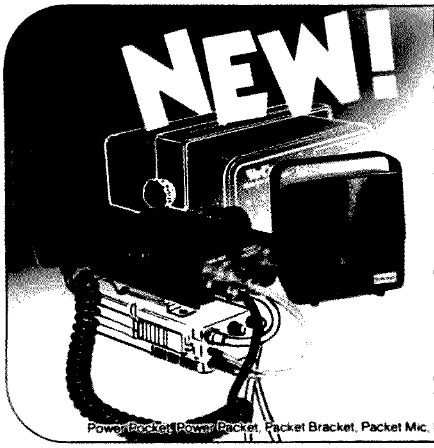
Contest awards will be issued in each entry category and operator class in each of the US call districts and Canadian provinces and territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 5 hours and 25 QSOs must be worked to be eligible for awards.

CONTEST ADDRESS:

Send an SASE to RTTY World Championship Contest, c/o *The RTTY Journal*, PO Box RY, Cardiff CA 92007.

WORLD COMMUNICATION YEAR

Next month's World Communication Year amateur radio activity will be using the 75 ITU zones for scoring multipliers. Be sure you use the correct ITU zones and not the ARRL zones for this contest. Copies of a world map and prefix list showing the ITU zones can be obtained from the contest sponsors, the Potomac Valley Radio Club, by sending an SASE or an IRC to: PVRC, PO Box 337, Cromsville MD 21032. Complete rules will appear here in my January column.



Introducing the POWER PACKET™ from VoCom

An innovative new product that you can combine with your VoCom Power Amplifier to obtain the functions of the famous VoCom Power Pocket™ *using any handheld radio.*

AF POWER — 2 to 3 watts of road-noise-overcoming audio to your vehicle speaker or to external Packet Speaker™ (optional).

EASY HOOK-UP — Packet Bracket™ at bottom of Power Packet, provides place to clip almost any make or model handheld. Connects to handheld through pin jacks. Hooded light on Power Packet illuminates portable's front panel.

CHARGE POWER — 35 mA charge on receive, 400 mA when mic is keyed. Unless your handheld draws more than 400 mA, you can talk as long as you wish and the batteries will be at least as charged as when you started.

MIC PREAMP — adjustable; tie in your handheld directly without changing its mic input. Also makes Power Packet compatible with most standard mobile mics. Optional Packet Mic™ available.

Suggested retail $84.95. See your favorite amateur radio dealer.

MICROWAVE AND SATELLITE TELEVISION

The standard RP downconverter package shown below gives you a proven 2150 Mhz downconverter mounted in a weathertight antenna that features low wind loading and easy installation.

All downconverters use microstrip construction for long and reliable operation. A low noise microwave preamplifier is used for pulling in weak signals. The downconverters also include a broad-band output amplifier matched to 75 ohms. The RP model is recommended for up to 15 miles. Over the range of 15 to 25 miles the RP+ which has a lower noise and higher gain RF amplifier stage, provides better television reception. For installations over 25 miles, an RPC unit which uses a separate antenna is available. All models are transient voltage protected by surge protection on both the power supply and the converter inputs. All models are warranted for one year.

The DCI 466 is a completely self-contained **IMAGE REJECTION DOWN CONVERTER** that is used for TVRO downconversion at the Satellite antenna where optimum signal to noise ratio can be obtained. The DCI 466 converts the TVRO band to 70 Mhz. The unit's DC power and a 17 to 25 volt local oscillator tuning voltage are superimposed on a single RG 59 line for easy installation. The unit has an on board IF amplifier matched to 75 ohms that gives plenty of drive for long cable runs. The overall conversion gain is 25db. Image rejection is a minimum of 14db. $300 in singles.

Write for details on our low priced model VCO 40 voltage controlled oscillators in the four pin TO-8 package that cover the TVRO band. Also check our 120 degree low noise amplifier for low cost satellite ground stations.

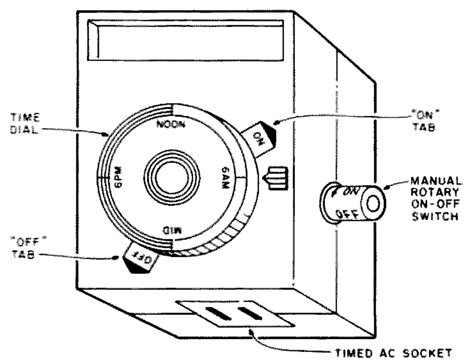
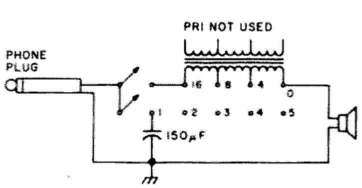
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

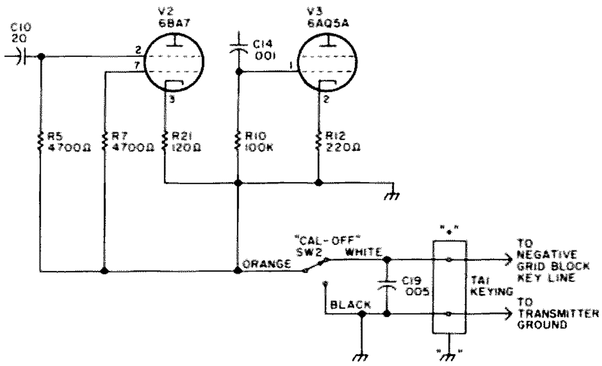
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



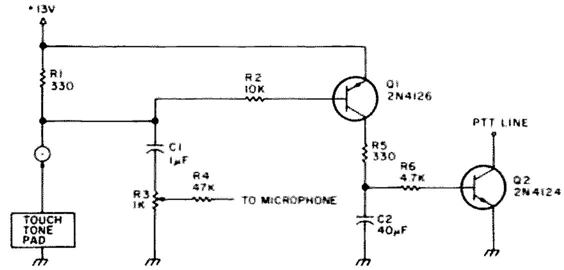
OVERTIME PROTECTION FOR NICADS: Nicad batteries are prone to damage if the batteries are charged for more than 12 to 16 hours. Unfortunately, most timers don't have a timer. To protect your batteries from possible overcharge and venting, you can add an outboard timer and thus protect your batteries. 24-hour appliance timers are available for less than $10. The timers have sliding "on" and "off" tabs which trip a switch when the dial rotates. There is also a rotary-type override switch on the back or side of the unit. To use this timer for your nicad charger, first disassemble the timer. Remove the tab from the "on" switch. To use the modified timer, set the dial to noon and set the "off" switch to a time 16 hours later. This would be 4:00 am. Plug in the charger to the timer, and turn the timer on with the manual override switch. If you have to interrupt the charging cycle and move the unit into another location, your unit will have a "memory" and the charging cycle will resume at the same time when you reconnect the unit.—John F. Sehring WB2EQG, Oradell NJ.



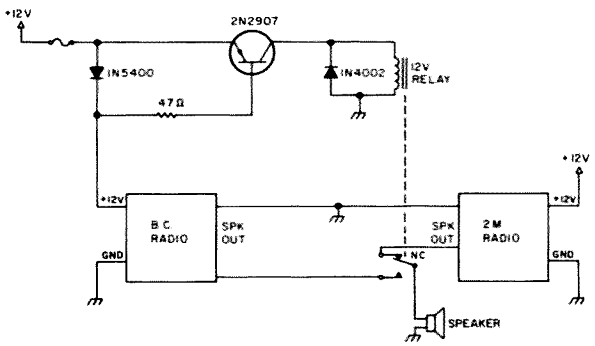
SIMPLE FILTER SPEAKER: There is nothing magical about this circuit. It consists of a universal output transformer which is secondary-tapped at 4, 8, and 16 Ohms, a 150-uF paper capacitor, and a two-deck five-position rotary switch to select combinations as shown. The clockwise position goes straight through to the speaker and each step to the left cuts more high frequencies in the manner of a typical tone control on a broadcast receiver. There is some attenuation of the overall signal (chiefly above the male voice range), so you can reduce the heterodynes from Radio Moscow and the adjacent channel sideband QRM to a tolerable level. You could use a transformer with more taps or more than one capacitor if that is what your junk box offers.—W. B. Cameron WA4UZM, Tampa FL.



HALLICRAFTERS HA-5 GRID-BLOCK KEYING CONVERSION: The Hallicrafters HA-5 vfo is cathode-keyed. This conversion will enable the rig to be grid-block-keyed with a minimum of surgery to the unit. Begin by disconnecting cathode resistors R12 and R21 from the orange lead of the "Cal-Off" switch, grounding them to chassis. Open R22 at the TA1 keying terminal strip. Disconnect R5, R7, and R10 from chassis, and connect their junction to the orange lead of the "Cal-Off" switch. To reconvert to cathode keying, disconnect the ungrounded ends of R5, R7, R10, and R22, leaving them bent out, while installing new R5, R7, and R10 resistors whose long leads will more readily reach to the orange "Cal-Off" switch lead. The grid-block transmitter lead (negative) then connects to the terminal marked "+", and the transmitter ground connects to the terminal marked "ground" on the vfo keying terminal strip.—Tuckerman S. Jalet AA1C, Stamford CT.



TOUCHTONE™ TECHNIQUES: This circuit allows for one-hand operation of any surplus-type touchtone pad. Q1 and Q2 form a high-low switching circuit controlled by R1. When any key is depressed, Q1 will conduct, applying 12 volts to the pad. Then Q2 conducts, keying the transmitter. After you have completed dialing, the keying circuit returns to the "rest" mode and the transmitter must be keyed by the PTT. Delay time is controlled through selection of C2 and R6. Component values are not critical.—Joseph A. Taylor W9JO, Green Bay WI and Hugh Kelley WB9NON, Rhinelander WI.



SUPER AUTOMATIC SPEAKER SWITCH: This circuit will switch a speaker between your broadcast radio and your two-meter rig, depending on which radio is turned on at the time.—Halm Sandel KB2IV, Flanders NJ.

1982 INDEX

HAM HELP

I need a manual or a copy of it for the Globe Scout model 680-A. I will gladly pay all costs.

Dennis Cornell
7835 Captain St.
Millington TN 38053

I am looking for the following: MK 731/ARC-51X, H-157/AIC, H-158/AIC, ME-57/U, USM 281E, ME-11/U, URM-120, URM-127, O-1131/GRC, URM-103, AN/AIC-25, PRC-49, PRC-90, URC-10, ARA-50, SRD-7, URD-4, OA-3633/ORC, R442/VRC, RT524/VRC, PRC-74B, RT-662/GRC, R1051/VRR, 61BT, ARC-159. I also need modules for the following: ARC-58, SG-179A, AM1528B/URC, CV465C/URC, RE-284/URC, 0-655/URC, MC-286B/URC, KY-305/URC, CV-466A/URC, CV-987/GRC-110A, AM1525/URC, AM-476C/AIC-10 unpotted, CU786/TRC-75, CU749/TRC-75, C2848/TRC-75, URM-124, MK-500/U, 878L-3, GRM-21, GRM-10, CU-523/ARC-58, C-1939/ARC-58, R1149/ARC-58(v), C-1940/ARC-58, R-1283/GRC, R484/APR-14, APR-13, URT-23(v), AM-1780/VRC, H-250/U, RT834/GRC, R1123/ARC-73, C-4074/RC-73, C-3940/ARC-94, URM-205, VRM-1, and USM-223. I am also seeking any documentation on the ARC-58, TRC-75, and ARC-159, and I would like to hear from anyone using the TRC-75.

Leroy Ritta
PO Box 102
St. Marys 5042
South Australia
Australia

I need the 20-meter heterodyne oscillator coil (part no. 40-771) for my Heath SB-301 receiver.

George Savino KV2V
388 N. Monroe Ave.
Lindenhurst NY 11757

I would like a schematic for an Allied Star Roamer receiver, number 22-3993-710042-713.

Joe Hustak WA5ZNO
6821 NW 27th St.
Bethany OK 73008

I am in need of videotapes (VHS format) of Novice- and General-class theory material. I also need good audio tapes for mastering Morse Code.

Robert M. Gallery
9214 Weathervane Place
Gaithersburg MD 20879

I need a 3CV1500 tube for my Alpha Vapor amplifier.

David Ornee KA9JKQ
4615 Howard Ave.
Western Springs IL 60558

I need help correcting a severe drift problem in the lmo/vfo of my Heath SB-102. Anyone with information on this problem or who can fix it, please write.

Harold Wright K4MFN
Rt. 1 Box 259
Chancellor AL 36316

I am trying to find a 3-inch picture tube, type C6407, for a Symphonic model TPS-30 television. I would also be interested in buying the entire set if the picture tube is good.

Al Duester
179 Woods Hole Rd.
Falmouth MA 02540

I am badly in need of the manual or schematic for Navy surplus receiver R808/GRC-14, a unit of radio set AN/GRC14.

Lee A. Grunewald K5JGZ
1020 K St. NW
Miami OK 74354

I need the construction manual and schematic for a Dycomm 2-meter linear amplifier. I will pay for the original or copying costs and postage.

Marvin Rosen N3BOA
20 W. Madison St.
Baltimore MD 21201

Wanted: 40-kV, 0-200-pF vacuum variable capacitor.

Cliff Young WA2TGY
PO Box 790
Parker CO 80134

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

LMRE AWARDS

Here are the details of an awards program recently instituted by the Liga Mexicana de Radioexperimentadores (LMRE) and open to all amateurs anywhere; there are currently four awards offered.

6Z6 Award

Available for confirmed contact with any 6 Mexican stations after January 1, 1980.

American Award

Requires confirmed contact with 40 countries in the Western hemisphere (ARRL DXCC list) plus 10 contacts with XE stations.

Mexico Award

Requires confirmed contacts with 20 stations in Mexico.

Worked All XE (WAXE)

Requires 25 confirmed contacts, 15 with XE1, 5 with XE2, and 5 with XE3 stations.

Awards cost US $3.00 or 10 IRCs each and require that either the QSL cards or a list certified by the awards secretary of the local league be submitted to the LMRE of Mexico City. If QSL cards are submitted, be sure to include sufficient funds for return of same via international registered air mail. The address for applications is: LMRE Awards Manager, c/o Manuel De Lera, PO Box 907, Mexico 1, DF, Mexico.

JOLIET AMATEUR RADIO SOCIETY

The Joliet Amateur Radio Society is sponsoring the JARS award. Illinois stations must contact 10 JARS members. Continental US stations must contact 5 JARS members. No repeater contacts. An updated membership list is available on request for an SASE or 2 IRCs. Send list of log information and $1.00 (DX station may send 3 IRCs) for the award to: Paula Franke WB9TBU, Certificate Chairman, PO Box 873, Beecher IL 60401.

THE IOWA AWARD

An award will be issued to any amateur who has worked 19 Iowa counties. Cost will be $1.00. Each additional 20 counties will earn a new award. QSLs not required. Send usual log information and statement by two other amateurs or one club officer to the Mississippi Valley Radio Club, 3518 Columbia, Davenport IA 52804.

THE PLANET EARTH AWARD

The South West Ohio Repeater Club (SWORC) takes great pleasure in presenting the Planet Earth Award. To qualify, applicants must submit proof of QSOs with 10 different stations on the planet Earth. There are no restrictions, but QRP operations will be noted. Send your list of contacts along with the award fee of $4.00 or 12 IRCs with an SASE to the Awards Chairman, South West Ohio Repeater Club, PO Box 18005, Cincinnati OH 45218.

WORKED ALL MORTON AWARD

The Morton Amateur Radio Club has announced its new award program. The Worked All Morton award is issued to those hams who have had QSOs with five members of the Morton Amateur Radio Club, or hams living in Morton, Illinois. Only contacts made on or after January 1, 1981, will count. To receive the award, applicants should send log information listing at least five Morton contacts along with a large SASE to Morton Amateur Radio Club, 701 Columbus Avenue, Morton IL 61550.

The club operated a special events station, W9EEB, during the Annual Morton Pumpkin Festival. An attractive certificate for the Pumpkin Award will be sent to all who QSL. The operation was held September 16 through 18, 1981, on 7.280, 14.280, 21.380, and 28.680 MHz. The award will be issued on receipt of QSL and a large SASE by W9EEB, 701 Columbus Avenue, Morton IL 61550.

In an effort to restore good operating practices to the amateur bands, a group of Morton Amateur Radio Club members have undertaken the sponsorship of the All American Alligator Award. This probably least-coveted certificate will be issued to those stations which exhibit acts inconsistent with the spirit or laws of amateur radio. We hope the award will be received in the same spirit with which it is being issued.

TEN-METER FM AWARDS

Sponsored by the North Whidbey Island Repeater Association (NWIRA), all contacts must be made on or after January 1, 1981. Crossmode contacts do not count. Contacts must be two-way ten-meter FM. Special endorsements include All-Mobile, All-Simplex, Single-Frequency accomplishments, and contacts made within a single day, week, month, or year. *Do not* send QSL cards; forward your list of contacts showing the date, time, and frequency of each QSO and provide a brief station description. Send with the fee of US $4.00 for each award to the attention of: Ten-Meter FM Awards Program, 2665 North Busby Road, Oak Harbor WA 98277.

Worked All Districts

To qualify, applicants must work one ten-meter FM station in each of the ten US call districts.

Worked All States

Applicants must work a minimum of 50 US states on ten-meter FM.

Centurion

This award requires the applicant to work a minimum of 100 stations on ten-meter FM.

DX Decade

Applicants must work a minimum of ten DX stations outside the fifty US states and Canada on ten-meter FM.

North American

To qualify, applicants must work all ten US call districts, a minimum of six Canadian provinces and/or territories, and at least four DX countries within the North American continent (other than the US and Canada) on ten-meter FM.

OTHER AWARDS

3rd Call District Maryland

Worked all Bowie ARC in two classes. First figure US stations, second, DX stations: class 1 = 4/2; class 2 = 2/1. Log data, SASE. No charge. To: John Rouse KA3DBN, PO Box Drawer M, Bowie MD 20715.

4th Call District Florida

Florida Skip Certificate of Merit issued on recommendation of two other amateurs for outstanding service. $1.00. Send to: Florida Skip, Box 501, Miami FL 33166.

XYL Award by Florida Skip

Only requirement is to render aid and comfort to your husband in and out of the shack. $1.00 or 4 IRCs to: Elizabeth Clark W4GGQ, 41 Lenape Drive, Miami FL 33166.

Three Thousand DX Award

North Florida ARS. Work three or more stations 3,000 miles or more distant, rag-chew-type QSOs only. Two certificates will be awarded, one to you and one to the DX stations. $2.00 to: Dale Mann N4AWI, 5433 Glorianne Circle North, Jacksonville FL 32207.

Worked Broward County Cities

Broward ARC. Stations in the Florida counties of Broward, Colliers, Dade, Glades, Henry, Lee, Martin, Monroe, or Palm Beach must work all 29 cities; others, 15. Work mobiles in Broward county. No awards for your mobile. GCR, US $1.00; DX, 10 IRCs, to: WD4RAF, 1921 NW 41st Street, Oakland Park FL 33309.

6th Call District

CHC Worked All Counties California. Issued in five classes: Class D = 20 to 28; class C = 30 to 38; class B = 40 to 48; class A = 48 to 57; class AA = 58; GCR, SWL, $3.00 endorsements, $1.00 to: Scott Douglas KB7SB, PO Box 46032, Los Angeles CA 90046.

7th Call District

CHC awards, to: Scott Douglas KB7SB, PO Box 46032, Los Angeles CA 90046.

Washington State Counties Award. Issued in five classes: Class D = 10 to 15 counties; class C = 15 to 20; class B = 20 to 30; class A = 30 to 43; class AA = 44.

Oregon State Counties Award. Issued in four classes: Class C = 10 to 15 counties; class B = 20 to 25; class A = 30 to 35; class AA = 36.

Nevada State Counties Award. Issued in three classes: Class C = 8 to 10 counties; class B = 10 to 15; class A = 15 to 17.

Utah State Counties Award. Issued in three classes: Class C = 7 to 10 counties; class B = 18 to 24; class A = 22 to 29.

Wyoming State Counties Award. Issued in three classes: Class C = 7 to 10 counties; class B = 15 to 20; class A = 20 to 23.

Idaho State Counties Award. Issued in four classes: Class C = 15 to 20 counties; class B = 20 to 30; class A = 30 to 43; class AA = 44.

Montana State Award. Issued in five classes: Class D = 15 to 20 counties; class C = 20 to 30; class B = 30 to 40; class A = 40 to 55; class AA = 56.

GCR, SWL, $3.00; endorsement, $1.00.

Morocco

CN8 Award by AREM. Work 15 CN8 stations on 1 band, 12 stations on 2 bands, or 8 stations on 3 bands. GCR and 3 IRCs to AREM, PO Box 2060, Casablanca, Morocco.

Diploma De La Ville Rabat by Assoc. Royale Des Radio Amateurs De Maroc, c/o CN8OB, PO Box 299, Rabat, Morocco. Work 10 stations in Rabat after January 1, 1968. All others, 5. SWL 10 IRCs, list.

India

Worked Republic of India, by ARSI, Box 534, New Delhi, India. Contact 50 different VU stations after January 16, 1950. QSLs, list, 12 IRCs.

The Gateway of India Award, by ARS of India, Western Zone. Work VUs in the Western Zone after November 9, 1957. Asia stations work 10; others, 5. GCR, 6 IRCs. To: Dady Major VU2MD, 85 Sleater Road, Petit Mansion, Bombay 7, India.

Lebanon

By Lebanese RAA, PO Box 1217, Beirut, Lebanon. Work 10 stations after July 1, 1958; with endorsement seals additional 10. No charge, GCR.

Spain

Spanish Diploma, by URE, Apartado De Correos, Num 220, Madrid, Spain. QSLs from 125 Spanish stations on CW with 60 on 3.5 or 7 MHz, 10 on 28, 15 on 21, and 10 on 14 MHz. After January 1, 1952. Send 40 QSLs, list, and return postage.

125 EA Award: By URE, Hortaleza 2, Apartado 220, Madrid, Spain. Work 125 EA stations after January 1, 1952, including all Spanish call areas. At least three contacts must be made with each (EA1 through EAØ) counting EA9 and EAØ as one area. QSLs, list, and return postage.

Romania

"YO-AD" All Districts Award. Work YO districts as follows: First figure is the number of districts to be worked, second is the number of QSOs per district. Applicants in zones 15, 16, 20: class I = 8/10; class II = 6/6; class III = 3/3. Applicants in zones 14, 17, 21, 33, 34: class I = 8/6; class II = 6/4; class III = 3/2. Applicants in all other zones: class I = 8/3; class II = 6/2; class III = 3/1. 144 MHz: class I = 4/1; class II = 3/1; class III = 2/1. There are 8 YO districts in all.

Canary Island

Work EA8 stations after April 4, 1971. QSLs, SWL, 10 IRCs to: URE, PO Box 860, Las Palmas, Canary Islands, Spain. EA and LX stations work 30, rest of EU, Central and South America work 20, North America and Africa work 10. Asia, Oceania, VHF and UHF, work 5.

Austria

WAOE Diploma. Work OE districts all CW, all phone, or mixed after January 4, 1954. Austria and adjoining countries work three stations each in OE districts 1 through 9 (with OE4 and OE9 counting as one district) using at least two different bands. At least one contact per OE district must have been made on 40 or 80 meters. Rest of EU stations: Same as above but without 40- or 80-meter requirements. GCR stations outside EU. Work one OE station in each OE district on any band (8 QSLs). GCR. Same station may be worked on all bands. WAOE SWLs for 8 districts. Send list and 10 IRCs.

Colombia

100 HK3 Award: by LCRA. Third HK zone. Coordinator for contacts with 100 HK stations after January 1, 1960. SWLs, no charge, GCR, list in alphabetical order and send full log data to: HK3VV, AP 584, Bogota, Colombia.

Double Call Award: Work HK stations with double- or triple-letter calls. Three

classes: Class C = 10, class B = 20, class A = all 26 double calls (AA to ZZ); AAA counts in lieu of AA, BBB for BB, etc. Contacts after January 1, 1960. No charge, GCR, log data to: HK3VV, AP 584, Bogota, Colombia.

CHK Award: by LCRA. Work HK stations. HK stations work 100 other HK stations, stations in Americas work 50, others work 25. HKs send QSLs, others send certified list authenticated by club official. QSLs must have been sent and received. To: LCRA, AP 584, Bogota, Colombia.

ZHK Award: by LCRA. Confirmed contacts with HK zones. HKs send QSLs from all 10 zones. Americas work 9, rest of the world work 8. All except HKs send list certified by club official. To: LCRA, AP 584, Bogota, Colombia.

(No charges given for any of the LCRA awards.)

HK7 Award: by RC Santander, PO Box 222, Bucaramanga, Colombia. Work 7 HK stations, either all CW or all phone, after January 1, 1962.

10 HK1 Award: by RC Del Atlantico, Apartado Nacional 184, Barranquilla, Colombia. Work 10 HK1 stations post World War II. GRC—certified by club officer. (No costs given.)

HK5 Award: by LCRA. Work HK5 stations after January 1, 1957. American countries work 12, Colombian stations work 20, rest of the world work 8. GCR list to: Box 6149, Cali, Colombia.

US Navy Award

Work 5 US Navy ships. To: Office of Naval Communications, Director, Navy MARS (OP945N), The Pentagon, Washington 25 DC 20301.

Radioman Submarine Award: Work 2 amateur radio stations on board submarines of Submarine Squadron Twelve plus club station W4YVS or any station on board the *Bushnell*. After January 1, 1961. Notarized log information with statement that the information is true and accurate to: Radio Amateur Club, Submarine Squadron 12, Naval Station, Key West FL 33040.

ARGONNE ARC

The Argonne Amatuer Radio Club plans to operate the club's memorial station, W9QVE, to commemorate the 40th anniversary of the first controlled nuclear chain reaction experiment conducted at the Alonzo Stagg field on the University of Chicago campus. Two stations will operate from 1500 GMT December 4 through 2400 GMT December 5.

Frequencies: phone and CW—20 kHz up from lower edges of the General portions of the 80-10m bands; Novice—40 kHz up; 2m—145.19/144.59, 146.52, and 147.42; RTTY—14.090 and 146.70. Send a business-type SASE or $1.00 for an 8" × 11" unfolded certificate to AARC, PO Box 275, Argonne IL 60439.

BETHLEHEM WV EXPEDITION

The Triple States Radio Amateur Club will operate daily from Bethlehem, West Virginia, December 9 through December 12, from 1400 to 2300 UTC. Operating frequencies for WD8DDL/8 will be 7.275, 14.325, 21.425, and 28.550 MHz on SSB, and 7.110, 14.075, 21.110, and 28.110 MHz on CW. A special holiday certificate will be sent to all those contacted who send an SASE to TSRAC, 26 Maple Lane, Bethlehem, Wheeling WV 26003.

CHRISTMAS VILLAGE

The K1BCI C/Q Radio Club will operate a special event station honoring the 35th anniversary of the Christmas Village located in Torrington, Connecticut. The club will operate from the Christmas Village from December 11 through 19, 1982, on 10, 15, 20, 40, and 80 meters. Certificates of this event will be issued for contacts made. For further information, contact Jim WA1YZA or Nellie WB1DVC.

SANTA CLAUS

The Pike County Amateur Radio Club of Winslow, Indiana, will operate a special events station from Santa Claus, Indiana, from 1700Z December 18 through 1700Z December 19, 1982. The callsign will be W9CZH. Operating frequencies will be (plus or minus QRM) 21.395, 14.305, 7.265, 3.925 phone, 7.133 CW, 14.093 RTTY, and 146.52 FM. Certificate for QSL and SASE to Santa Claus, PO Box 111, Ireland IN 47545.

CHESTER GREENWOOD DAY

The Sandy River ARC will operate KA1CNG on Saturday, December 18th, 1500Z, to Sunday, December 19th, 2100Z, in celebration of Chester Greenwood (inventor of the earmuff) Day. We will also operate mobile from the Chester Greenwood Day Parade and related activities on Tuesday, December 21st, 1400Z to 2100Z. Frequencies: 5 to 10 kHz from bottom of General band edges and 3940 kHz. Certificate for your QSL card and two first-class stamps (no envelopes please) to KA1CNG, 5 Franklin Ave., Farmington ME 04938.

HONG KONG ACTIVITY

The Hong Kong Amateur Radio Transmitting Society (HARTS) is pleased to announce that once again there will be a VS6 activity day between 0001G Saturday, April 2, 1983, and 2359G Sunday, April 3, 1983. As in previous years, many VS6 stations will be active on all bands/modes.

1983 is World Communications Year (WCY), and during 1983 the special callsign VS6WCY will be in use by the HARTS club station. Special QSL cards will be issued for QSOs with VS6WCY. QSLs for WCY station should be sent to the Hong Kong QSL Bureau Manager, PO Box 541, Hong Kong.

WORKED ALL NORTH POLE

The Borealis ARC will present, upon receipt of the request with the callsigns and dates worked of a minimum of three BARC members and $2.00, a Worked All North Pole certificate. Operating time will be from approximately 0400-0900Z, 30 kHz up from the lower edge of the Novice and General bands, plus or minus QRM. The club member whose callsign appears on the largest number of certificate requests during the month of December will win a prize. Certificate requests should be sent to: Borealis ARC, c/o Wendall Keller, SR Box 80343, Fairbanks AK 99701.

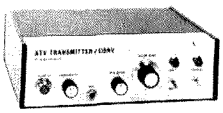
ATV TRANSMITTER/CONVERTER



TC—1

- **10 Watts Output**
- **Standard Frequencies Available**
- **Broadcast Standard Sound**
- **High-resolution & color video**
- **Regulated AC Supply Built In**
- **Tuneable Downconverter & Preamp**

Connect to the antenna terminals of any TV set, add a good 450 MHz antenna, a camera and there you are. . . Show the shack, home movies, computer games, video tapes, etc.

ATV DOWNCONVERTER

For those who want to see the ATV action before they commit to a complete station, the TVC-4 is for you. Great for public service setups, demos, and getting a buddy interested. Just add an antenna and a TV set tuned to CH. 2, 3, or 4 and plug in to 117 volts a.c. **$89.00**

TVC-4

TVC-4L extra low-noise version. . . $105 delivered in USA

HOMEBREWERS: ASK FOR OUR BASIC FOUR-MODULE PACKAGE

CALL OR WRITE FOR OUR COMPLETE LIST OF SPECIFICATIONS, station setup diagrams, and optional accessories which include antennas, modulators, detectors, test generators, cameras, etc. WE ARE A FULL-LINE SUPPLIER OF ALL YOUR ATV NEEDS.

TERMS: VISA or MASTER CARD by telephone or mail, or check or money order by mail. All prices are delivered in USA. Allow three weeks after order for delivery.

THE TEN-METER BAND

Many DXers abandon the 10-meter band as sunspot numbers fall. But 10 meters provides DX excitement even at the bottom of the sunspot cycle. Not as much, to be sure, as when 10 is wide open to three continents at once, but, still, there is plenty of action. Because 10 meters lies at the dividing line between HF and VHF, it displays some of the propagation features of each part of the spectrum. By learning to recognize the different modes of propagation and practicing the operating patterns unique to each propagation mode, the DXer can quickly improve his success on 10 meters. The second weekend of the month of December provides a fine opportunity to practice this skill, in the ARRL 10-Meter Contest.

Let's look at the various ways DX signals get from here to there, and how the DXer should modify his operating techniques to take full advantage of each propagation mode.

HF Spectrum

Most DX contacts are made via the F2 ionization layer of the ionosphere. The F2 layer is ionized by radiation from the sun and tends to be strongest near the middle of the day. Thus, 10 meters will open up to the east in the morning. As the Earth turns, the band opens farther south, and then it swings around to the west in the late afternoon. The DXer can recognize F2 propagation because it is so widespread, with signals from a large part of the world coming in all at once. This propagation mode is quite steady, building rather slowly and fading gradually. Normal DXing techniques will be successful: Aim your beam at the station and make your call.

Ten meters is not always "open" via F2 propagation. So some DXers will quickly tune across the band with the beam aimed east, hear nothing, and drop to 15 meters. However, even when the ionization is not strong enough to provide east-west propagation, it often is strong enough for north-south contacts. The equatorial region receives more solar radiation than latitudes farther north and often gets enough radiation to open the 10-meter band. Instead of the normal sequence of the band opening up in the east and swinging around to the west, around midday or a little later the band opens up just to the south.

WA1KID used to take advantage of this phenomenon during contests with a 4-element 10-meter beam fixed south. He could switch quickly to that antenna to watch for the trans-equatorial openings and nab the CEs, LUs, and other South Americans. The only trick to working DX via trans-equatorial propagation is to know when and where to look; if your beam is aimed east, for example, you might never hear the South Americans.

This same ionization over the equatorial regions provides one of the more interesting propagation modes on 10 meters: back scatter. Strong signals aimed south can reflect off the ionization layer over the equator and bounce down to earth, and some small portion of the signal then bounces back along the same path. Not much of a signal gets through, to be sure, since most of the energy is lost or absorbed in the multiple bounces, but directional signals will be scattered enough by the ground at the other end of the hop to send some energy *back north*.

This means that it is possible to work other stations north of the equator by pointing your beam almost due south! Backscatter signals are very weak, so both stations must point their beams toward the ionization to the south. If you hear a European signal while your beam is aimed south but the signal fades as you swing your beam up to the northeast, you are probably receiving back- or side-scatter signals. You can recognize these signals because they are weak and peak to the south, no matter in what direction the station is located.

If you hear a scatter signal, resist the temptation to swing your beam according to the beam-heading chart; the signal will disappear. (If it gets louder, you're not hearing a scatter signal!) Instead, swing your beam across the south, listening for the loudest direction, the direction of the most intense ionization, and, therefore, the most scatter. Note that both stations must be beaming south. If the DX station hears your signal and swings his beam up to the west to work you, the contact is lost.

Explaining this under the weak signal strengths of scatter contacts can be frustrating. I remember spending 20 minutes once trying to convince a station that we could make contact only if *both* of us pointed our beams south and not at each other! Whenever this W4 heard my call from New England, he would swing his beam north and lose it.

Side scatter is very similar to back scatter. The radio waves reflect off the side of the ionization region, not the underside. Again, you swing your 10-meter beam back and forth, listening for the loudest signal without regard to the direction of the other station. If you can convince the DX station *to do the same thing, you can have a satisfying DX contact.*

VHF Spectrum

Since the 10-meter band is near the VHF region it exhibits some of the exciting propagation modes of VHF bands, including meteor scatter and E-skip. These short-range propagation modes don't often provide much DX, but it helps to learn how to recognize and operate under each mode.

Meteor scatter is radio propagation off the ionized trails left after a meteor rips through our upper atmosphere. Since the Ten-Meter Contest coincides with a major meteor shower, you might well hear such signals then. Meteor-scatter signals last *only a few seconds because the ionization* region quickly dissipates. Your contact must be very short; giving your call three times probably will use up the entire opening! Listen for randomly-occuring, quite loud signals which appear and disappear very quickly. If you start a contact on one meteor burst, you may well be able to complete the contact on another burst a minute of two later if you stay on the same frequency and beam heading. Don't expect to exchange much more than a signal report, however, as meteor-scatter QSOs are extremely short.

E-skip enlivens the 10-meter band quite often. The E ionization layer is much lower than the F layer, and the maximum communication distance on a single hop is about 1200 miles, compared to twice that with F2 propagation. But multiple-hop E-skip can provide some DX contacts, thus injecting some life into a "dead" band.

Because the ionization regions in the E *layer are much smaller* than those in the F layer, the E-skip propagation is much more restricted in area. You might hear only one or two states or countries at a time, for example. E-skip signals can be very loud as well as very directional, but often you can work stations around the fringes. Say you work a few G stations but don't hear anything else. Try a call for EI, GM, GD, etc. People are always listening, and a direct call can pull them out of the woodwork. E-skip propagation is notoriously fickle, appearing and disappearing rapidly. Don't be surprised if your contact fades away in midsentence.

OSL Card Errors

However your signal gets from here to there, you will probably want a QSL card to confirm the QSO. And you had better fill your card out properly if you expect a return QSL. Almost 25% of all QSLs I have received are not filled out properly, yet there are only a half-dozen pieces of information that need to be entered. And any QSL which is improperly filled out can delay the return QSL or even end up in the circular file! Let's look at the common mistakes and how to avoid them.

The callsign. A surprising number of QSLs arrive without the DX station's call in the appropriate place. If the callsign is anywhere but in the "confirming QSO with" or "radio station" box, the QSL is invalid for awards. Don't confuse the QSL manger's call with that of the DX station.

The date. Almost every country in the world except the United States uses the sequence day/month/year for the date. 12/2/82 is February 12, not December 2. To remove all ambiguity from the date, use Roman numerals for the month, or English abbreviations: 12II82 or 12 Feb. 82. Make sure you changed the date at 2400 UTC, which occurs in the middle of the evening before, local US time. I can't tell you how many cards arrive with the date one day off.

The time. There is no excuse for using anything but UTC on DX QSLs. Local time is for local QSOs only. And if you try to convert your local-time log to UTC for the QSL card, sooner or later you will make a mistake. Keep your log in UTC and keep a UTC clock in the shack. And keep your clock accurately set to WWV. A DX station or DXpedition operating "contest style" might fill a 50-entry log page in less than 10 minutes. If the time on your QSL is off by *more than 5 minutes, the QSLer might have* to search through several pages of logs for your contact.

Frequency. Be careful not to put the *band* in this box—"Frequency 20," for example. If you change bands often (during a contest, for example), watch your log. It is very easy to change bands to work a station and forget to log the band change. Then the card has the wrong band. I always prefer to receive a card with the exact frequency, such as, 14205. Since I log my exact transmitting frequency, this can help to find a QSO with the wrong date or time.

Mode. If your QSL has this box labeled "2X," just write in the mode. If the box is labeled "mode," write "2X CW" or "2X SSB."

RST. Honest signal reports in DX are as rare as Albanian contacts. I always prefer honest reports, but usually get 59 even if the other station can barely hear me.

QSL. Always ask for the QSL if you want it. I get thousands of cards which I may assume are requests for my card, but nowhere does the station specifically request my card. If things get a little behind, I may assume these cards are answers to cards I sent, and I don't answer them. And if you need a card for a particular reason, say so: "Need 3 more cards for my DXCC, please QSL," or "Please QSL for 5BDXCC."

Other things to remember: If you work a DX station during a contest with consecutive numbers as part of the exchange, write the *other station's* QSO number on the card: "your number 1024." Don't put your own number on the card, as the DX station could care less. His consecutive number will locate your contact quickly in a long log.

Speaking of contests, be sure to mention that the contact was made during a contest, if it was. Many stations keep separate logs for contest and non-contest operations because of the special logs that contests require. So include "CQ WW SSB contest," as appropriate.

Always send a card for *each* QSO. Although it is tempting to put all your contest QSOs with a single DX station on one card, it often will slow up your response. The DX station might QSL one band at a time or, as in the case of major DXpeditions, have separate managers for each band. Splurge, and send separate cards.

Finally, write legibly and accurately. Numerous QSLs have the information so badly written that it is almost impossible to read. Or the information is mis-copied from the log. These QSLs end up in the "do tomorrow" file or the circular one. And I still have cards from five years ago in my "do tomorrow" file. . .

And now a special treat for you loyal readers of this DX column. Send me your QSL card by the end of the year and I'll put them all in a hat and draw out three cards. The lucky winners will receive: a 1983 DX Callbook, a one-year subscription to *The DX Bulletin*, the most prestigious of the DX bulletins, or a one-year subscription to the W6GO QSL List, a list of more than 5000 QSL managers which is updated every two weeks (more about this prize next month)!

So send in your cards to the address at the head of this column, right away. No cost, no obligation; just mail me your QSL card and I'll notify the lucky winners immediately. Include a slide or black-and-white photo of your shack, and I'll use the best shots. Thanks for being such devoted readers of this column.

HAM HELP

Do you need help in getting your Atari computer on RTTY or ASCII? Drop me a line, and I'll be more than happy to get you started.

Bob Holsti K7ZJD/KH2

SATELLITES

Ariane Takes a Dive

The amateur radio space program suffered another setback on September 10. On that date, a European Space Agency (ESA) Ariane rocket fell into the Atlantic Ocean instead of achieving orbit as planned. It was the second failure in five launches for Ariane, the vehicle which was scheduled to carry the Phase IIIB amateur satellite aloft in early 1983.

This time, the Ariane carried no amateur birds, but two multi-million-dollar communications satellites on board were lost. Apparently, the rocket dove into the ocean when a third-stage fuel pump failed. If the problem turns out to be specific to the unit that failed and not a design flaw, the Phase III launch schedule may be only slightly affected and the amateur satellite could still be launched sometime this spring. Amateur satellite enthusiasts can only wait patiently for ESA to work out bugs.

Incidentally, the Ariane failure is a serious blow to ESA, which is in head-to-head competition with NASA and the Space Shuttle in the satellite launching business. With Ariane's success rate running only 60%, some ESA customers are getting edgy and may take another look at what the Shuttle has to offer.

MARECS: 0 for 2

One of the satellites lost in the ill-fated September launch was MARECS B, the second Maritime European Communications Satellite. What makes the loss particularly devastating is that the first bird in the series, MARECS A, failed in orbit without ever becoming operational. The bottom line is $250,000,000 spent without a single positive result for MARECS backers. Space flight remains an expensive business.

Thanks to *AMSAT Satellite Report*.—Jeff DeTray WB8BTH, *73* Staff.

HAM HELP

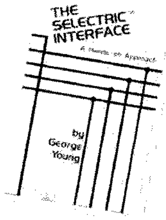
Wanted: a relay for the Heathkit HW-12 monoband transceiver. Please send price info on how I can get one. Thank you very much.

Rick Dill WA0EDH
3007 S. 44th St.
Lincoln NE 68506

I'm looking for a 40m QRP SSB transceiver for mobile use. If anyone has a 40m QRP rig or info on converting a CB to 40, I would appreciate it if they would contact me.

Roosevelt Hamilton WD4PSW
1112 Lownde Ave.
Pensacola FL 32507

THE SELECTRIC™ INTERFACE



Daisy wheel quality without daisy wheel expense.

You need the quality print that a daisy wheel printer provides but the thought of buying one makes your wallet wilt. *Selectric™ Interface*, a step-by-step guide to interfacing an IBM Selectric I/O Writer to your microcomputer, will give you that quality at a fraction of the price. George Young, co-author of *Microcomputing* magazine's popular "Kilobaud Klassroom" series, offers a low-cost alternative to buying a daisy wheel printer.

Selectric Interface includes:

- step-by-step instructions
- tips on purchasing a used Selectric
- information on various Selectric models, including the 2740, 2980, and Dura 1041
- driver software for Z80, 8080, and 6502 chips
- tips on interfacing techniques

With *Selectric Interface* and some background in electronics, you can have a high-quality, low-cost, letter-quality printer. Petals not included.

Credit card orders call TOLL-FREE 1-800-258-5473. Or mail your order with payment plus $1.50 shipping and handling to: Wayne Green Inc. Attn: Retail Book Sales, Peterborough, NH 03458.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

But this pursuit is a totally selfish one. There are no benefits to the hobby... to society. The world is not inched ahead one whit by these chaps. The League has let loose a monster on the world of amateur radio with their Honor Roll.

My own solution to this problem was to work hard and have fun as I worked toward 300 countries. Once I got to that level, I stopped counting. Today, when I hear a new one, I'll take a few minutes to get him in the log... preferring to talk with him if at all possible. If things are too frantic, I have better uses of my time... a lot better. I haven't the vaguest idea of how many countries I've worked and I don't intend to try to count 'em up. Perhaps, if the League would let newcomers to DXing get credit for countries worked up to 300... with no further listings after that... we might be able to put a stop to this thing.

Remember that working DX and getting up on the Honor Roll requires mainly that one be able to spend enormous amounts of time at it. This is not time spent in learning anything or in developing a skill of use to the world. Once you have a decent station, you can make a contact anywhere in the world, so it's just a question of sticking around, being there at the right time, and then bludgeoning your way through.

One of the supposed purposes of amateur radio is to help develop world friendships. Show me a hint that DX pileups and the badgering of ops in rare countries for instant contacts and a QSL generates anything but a disdain. Much of this is aimed at Americans, who are by far the worst in this regard, though at times I find the Germans pushing us hard for bad manners awards. Oddly enough, those hundreds of thousands of no-code Japanese hams are about the best-mannered operators in the whole world... and they have almost one million licensed amateurs today!

Those no-code hams, trained by their local ham clubs, often make *us* look like the CBers. They put most Americans to shame when it comes to real operating skills. And I don't think we can excuse our behavior on the air by explaining that learning the code made us crazy. I know that a lot of hams use the Morse Code as an excuse for being such terrible operators, but I don't believe that something that simple could explain what happens when a PYØ comes on the air.

And I don't think we can shrug our shoulders and put the whole thing down to basic cultural differences. The Japanese may bow when they meet, but they knock you around in the subways and in stores just as hard as you get bumped in America. No, the difference is, I believe, in basic ham training... in their club-trained hams. That's where they get across the concept of pride in being a ham and the responsibility of being a good operator.

Or, as old and good friend Bob Sullivan used to say, "I may not be wrong, but I'm not far from it."

SMALL HAMFEST CATASTROPHE

Some years ago, a disgruntled ham almost got the New England ARRL Convention closed down. The problem hinged around the breaking of federal laws having to do with the advertising of lotteries through the mail. You can't, yet most hamfests and conventions continue to do this, ignoring the federal laws they are breaking.

Please note that it is presently against the law for any hamfest or convention to send a brochure through the mail which promises prize drawings if there is a charge for attendance... and there always is. Further, it is illegal for any magazine or other publication which uses the mails to mention that prizes will be given where there is a charge for attendance.

If you want to give prizes, fine ... but it is illegal for you to mention that in anything which is going to be sent through the mails. You cannot send flyers or posters with this information on them through the mail. Got it?

No one has ever determined just how much prizes build up attendance at hamfests. As far as I know, every hamfest gives prizes, so no one *could* yet have tested the concept. With the veil of secrecy on prizes being lowered by the post office (*we* have heard from them in no uncertain terms), it may get a whole lot more difficult to get cooperation from manufacturers in the way of donated equipment.

Before the "incentive licensing" debacle of '63, it was much easier to get prizes. The ham industry was growing rapidly, meeting the needs for the then-new sideband equipment, so they were happy to donate nice prizes for our hamfests. Today, with only a handful of American firms left, most of the hamfest prizes have had to be bought, so the munificence has not been awesome. If hamfest committees decide to spend less on prizes, this would leave them

UNCLE WAYNE WANTS YOU!

When was the last time you wrote an article for *73*? Never??!! Then it is time you got started.

We are going to make 1983 the best year ever for fun, exciting articles in *73*. To do this, we'll need articles on many different topics. That's where you come in. Even if you've never written an article for us before, we want to hear from you.

What Do I Write About?

Ham radio is really about two dozen hobbies all rolled into one, so there is no shortage of interesting topics. Here are just a few:

- Antennas. Almost every ham experiments with antennas. Whether you've built a 2-meter yagi, an 80-meter quad, a helix for Phase III, or a multiband dipole, other hams can't wait to try your design. Tell 'em all about it in *73*.
- DX. Been on a DXpedition? We all enjoy reading about exotic people and places. Here's a chance to recount your adventure.
- Special Events. Hams get involved in some wacky and wonderful activities. Like Field Day from a floating raft or operating from hot air balloons. If it's worth a story, let us here from you.
- Reviews. New ham gear is released every week, so how does anyone know what to buy? You can help by writing reviews of your new equipment for other hams to read. Check with us first though; we don't want you to duplicate the efforts of someone else.
- Accessories and Gadgets. Home-brewing small projects is an amateur radio tradition. If your latest preamp, digital clock, or electronic sock warmer is a good performer, the rest of us want to hear about it.
- Major Projects. The design and construction of a transmitter, receiver, or power amplifier is a task requiring knowledge and skill. We want to publish the details so that other hams can enjoy the satisfaction of building a big project.
- Test Gear. Hams love to save money. That's why they'll be interested in your homemade test equipment. We'll have room for lots of transistor checkers, capacitance meters, logic probes, diode testers, and the like during 1983.
- Satellites. Whether it's OSCAR, RS, or TVRO, hams want to know more about building their own satellite gear. Downconverters, antennas—you name it and our fellow amateurs are eager for plans and information.
- Digital Communications. Microcomputers make RTTY neat and simple, but we can do so much more. If you are experimenting with higher baud rates, packet radio, new TU designs, coherent CW, or any of a host of other possibilities, you can tell the amateur world about it by writing articles for *73*.
- Computers. Microcomputers are fast becoming a fixture in many shacks. What are you doing with yours?

Those are just a few of the many ideas for articles. You'll think of more if you work at it.

What's In It for Me?

Cash. Unlike some ham magazines, *73* pays for the articles we publish. It may not buy you a new tower, but it might get you that new beam.

Prestige. Just imagine how impressed your friends and relatives (not to mention your boss) will be when they see your article published in an international magazine!

Enthusiasm. When you write for *73*, you help to generate the excitement that makes ham radio so much fun. Both simple and complex articles find an eager audience.

What to Do Next

For a full description of the nuts and bolts of article preparation, send for the *73* Author's Guide. If you can't wait that long, double space your manuscript, leave generous margins, carefully organize your diagrams and photos, and send the whole package to us. Our address is: *73*, Peterborough NH 03458.

Now, don't just sit there—*start writing!*

with some cash to invest in better speakers.

It's been my observation that hams will drive for hundreds of miles to hear someone interesting talk about their favorite subject. I don't know of anyone crazy enough to drive a couple hundred miles for 1/10,000th chance at an HT. You know, *you* can help. Hamfest committees really don't know who to ask to come talk at their shows. If you'd take the time to write a short review of any interesting talks you've attended at hamfests, this might get the word around.

The fact is that we do have a number of hams who get to fascinating DX spots and go through all kinds of remarkable hell in the process. Some of these chaps are most interesting, if we could only hear about it. Please take the time to pass the word to us here at *73* .. . and we'll get your material into the letters column as guidance to other hamfests.

The opposite side of the coin is that a few of our best known DXers are turkeys. It is most incredible how someone can go through some of the adventures these chaps have and be able to make it sound so incredibly dull to hear about. I once fell asleep at the dinner table trying to get anything of even the slightest interest out of two very well-known DXpeditioners.

There are plenty of interesting people around our hobby. Why not get one of our well-known ham publishers to tell about how he got his ham ticket in the '60s without knowing diddly squat about either the theory or the code? I'll bet we'd love to hear about his trip to northern Maine to get a "Conditional" license and his later trials with the FCC when they found out.

Then there is Jean Shepard K2ORS, with two successful PBS films to his credit and a third in production. Jean is by far the best humorist we have in the hobby and our hamfests should grab him when they can. I understand his latest film, "The Great American Fourth of July. . . and Other Disasters," is up for an award. If you do get him to speak, be sure to tape it and send me a copy. Shep isn't inexpensive to get, but he will pull 'em in. . . and be worth every dollar you spend.

No one really interesting is going to be cheap to get. That's the law of supply and demand. And, as Shep found out long ago, few people really appreciate anything they get for nothing.

My own experience has been that when I speak for free I often find a lack of support by the hamfest committee which results in two or three dozen in attendance. If I cost $1,000 plus all travel expenses (first class), you can bet they will be doing everything they can to get people to listen to me. Then I find myself facing two to three thousand in the audience instead of dozens. Between my already-made show commitments and trying to run my steadily-growing publishing firm while keeping up with two fast-growing industries, I'm not fishing for more work. If I do have extra time, it goes for writing, consulting, and even a touch of hamming. Most hamfests are on weekends, which is prime writing time.

In addition to getting interesting speakers for hamfests, with the no-longer-useful prize money, committees might look into putting on some really good demonstrations of new ham communications modes. I suspect that many amateurs would love to see some good slow-scan demonstrations. They'd also like to see fast-scan television. Then there is a growing interest in packet communications. But, for heaven's sake, watch out for some of the super turkey "experts" who flaunt their *doctor* titles. Several of these birds are crashing bores. Hamfest committees might, if they don't have personal recommendations on the "experts," ask for an audio tape preview and judge it as they might a radio audition.

If you have some hamfest committee members who are enthusiastic about the Morse code, why not try to inspire hams to accept code as a fun activity instead of merely something the government forces them to learn. . . and run code-copying contests, with certificates for the winners to display in their shacks. You can help bring some pride to knowing the code, something sadly lacking today. How can one have pride in something which is mandated by the government? Some of the prize money can go for awards for code skills. There's no lottery aspect to *that*.

You might get some of your more fanatic DXers to bring in their rare cards for a display. . . and for a talk on how to get the darned things. That is an art in itself. A big board for attendees to pin up their cards, with a QSL contest (also not a lottery, obviously), won't hurt.

I realize that bribery and greed are time-honored movers of people, but let's try to cope with the post office laws and find alternate ways of getting hams to come to hamfests.

THE GREAT AMERICAN HAM CLUB. . . DISASTER

When I see the Japanese ham magazine each month, with a whole section devoted to club activities. . . often with 70 or more pages of news about the clubs and pictures of their activities. . . I think of how little our clubs are doing. . . and reporting. I don't think we could generate that much news in a year, much less every month.

Even the best of our ham clubs seem to have their ups and downs. One thing that might help would be an updated series of articles on how to run a ham club. I did run such a series nearly twenty years ago and it was very well received. It's about time for an updated series, eh?

Running a ham club is show business, which many of us seem to forget. Many club presidents gather weak people around them to help make the club go. They do little to organize exciting meetings and often let business intrude on the fun . . . only to find that in a few months they have little left of the club.

I'd like to see some articles on how to make ham clubs succeed. I believe that the real strength of amateur radio lies in the strength of the clubs, not in a small group of professionals who are, for the most part, working for their own benefit first and ours second. How about some pictures of club groups and reports on club activities?

With amateur radio being a keystone, to my way of thinking, as far as providing our country with emergency communications, we're talking about club organization, not just individuals. Clubs can help get amateur radio set up so that it will be able to keep going after any kind of disaster. This means cooperative efforts to have both personal and mobile portable equipment, emergency repeaters, automated relaying, low-band interlinks, and—above all—experience. The duty is there, we already have the technology, and the work will be both fun and of help to tie us together, strengthening our clubs and our own value to our communities and country.

Then there is the responsibility of clubs to help amateur radio grow. This means devising schemes to interest teenagers in the hobby through talks at high schools, demonstrations at shopping malls, service for local groups, and participation in things like the March of Dimes. It means making sure that club activities are properly exploited with the local media. When there is a Field Day exercise, the local newspapers and television stations should get the word and be offered cooperation on the story.

Just getting the interest of teenagers isn't enough. Clubs should try to work with school officials to see that there is a radio club in the school which meets at least weekly. Schools have a serious problem about this which clubs can help solve. Any school activity has to have an adult advisor on hand. Since few schools have the budget to pay a teacher for this after-school work, the result has been a serious cutting down of after-school clubs. By providing the needed adult advisor, the local ham club could encourage the development of the school radio club.

Then there is the growing need for license classes to be put on by clubs. One of the really sad results of the Bash cheat-book approach to getting a ham ticket has been the lack of ham club members with even the small technical background it takes to teach the rudiments of theory required for the Novice exam. In some clubs, it is a case of those with scant information trying to teach newcomers, spreading confusion.

All of these problems have been solved by many clubs, so I'd like to see some letters and articles on these subjects for possible publication.

SLEP ELECTRONICS

GIVES TOP TRADE on your used ***ATLAS, COLLINS, DRAKE, ICOM, KENWOOD, TEN-TEC*** amateur gear . . . plus we accept your used solid state ***TEKTRONIX*** and ***HEWLETT-PACKARD*** test equipment, used ***AVIONIC*** equipment, and military surplus avionic and ground electronic equipment.

WE OFFER new factory-boxed latest models of: ***COLLINS, CUBIC/SWAN, DENTRON, DRAKE, ETO, HENRY, ICOM, TEN-TEC***, plus all major antenna and accessory lines.

Tell us what you want and what you have to trade. We'll do the rest.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" x 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

Does anyone have information on RTTY software for a TRS-80 Model I Level II?

Gary Hansen KAØJUM
Route 1 Box 103
Deerwood MN 56444

I am looking for hams with RTTY equipment who would like to help deaf students attending school in Washington DC communicate with their families back home.

Jeffrey A. Meyer N8AHA
26366 Greythorne Trail
Farmington Hills MI 48018

I am looking for a used LCR bridge such as the Leader LCR 740.

Jim Buckwalter WA6FGM
3212 Millcreek
Visalia CA 93291

I need a service manual and schematic diagram for a Hy-Gain Galaxy GT-550-A SSB transceiver. I will pay reasonable copying costs or copy and return.

Jose Sanabrais
Av. Hidalgo No. 99
Queretaro, Qro.
76000 Mexico

I would like to buy the following WWII surplus receivers, in at least good used condition (they need not include power supply, dynamotor, etc.): ARB, RBB (0.5 to 4.0 MHz), and BC-946 (broadcast band ARC-5 receiver).

Meyer Gottesman W6GIV
3377 Solano Avenue, #312
Napa CA 94558

I am blind and bedridden and searching for someone to donate a Kenwood 600 receiver or any other shortwave receiver.

Richard Jastrow
Long Beach General Hospital
2597 Redondo Ave.
Long Beach CA 90806

My club's 5-page Novice-class study guide is offered in exchange for your club's Novice- and/or General-class handouts. Ours is a brief description of the items listed in the current FCC syllabus and has a 95% pass rate in our classes.

Jim Koski KT6W
1714 Austin Avenue
Los Altos CA 94022

*** B E C * Bullet Electronics Corp. P.O. Box 401244E Garland, TX. 75040 (214) 278-3553**

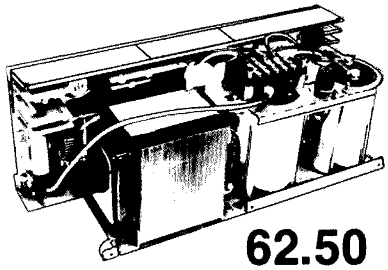
12

THE PRESIDENT SAYS: "HOGWASH!!"

After taking one look at the TRIPUT POWER SUPPLY our engineer declared that the units were worth several hundred dollars each. He pointed out the engineering, high quality construction and state-of-the-art integrated design in support of his position. The President of **BEC** more pragmatically pointed out the already full warehouse and the two trailer truck loads of power supplies waiting in the parking lot, and set the price to move them **QUICKLY!** We have a large quantity, but the supply won't last long. The only thing we ask is *please* read the ordering rules.

QUALITY DOUBLE SIDED GLASS BOARD

REGULATOR ASSEMBLY
(part of unit)



COMPLETE UNIT
(as you receive it)

62.50
Plus Freight
21 lbs.
6 x 5¼ x 12

13.6V @ 20A MODIFICATION

By changing a few parts on the board the Triput Power Supply will do **11 - 14V** (adjustable) at up to **20A.** Perfect for that 2 meter linear amp! We send step by step instructions and necessary parts. **Modification per instructions will not void the 30 day warranty.**

+12V @ 7A; +5V @ 10A; -12V @ 5A

- UNIT IS COMPLETELY ASSEMBLED!
- Fused primary and DC sections
- HUGE SHIELDED TRANSFORMER
- 2% Load & Line Regulation
- Low Ripple (< 100mv)
- Short Circuit Protection
- Overvoltage Protection on all three outputs
- 25A Bridge Rectifier
- Over 60,000 mfd of filters
- High Efficiency **Switching Regulator** reduces heatsink area
- Schematics and service guide included
- Thermal Shutdown
- Statis LED's (3)

ORDERS SHIPPED WITHIN CONTINENTAL U.S. ONLY!

ORDERING RULES

1. Mail check or MO for $62.50 + $5.00 for shipping or phone (214) 278-3553 to charge VISA/MC or COD order. (UPS COD only, add $2.50 COD fee)
2. Texas residents include 5% sales tax.
3. Orders for this unit will be shipped within **48 HOURS** or we pay the freight! (weekends or holidays excluded)
4. **ONE TIME OFFER! LIMIT TWO (2) SUPPLIES PER CUSTOMER.**
